Though no other Greek site has produced terracottas of such artistic merit as the two just discussed, there are others where the art enjoyed great popularity, either for a comparatively brief period or through the whole history of Greek art. Some of these centres of manufacture have already received mention or at least allusion, but we may briefly call attention to a few others. From Sicily we possess a complete series, from archaic to later times, the earlier being best represented at Selinus, where a great variety of richly coloured figures have been found; there are also many fine heads of 5th century style, and later figures of Aphrodite, Eros and other deities imitating the later types of Hellenistic art. At Naukratis in the Egyptian Delta the later terracottas are strongly influenced by Egyptian ideas, and figures like Bes and Horus are found in conjunction with orientalized Aphrodite-types. In the Cyrenaica on the north coast of Africa the influence of Tanagra is apparent, but the style is for the most part degenerate. The terracottas of Tarentum stand apart from those of other sites, being markedly funereal in character; many represent Dionysos reclining at a banquet. Elsewhere in Southern Italy the types correspond to those of Sicily and other Mediterranean sites.

Terracotta work in relief, apart from definitely architectural examples, is almost limited to two small classes, both belonging to the beginning of the 5th century. These groups, known respectively as "Melian" and "Locrian" reliefs, consist of small plaques, possibly intended to be inserted in the walls of temples or shrines. The subjects of the Locrian reliefs, which mostly relate to the myth and cult of Persephone, seem to indicate that they at least were of a votive character. They occur at Locri in Southern Italy, and similar examples dedicated to Athena have been found on the Acropolis at Athens. The Melian reliefs exhibit a wider scope of subjects, mainly mythological; the work is exceedingly delicate and refined in character. Some are simple plaques; others have the figures cut out without background, or only the outer contours. They have been found on various Greek sites, the majority in Melos (Pl. I. fig. 2).

There is a class of vases which comes rather under the heading of terracotta than of pottery, from its technical character and general appearance. These are found at Canosa, Calvi, Cumae and elsewhere in Southern Italy, and belong to the Hellenistic period (Pl. II. fig. 5). They combine in a marked degree the characteristics of the vase and the statuette, some being vases with moulded reliefs or small figures in the round attached; others actual figures or colossal heads modelled in vase form, with the addition of mouth, handle and base. They are often of gigantic size, and do not appear to have served any practical purpose; probably they were made specially for the tomb. They are covered with a white slip like the statuettes, and are often richly coloured. Some even have subjects painted in some permanent process like encaustic. The form usually adopted is that of a spherical vase with a flat handle on the top and three tall mouths.

Etruscan Terracotta Work.—Some features of terracotta work are peculiar to the people of Etruria, who employed this material both for finer works of art and for more utilitarian purposes. Several ancient writers speak of their preference for clay and their skill in its use. Pliny attributes its introduction to Corinthian refugees in the 7th century, and states that the art of modelling in clay was brought to perfection in Italy, and especially in Etruria. Certainly for their statues the Etruscans appear to have preferred clay to other materials (except perhaps bronze), and also for use in architecture. The Romans employed Etruscan artists to decorate their temples, and the statue of Jupiter on the Capitol was made by Volca of Veii about 500 B.C., in clay painted vermilion, as was also the chariot on the pediment of the temple. For the decoration of temples terracotta remained in use even down to Roman times; these buildings being usually of wood covered with slabs of terracotta, like the early Greek buildings discussed in the preceding section. Remains of temples with terracotta decoration of this kind have been found at Cervetri (Caere), at Alatri, and at Civita Castellana (Falerii), as well as at Civita Lavinia (*v. supra*). Other remains of terracotta decorations come from Conca (Satricum), Orvieto, Pitigliano and Luni, where the pediment of the temple has the figures of Olympian deities, muses and the slaughter of Nïobids, all executed in terracotta on a large scale. The date of these sculptures is about 200 B.C. At Alatri and Falerii the decoration consists of a complete system of terracotta plating over the woodwork of the roofs and architraves, ornamented with patterns in relief or painted and surmounted with carved antefixal ornaments. Some of the *antefixae* from Cervetri are very effective examples of sculpture and exhibit in a marked degree the influence of Ionic Greek art, due to the Hellenic elements with which the civilization of Caere and the Campanian cities was permeated.

The form of monument which best exhibits the Etruscan fondness for terracotta as a material for sculpture is the sarcophagus, of which some remarkable archaic examples exist, and a considerable number of later date. Among the former the most conspicuous example is the well-known Castellani sarcophagus in the British Museum, dating from the end of the 6th century B.C. The sides are decorated with friezes of figures in relief, and on the cover is a group of a man and a woman reclining, executed in the round life-size. These figures are undoubtedly genuine native work, and in the obvious inability of the sculptor to achieve success in working in the round they contrast strongly with the reliefs, which are truly Hellenic in style if not in subject. There are similar examples in the Louvre, and in the Museo Papa Giulio at Rome.

The later sarcophagi which belong to the 3rd century B.C. follow on the same lines. They invariably consist of a rectangular body or coffer with sculptured reliefs on the front and sides, and a flat cover on which reclines a figure representing the deceased person. They were used for holding the ashes of the dead. Usually they are of small size, measuring not more than 18 by 12 by 12 in., but some are large enough for a body to lie in at full length. The reliefs freely modelled in the style of later Etruscan art are often of a funerary character, representing the last farewell to the dead in the presence of Charon and other death-deities; others have mythological subjects, such as the combat of Eteokles and Polyneikes; the slaying of the dragon by Kadmos; or the parting of Admetos and Alkestis. They are usually painted *in tempera* on a white ground, the bright colouring having a very vivid effect.

By far the finest examples of this class are one from Cervetri, now in the British Museum, and another very similar in the Archaeological Museum at Florence, with which were found coins of about 150 B.C. The former (Pl. I. fig. 1) is shown by its inscription to be the tomb of one Seianti Thanunia, whose life-size effigy adorns its cover; a most realistic example of Etruscan portrait-sculpture in perfect preservation, richly coloured, and adorned with jewelry. The dimensions of this sarcophagus are 6 ft. by 2 ft. by 1 ft. 4 in.; it has no reliefs on the front but a simple pattern of pilasters and quatrefoils. Owing to its great size the figure of the lady was shaped in two halves, the joint being below the hips. The Florence sarcophagus represents a lady of the name of Larthia Seianti.

Roman Terracotta Work.—The uses of clay among the Romans were much the same as amongst the Greeks and Etruscans, in architecture and sculpture, as well as for other purposes; the main differences were that in some cases its use was more extensive in Rome, in others less; and generally that the products of Roman workshops are inferior to those of earlier times. But the technical processes are in the main those previously employed. The Romans divided the manufacture of objects in clay into two classes: *opus figulinum* for fine ware made from *argilla* or *creta figularis* and *opus doliare* for tiles and common earthenware. Of their use of tiles and bricks in architecture this is not the place to speak, except for the ornamental architectural details which come strictly under the heading of terracotta.

Ornamental tiles followed much on the lines of those used in Greece, whether roof-tiles or antefixal ornaments, though the latter are both simpler and inferior in design. Terracotta was largely used at Pompeii for this purpose, and also for gutters and well mouths. A characteristic feature of Pompeian houses is the trough-like gutter which formed an ornamental cornice to the *compluvium* or open skylight of the *atrium* and peristyle; these were adorned with spouts in the form of masks or animals' heads, through which the rain-water fell from the gutters into the *impluvium*. Some good examples of roof-tiles and antefixal ornaments have also been found at Ostia.

Terracotta mural decoration was also largely employed by the Romans for the interior and exterior of their buildings; in the form of slabs ornamented with reliefs hung on the walls or round the cornices. Cicero speaks of fixing the bas-reliefs (*typos*) "on the cornice of his little atrium." These slabs usually measure about 18 by 9 to 12 in., and have nearly all been found in Rome, though isolated examples occur in other places. There is a series of 160 in the British Museum (Pl. II. fig. 6), whole or fragmentary—nearly all of which were collected at Rome by Charles Towneley—and there is another large collection in the Louvre. Others from the Baths of Caracalla are in various museums at Rome.

These reliefs were pressed in moulds, as is shown by the frequent repetition of certain subjects with at most only slight differences; moreover the relief is low, with sharp and definite outlines such as a mould would produce. They were sometimes retouched before baking, hence the variations. Reliefs entirely modelled are much rarer, but some examples exist, of considerable artistic feeling and freedom. Circular holes are left in the slabs for the plugs by which they were attached in their places. The clay varies in quality and appearance, and in tone ranges from a pale buff to a dark reddish-brown. Traces of colouring are sometimes found; backgrounds of a light blue, and figures or more commonly details such as hair being painted red, yellow, purple or white. These colours are painted *in tempera*, and their use is purely conventional. The slabs are usually ornamental, with cornices of egg-pattern and palmettes, or with an edging of open-work.

The figures are mostly in low relief, grouped with large, flat surfaces between in the manner of contemporary Roman art; in some cases the whole groundwork is composed of patterns of scroll-work or foliage, more or less conventionalized. The compositions consist either of narrow friezes with rows of Cupids or masks, or groups of two or three figures resembling temple-metopes. The style is in general bold and vigorous, and being essentially architectural it is not devoid of dignity and beauty. The known examples fall into two groups according to their treatment: (*a*) The naturalistic style, corresponding to the so-called "Hellenistic" reliefs of Augustan art; (*b*) the conventional, not to say archaistic, corresponding to the classicist tendencies of another school of Augustan artists represented by the "New Attic" reliefs. Both groups find close parallels in the metal-work and pottery of this period, to which date they may therefore be assigned.

The subjects cover a very wide field. Many are no doubt inspired by well-known works of art; others are closely related to the "New Attic" types, including dancing and frenzied *maenads* or the seasons. Others again, reflecting the spirit of the time, reproduce Egyptian landscapes. Scenes from the circus or arena, or quasi-historical subjects, such as triumphs over barbarians, again illustrate favourite themes of Roman Imperial art. Of mythological subjects, the most popular are Dionysiac scenes, Satyrs gathering and pressing grapes, and Victory slaying a bull; while heroic legends are also represented. Of a more conventional type are figures of Cupids carrying wreaths, priestesses sacrificing, or single figures surrounded by elaborate scrolls.

Roman Sculpture in Terracotta.—Frequent allusions in classical writers indicate that the ancient statues of the Romans were mostly of terracotta, and Pliny notes that even in his day statuettes of clay were still preferred for temples. There are also references to *signa fictilia* placed on pediments of buildings such as the Capitoline temple. As noted in the previous section, during the greater part of the Republic, Rome was indebted for these to Etruscan artists, but the style of the figures was probably more Greek than Etruscan. In 493 B.C. Gorgasus and Damophilus of Himera in Sicily ornamented with terracotta reliefs and figures the temple of Ceres (now Santa Maria in Cosmedin). Towards the end of the Republic modellers in clay are mentioned, such as Possis, who imitated grapes and other fruit, and the sculptor Arcesilaus. But their work in this material appears to have been confined to models for sculpture or metal work, and the invasion of the masterpieces of Greek art and the general adoption of marble by sculptors led to the neglect of terracotta as a medium of the glyptic arts. Few statues of any size in this material now exist, but there is an interesting series in the British Museum, found in a well near Porta Latina at Rome in 1767, restored by Nollekens, and acquired by Charles Towneley. Some terracotta figures of considerable size were found at Pompeii, having formed the cult-statues of a temple; others were employed for adorning gardens, like the series from Rome just mentioned. Terracotta figures were also employed as architectural members of the caryatid type. All these belong to the Augustan and succeeding period, or at least are not later than the reign of Nero.

Terracotta statuettes similar in style to those of Greece are also found in houses and tombs of the Roman period or as votive offerings on sacred sites. They were known to the Romans as *Sigilla*, and were used as presents, or placed in the *lararia* or domestic shrines. Some 200 were found in the poorer quarters of Pompeii, implying that they took the place of the marble and bronze figures which the wealthier inhabitants alone could afford. At the festival of Sigillaria, part of the December Saturnalia, terracotta figures and masks were in great demand. Originally these were votive offerings to Saturn, but later the custom degenerated into that of giving them as presents to friends or children, a practice indulged in by the Emperors Hadrian and Caracalla.

The makers of these figures were known as *sigillarii* or *figuli sigillatores*, and they lived in the *Via Sigillaria*. Their social position appears to have been very low; but it must be remembered that they were chiefly patronized by the poorer classes; probably many of them were slaves. The technical processes which they employed were practically those of the Greek craftsmen. Large figures were made from models (*proplasmata*) and built up on a wooden frame-work known as *crux* or *stipes*; but the smaller ones were made from moulds. The range of subjects is much the same as in the later Greek terracottas. At Pompeii *genre* figures predominate, such as gladiators, athletes and slaves, and in general there is a preference for portraits and grotesques. On the whole these late works have little artistic merit. Votive figures have been found at Praeneste on the site of the temple of Fortune, and also at Nemi and Gabii.

This industry also extended from Rome to the provinces, and terracotta statuettes of local make have been found even in Britain, as at Richborough, Colchester and London. In Gaul in particular, and in the Rhine district, there were very extensive manufactures of terracottas after the conquest of Julius Caesar in 58 B.C. They were made by local craftsmen for the Roman colonists, who introduced their own types of design. The principal centre of manufacture was the district of the Allier in Central France. Potteries have been found at Moulins, as well as in other parts of France, in Belgium and Alsace, and along the Rhine. The figures found in the Allier district are made of a peculiar white clay, the technique resembling that of Roman work, but the modelling is heavy and often barbaric. Numerous moulds have also come to light which show that the figures were made in two pieces; on the exterior of these moulds the potters' names have frequently been scratched (to indicate ownership). Names appear on the figures as well as on the moulds, and many of these are of Gaulish origin. The commonest names are those of Pistillus of Autun, Rextugenus, a potter of north-west France, and Vindex of Cologne. The subjects include divinities, *genre* figures, and animals; among the former the pre-eminent type is that of a Nature-Goddess, characterized either as Venus Genetrix or as a Mother with a Child (*κουροτρόφος*). Both in subject and in artistic character these statuettes appear to have been largely influenced by the *Graeco-Egyptian* art of Alexandria during the Hellenistic period. They appear to have been used for domestic and funerary purposes and as votive offerings.

After the downfall of the Roman Empire in the west, the artistic use of terracotta was abandoned for many centuries, though, here and there, both in Italy and in the districts that had been once Roman provinces, decorated terracotta work was carried on sporadically both in parts of France and of Germany. The true renaissance of its use came during the 14th and 15th centuries, when it was adapted once more to architectural service in the Gothic buildings of northern Italy and of Germany. In Germany the mark of Brandenburg is especially rich in buildings enriched with modelled terracotta. The church of St Catherine in the town of Brandenburg is decorated in the most lavish way with delicate tracery and elaborate string-courses and cornices enriched with foliage all modelled in clay; the town-hall of Brandenburg is another instance of the same use of terracotta. At Tangermünde, the church of St Stephen and other buildings of the beginning of the 15th century are wonderful examples of this method of decoration; the north door of St Stephen's especially being a masterpiece of rich and effective moulding. In northern Italy this use of terracotta was carried to an equally high pitch of perfection. The western façade of the cathedral of Crema, the communal buildings of Piacenza, and S. Maria delle Grazie in Milan are all striking examples of the extreme splendour of effect that can be obtained by terracotta work. The Certosa near Pavia is a gorgeous specimen of the early work of the 16th century; the two cloisters are especially magnificent. Pavia itself is very rich in terracotta decoration, especially the ducal palace and the churches of S. Francesco and S. Maria del Carmine. Some delicate work exists among the medieval buildings of Rome, dating from the 14th and 16th centuries, as, for example, the rich cornices of the south aisle of S. Maria in Ara Coeli, *c.* 1300; the front of S. Cosimato in Trastevere, built *c.* 1490; and a once very magnificent house, near the Via di Tordinone, which dates from the 14th century.

With the revival of terracotta as an adjunct to medieval architecture we find the sculptors of the Italian renaissance turning to this material, as a medium for the production of reliefs, busts, and even groups of many life-sized figures—again following the practice of classic times. Much of the Florentine terracotta sculpture of the 15th century is among the most beautiful plastic work the world has ever seen, especially that by Jacopo della Quercia, Donatello, and the sculptors of the next generation.[1] For life, spirit, and realistic truth, combined with sculpturesque breadth, these pieces are masterpieces of invention and manipulation. The portrait busts are perfect models of iconic sculpture. In some respects the use of burnt clay for sculpture has great advantages over that of marble; the soft clay is easily and rapidly moulded into form while the sculptor's thought is fresh in his mind, and thus works in terracotta often possess a spirit and vigour which can hardly be reproduced in laboriously finished marble. In the 16th century a more realistic style was introduced, and this was heightened by the custom of painting the figures in oil colours. Many very clever groups of this kind were produced by Ambrogio Foppa (Caradosso) for S. Satiro at Milan and by Guido Mazzoni and Begarelli (1479–1565) for churches in Modena. These terracotta sculptures are unpleasing in colour and far too pictorial in style; but those of Begarelli were enthusiastically admired by Michelangelo. The introduction of enamelled reliefs in terracotta which is so closely associated with the Florentine sculptor Luca della Robbia and his descendants, is specially treated in the article DELLA ROBBIA (*q.v.*).

From these two centres the development of architectural terracotta gradually spread over western Europe. The German school influenced the work done in the Low Countries and finally in England, where it also met the direct influence of the Italian school due to the invasion of England by Italian artists such as Torrigiano and others who were invited to England during the reigns of Henry VII. and Henry VIII. It is only in the eastern and southern counties of England that we find instances of the terracotta work of this period, and much of it is so un-English in style that most authorities consider it was not made in England at all but was imported from Holland or Flanders. Essex possesses the finest examples; such as those to be found in the Manor House at Layer Marney, and a richly-decorated terracotta tomb in the church at the same place, both dating from the reign of Henry VIII.

In the Collegiate Church at Wymondham in Norfolk there are very large and elaborate sedilia with canopied niches all of terracotta of the same period and apparently of the same manufacture. The unsettlement which followed the Reformation in England and continued during the Stuart period seems to have put an end to this imported art, and it is only in modern times that we find a revival of architectural terracotta work in England.

France.—Another offshoot from the fertile plains of northern Italy was implanted in France during the 16th century. Many sculptors from northern and central Italy were attracted to France by Francis I. and his successors, and, among other arts, they introduced the making of artistic terracottas. The most famous name in the lists of these Italian artists is that of Girolamo della Robbia (see article DELLA ROBBIA), who executed, in 1529, the enamelled terracotta for the decoration of the "Petit Château de Madrid" in the Bois de Boulogne, Paris, for Francis I.[2] Many other Italian artists of lesser repute imported their arts into France, and the British Museum possesses an embossed tile bearing the head of St John the Baptist, encircled by a Gothic inscription, which was evidently made at Lyons during the 16th century. The very mould of this tile, together with other subjects of similar type, was excavated at Lyons and, while it is probable that the workmanship was Italian, the style of the modelling is entirely French in character.

Spain.—At about the same period the Italian modellers or sculptors carried the art into Spain, and many extraordinary works are still extant in various Spanish churches remarkable for their vivid realism and for a too pictorial style which degrades them from their true rank as architectural decoration.

During the 17th and 18th centuries the architectural use of terracotta again fell away owing to the increasing use of marble, but that the art still survived in other forms is shown by the portrait busts of Dwight (17th century), though they were made in stoneware and not in unglazed terracotta; and the charming little statuettes and groups made in Lorraine and the adjacent parts of France by Guibal, Cyfflé and Lemire, sculptors employed at some of the pottery factories of the period.

It should be mentioned that during the 18th century ordinary clay had fallen into disrepute, but the porcelain figures made at Meissen, Sèvres and other continental factories show how persistent the vogue of figure-modelling in clay had become—though the clay was porcelain clay and not ordinary terracotta (see CERAMICS).

Modern.—During the last fifty years there has been throughout Europe a great revival in the manufacture of terracotta, both glazed and unglazed. We have in England, for example, some very important buildings, such as the Natural History Museum, the Albert

[1] The Victoria and Albert Museum has a splendid and representative collection of these Italian terracottas.

[2] This last and most extensive of the works in terracotta executed by the Robbia family was destroyed during the French Revolution in 1792, but exact drawings of it are still in existence showing all the necessary details.

Hall, and the Royal College of Science, all in South Kensington, London, which illustrate to perfection the English terracotta work of the mid-Victorian period. The Rijks Museum at Amsterdam, and many important buildings in the north of Germany, in Belgium and in France, display the increasing use of baked clay for architectural purposes.

The effort of all terracotta makers during recent times has been to produce a building material capable of resisting the acids and soot contained in the atmosphere of our great towns. Technically many of the leading manufacturers in England and the continental countries have been very successful in this effort, as they are able to produce building materials of pleasant colour and texture which are practically acid-resisting. Critics of this modern development of terracotta as a building material frequently complain of the want of truth in the lines of cornices, door or window jambs, &c. For this default the manufacturer is not so much to blame as are those modern architects who design a building for stone construction and then decide to have it executed in terracotta. The shrinkage of clay both in drying and firing is well known, and it is this shrinkage which causes large pieces of terracotta to twist or become crooked. When our modern architects shall have realized that the details of a building must be designed specially for the material that is to be used in its construction, terracotta will come into its own again as a decorative building material. The present method of constructing buildings in reinforced concrete, faced with glazed or unglazed terracotta, will afford the architects of the 20th century an unrivalled opportunity for the use of this material.

Collections.—The Louvre, British Museum, and the museums of Berlin and Athens have remarkably fine collections of the Greek and Roman terracottas, and many provincial museums, such as those of Florence, Perugia, Rome, Naples, Nîmes and Arles, have also collections of importance. The best collections of Greek terracotta figures are in the British Museum, the Louvre and the museums of Berlin and Athens; but a large number of the finest Greek terracotta figures are in private collections. In the Victoria and Albert Museum there is a remarkable collection of fine Florentine terracottas of the best periods.

(W. B.*; H. B. WA.)

TERRAMARA (from Ital. *terra marna*, "marl"), the name given by archaeologists[1] to a type of primitive culture mainly of the early bronze age, but stretching back into the later stone age. This civilization is represented by a number of mounds, formerly thought (*e.g.* by Venturi) to be sepulchral, but really the remains of human habitations, analogous to shell heaps (*q.v.*) or kitchen middens. They are found chiefly in north Italy, in the valley of the Po, round Modena, Mantua and Parma. A summary of early results as to these mounds was published by Munro (*Lake Dwellings*) in 1890, but scientific investigation really began only with the excavation of the terramara at Castellazzo di Fontanellato (province of Parma) in 1889. From this and succeeding investigations certain general conclusions have been reached. The terramara, in spite of local differences, is of typical form; it is a settlement, trapezoidal in form, built upon piles on dry land protected by an earthwork strengthened on the inside by buttresses, and encircled by a wide moat supplied with running water. The east and west sides are parallel, and two roads at right angles divide the settlement into four quarters. Outside are one or two cemeteries. Traces of burning which have been found render it probable that, when the refuse thrown down among the piles had filled the space, the settlement was burned and a new one built upon the remains. The origin of the terramara type is not definitely ascertained. The most probable inference, however, is that these settlements were not built to avoid the danger of inundation, but represent a survival of the ordinary lake dwelling.

The remains discovered may be briefly summarized. Stone objects are few. Of bronze (the chief material) axes, daggers, swords, razors and knives are found, as also minor implements, such as sickles, needles, pins, brooches, &c. There are also objects of bone and wood, besides pottery (both coarse and fine: see CERAMICS), amber and glass-paste. Small clay figures, chiefly of animals (though human figures are found at Castellazzo), are interesting as being practically the earliest specimens of plastic art found in Italy.

The occupations of the terramara people as compared with their neolithic predecessors may be inferred with comparative certainty. They were still hunters, but had domesticated animals; they were fairly skilful metallurgists, casting bronze in moulds of stone and clay; they were also agriculturists, cultivating beans, the vine, wheat and flax. According to Prof. W. Ridgeway (*Who were the Romans?* p. 16; and *Early Age of Greece*, i. 496) burial was by inhumation: investigation, however, of the cemeteries shows that the bodies were burned and the ashes placed in ossuaries; practically no objects were found in the urns.

Great differences of opinion have arisen as to the origin and ethnographical relations of the terramara folk. Brizio in his *Epoca Preistorica* advances the theory that they were the original Ibero-Ligurians who at some early period took to erecting pile-dwellings. Why they should have done so is difficult to see. Some of the terremare are clearly not built with a view to avoiding inundation, inasmuch as they stand upon hills. The rampart and the moat are for defence against enemies, not against floods, and as Brizio brings in no new invading people till long after the terramara period, it is difficult to see why the Ibero-Ligurians should have abandoned their unprotected hut-settlements and taken to elaborate fortification. There are other difficulties of a similar character. Hence Pigorini regards the terramara people as an Aryan lake-dwelling people who invaded the north of Italy in two waves from Central Europe (the Danube valley) in the end of the stone age and the beginning of the bronze age, bringing with them the building tradition which led them to erect pile dwellings on dry land. These people he calls the Italici, to whom he attributes also the culture known as *Villanova* (*q.v.*). This view

[1] Since the International Congress of Prehistoric Archaeology at Bologna in 1871, when the shortened form *terramara* (plur. *terremare*) was adopted.

is regarded as falling in with discoveries (somewhat incomplete, it is true) in Hungary and Bosnia.

AUTHORITIES.—All the evidence is collected by T. E. Peet, *The Stone and Bronze Ages in Italy and Sicily* (Oxford, 1909), xiv. and xviii., which gives illustrations and references to the more important literature; this work supersedes all previous works on the *terremare*. Prof. Pigorini's article, "Le più antiche civiltà dell' Italia," in *Bullettino di paletnologia italiana*, xxix., is classical. See also the works of Montelius, Modestov, and Ridgeway (*Early Age of Greece*, vol. i.). (J. M. M.)

TERRANOVA, a town of Sicily, on the S. coast, in the province of Caltanisetta, 74 m. by rail and 41 m. direct E.S.E. of Girgenti. Pop. (1901) 22,019. The poorly built modern town contains no buildings of interest or importance; it stands on a sand-hill near the sea, with a fertile plain (the ancient *Campi Geloi*) to the N. of it. It has some trade but no port, only an open roadstead. It almost certainly occupies the site of the ancient Gela (*q.v.*). Outside it on the E. are scanty remains of a Doric temple (480–440 B.C.?) of which a single pillar only remains, which was still standing in the 18th century (height about 26½ ft., lower diameter 5⅝ ft.); here some painted decorative terracottas have been found (see Orsi in *Atti del Congresso di Scienze Storiche*, Rome, 1904, v. 188). Between it and the modern town the stylobate of a large temple was found in 1906. This seems to have been constructed towards the end of the 7th century B.C. on the site of a still earlier edifice. The stylobate measures 115 by 58 ft. A large number of decorative terracottas were found, among them a small helmeted head of Athena: her name recurs upon the lip of a large *pilhos*, and it is probable that the temple was dedicated to her. There is no trace of any object that can be dated after the end of the 6th century B.C., and it is therefore probable that this temple was destroyed when the other was constructed, and that the latter also was dedicated to Athena. On the W. of the town, on the Capo Soprano, was the ancient necropolis, where many tombs of the Greek period have been discovered; the objects found, including many fine Attic vases, are partly in private collections at Terranova itself, partly in foreign museums, while the results of later excavations, including some large terracotta sarcophagi, are in the museum at Syracuse.

See Orsi in *Notizie degli scavi*, 1901, 307; 1902, 408; 1907, 38.

TERRANOVA PAUSANIA, a seaport of Sardinia, in the province of Sassari, situated on the E. coast, 14 m. S.W. of Golfo Aranci, and 72 m. E. of Sassari by rail, and in the innermost recess of the sheltered gulf of Terranova. Pop. (1901) 4348. It occupies the site of the ancient Olbia (*q.v.*), and until the traffic was transferred to Golfo Aranci, was the port of embarkation for Italy, as in ancient times. There is some trade in cork and charcoal. The place is low-lying and malarious. The only building of interest is the Romanesque church of S. Simplicio, once the cathedral, which as it stands dates probably from the 11th century. It was the seat of the *giudici* of Gallura, sent here by the Pisans in the 11th century (but probably the native *giudici* resided at Tempio), and of an episcopal see, united in 1506 with that of Ampurias. The name Pausania is the consequence of an error; it is a corruption of Fausiana, a town and episcopal see of Sardinia mentioned by Gregory the Great, the site of which is in reality uncertain.

TERRE HAUTE, a city and the county-seat of Vigo county, Indiana, U.S.A., on the eastern bank of the Wabash river, about 186 m. S. by E. of Chicago and about 73 m. W. by S. of Indianapolis. Pop. (1890) 30,217; (1900) 36,673, of whom 1520 were negroes and 2952 foreign-born; (1910, census) 58,157. Land area (1906), 8·25 sq. m., of which nearly one-third had been annexed since 1890 and a considerable part since 1900. It is served by the Chicago & Eastern Illinois, the Cleveland, Cincinnati, Chicago & St Louis, the Evansville & Indianapolis, the Evansville & Terre Haute, the Southern Indiana, the Vandalia and several electric interurban railways. It is finely situated on high ground 60 ft. above the river level, and has wide, well-paved streets shaded by oaks and elms. It is the seat of the Indiana State Normal School (1870), which had in 1909 a library of about 50,000 volumes, 52 instructors and an average term enrolment of 988 students, and of the Rose Polytechnic Institute, which was founded in 1874 by Chauncey Rose (1794–1877), was opened in 1883, offers courses in mechanical, electrical, civil and chemical engineering and in architecture, and in 1909 had 22 instructors and 214 students. About 4 m. W. of Terre Haute is St Mary-of-the-Woods (founded in 1840 by the Sisters of Providence, and chartered in 1846), a school for girls. The Emeline Fairbanks Memorial Library (1882) contained 30,000 volumes in 1910, housed in a building erected in 1903 by Mr Crawford Fairbanks in memory of his mother. Terre Haute's industrial and commercial importance is largely due to its proximity to the valuable coal-fields of Clay, Sullivan, Park, Vermilion, Greene and Vigo counties. The total value of its factory product in 1905 was $29,291,654; both in 1900 and in 1905 it ranked second among the manufacturing cities of the state. It is the largest distilling centre in the state and one of the largest in the country, the value of the output of this industry in 1905 being more than half the total value of the city's factory product for the year. The value of the glass product in 1905 was 4·4 per cent. of the value of all factory products of the city, and 1·6 per cent. of the value of all glass manufactured in the United States.

The first settlers at Terre Haute built their cabins near Fort Harrison, which was erected by command of Governor William Henry Harrison in the winter of 1810–11. In 1812 the fort was successfully defended against an attack of the Indians by its commandant Captain Zachary Taylor, and in 1817 was abandoned. After the close of the War of 1812 the town grew rapidly and became an important commercial centre, owing to its river connexions and to the fact that the National (or Cumberland) Road crossed the Wabash here. Terre Haute was incorporated as a town in 1838, became a city in 1853 (under a general state law of June 1852), received a special city charter in 1899, in 1905 was organized as a city of the third class, and became a city of the second class in 1909.

TERRELL, a city of Kaufman county, Texas, U.S.A., about 32 m. E. of Dallas. Pop. (1890) 2988; (1900) 6330 (1517 negroes); (1910) 7050. Terrell is served by the Texas & Pacific and the Texas Midland railways. The city is the seat of Wesley College (Methodist Episcopal, South), until 1909 the North Texas University School, and of the North Texas Hospital for the Insane (1885), and has a Carnegie library. It is situated in a rich farming region. The city has a cotton compress and cotton-gins, and various manufactures. The Texas Midland railway has shops and general offices here. Terrell, named in honour of Robert A. Terrell, an early settler, was founded in 1872 and was chartered as a city in 1874.

TERRISS, WILLIAM (1847–1897), English actor, whose real name was William Charles James Lewin, was born in London on the 20th of February 1847. After trying the merchant service, medicine, sheep-farming in the Falkland Isles, and tea-planting in Bengal, in 1867 he took to the stage, for which his handsome presence, fine voice and gallant bearing eminently fitted him. His first appearance in London was as Lord Cloudrays in Robertson's *Society*, at the old Prince of Wales's theatre. He quickly came into favour in "hero" parts, and appeared at the principal London theatres from 1868 onwards. In 1880 he joined Irving's company at the Lyceum, playing such parts as Cassio and Mercutio, and in 1885 he acted there with Mary Anderson, as Romeo to her Juliet, &c. He was then engaged to take the leading parts in Adelphi melodrama, and it was in this capacity that for the rest of his career he was best known, though he occasionally acted elsewhere, notably with Irving at the Lyceum. His last appearance was in *Secret Service*. On the 16th of December 1897, as he was entering the Adelphi theatre, he was stabbed to death by a madman, Richard Arthur Prince. Terriss married Miss Isabel Lewis, and his daughter Ellaline Terriss (Mrs Seymour Hicks) became a well-known actress in musical comedy, in association with her husband Edward Seymour Hicks (*b.* 1871), proprietor of the Aldwych and Hicks theatres in London.

See Arthur J. Smythe, *The Life of William Terriss* (London, 1898).

TERRY, EDWARD O'CONNOR (1844–), English actor, was born in London, and began his stage career in a small and struggling way in the provinces. Between 1868 and 1875 he was the leading comedian at the Strand theatre, London, but it was not till he joined Hollingshead's company at the Gaiety in 1876 that he became a public favourite in the burlesques produced there during the next eight years. With Nellie Farren, Kate Vaughan and Royce, he made the fortune of this house, his eccentric acting and singing creating a style which had many imitators. In 1887 he went into management, opening Terry's theatre, where his production of Pinero's *Sweet Lavender* was a great success. But in subsequent years he was only occasionally seen at his own theatre, and made many tours in the provinces and in Australia, America and South Africa. Off the stage he was well known as an ardent Freemason, and an indefatigable member of the councils of many charities and of public bodies.

TERRY, ELLEN ALICIA (1848–), English actress, was born at Coventry on the 27th of February 1848. Her parents were well-known provincial actors, and her sisters Kate, Marion and Florence, and her brother Fred, all joined the theatrical profession, and her own first appearance on the stage was made on the 28th of April 1856, under the Keans' management, as the boy Mamilius in *The Winter's Tale*, at the Princess's theatre, London. Two years later she played Prince Arthur in *King John* with such grace as to win high praise. From 1860 to 1863 and again from 1867 to 1868 she acted with various stock companies. During this period she played, on the 26th of December 1867, for the first time with Henry Irving, being cast as Katharine to his Petruchio in Garrick's version of *The Taming of the Shrew* at the Queen's theatre. When quite a girl she married G. F. Watts the painter, but the marriage was soon dissolved. Between 1868 and 1874, having married E. A. Wardell, an actor whose professional name was Charles Kelly, she was again absent from the stage, but she reappeared in leading parts at the Queen's theatre under Charles Reade's management. On the 17th of April 1875 she played Portia for the first time in an elaborate revival of *The Merchant of Venice* under the Bancrofts' management at the old Prince of Wales's theatre. This was followed by a succession of smaller triumphs at the Court theatre, culminating in her beautiful impersonation of Olivia in W. G. Wills's dramatic version of Goldsmith's *Vicar of Wakefield*, in 1878, the result of which was her engagement by Henry Irving as his leading lady for the Lyceum theatre, and the beginning of a long artistic partnership, in the success of which Miss Terry's attractive personality played a large part. Her Shakespearean impersonations at the Lyceum were Ophelia in 1878, Portia in 1879, Desdemona in 1881, Juliet and Beatrice in 1882, Viola in 1884, Lady Macbeth in 1888, Katherine, in *Henry VIII.*, and Cordelia in 1892, Imogen in 1896, and Volumnia, in *Coriolanus*, in 1901. Other notable performances were those of the Queen in Wills's *Charles I.* in 1879, Camma in Tennyson's *The Cup* in 1881, Margaret in Wills's *Faust* in 1885, and the title-part in Charles Reade's one-act play *Nance Oldfield* (1893), Rosamund in Tennyson's *Becket* (1893), Madame Sans-Gêne in Sardou's play (1897), and Clarisse in *Robespierre* (1899). With the Lyceum company she several times visited the United States. In 1902, while still acting with Sir Henry Irving, she appeared with Mrs Kendal in Beerbohm Tree's revival of *The Merry Wives of Windsor*, at His Majesty's theatre, and she continued, after Sir Henry Irving's death, to act at different theatres, notably at the Court theatre (1905) in some of G. Bernard Shaw's plays. In 1906 her stage-jubilee was celebrated in London with much enthusiasm, a popular subscription in England and America resulting in some £8000 being raised. In 1907 Miss Terry married James Carew, an American actor.

Her sister Marion Terry (b. 1856) became only less distinguished on the English stage than herself; and her brother Fred Terry (b. 1865) also became a leading actor, and a successful manager in association with his wife, the actress Julia Neilson.

See Charles Hiatt, *Ellen Terry and her Impersonations* (1898); Clement Scott, *Ellen Terry*.

TERSTEEGEN, GERHARD (1697–1769), German religious writer, was born on the 25th of November 1697, at Mörs, at that time the capital of a countship belonging to the house of Orange-Nassau (it fell to Prussia in 1702), which formed a Protestant *enclave* in the midst of a Catholic country. After being educated at the gymnasium of his native town, Tersteegen was for some years apprenticed to a merchant. He soon came under the influence of Wilhelm Hoffman, a pietistic revivalist, and devoted himself to writing and public speaking, withdrawing in 1728 from all secular pursuits and giving himself entirely to religious work. His writings include a collection of hymns (*Das geistliche Blumengärtlein*, 1729; new edition, Stuttgart, 1868), a volume of *Gebete*, and another of *Briefe*, besides translations of the writings of the French mystics. He died at Mühlheim in Westphalia on the 3rd of April 1769.

See Hymns, and the article by Eduard Simons in Herzog-Hauck, *Realencyklopädie*, vol. xix. (ed. 1907).

TERTIARIES (Lat. *tertiarii*, from *tertius*, third), associations of lay folk in connexion with the Mendicant Orders. The old monastic orders had had attached to their abbeys confraternities of lay men and women, going back in some cases to the 8th century. The Confraternity Book of Durham is extant and embraces some 20,000 names in the course of eight centuries. Emperors and kings and the most illustrious men in church and state were commonly confraters of one or other of the great Benedictine abbeys. (On this subject see article by Edmund Bishop in *Downside Review*, 1885.) The confraters and consorors were made partakers in all the religious exercises and other good works of the community to which they were affiliated, and they were expected in return to protect and forward its interests; but they were not called upon to follow any special rule of life.

Although something of the kind existed among the Humiliati in the 12th century, the institution of Tertiaries arose out of the Franciscan movement. It seems to be certain that St Francis at the beginning had no intention of forming his disciples into an Order, but only of making a great brotherhood of all those who were prepared to carry out in their lives certain of the greater and more arduous of the maxims of the Gospel. The formation of the Franciscan Order was necessitated by the success of the movement and the wonderful rapidity with which it spread. When the immediate disciples of the saint had become an order bound by the religious vows, it became necessary to provide for the great body of laity, married men and women, who could not leave the world or abandon their avocations, but still were part of the Franciscan movement and desired to carry out in their lives its spirit and teaching. And so, probably in 1221, St Francis drew up a Rule for those of his followers who were debarred from being members of the order of Friars Minor. At first they were called "Brothers and Sisters of the Order of Penance"; but later on, when the Friars were called the "First Order" and the nuns the "Second Order," the Order of Penance became the "Third Order of St Francis"—whence the name Tertiaries: this threefold division already existed among the Humiliati.

In 1901 Paul Sabatier published a "Rule of Life of the Brothers and Sisters of Penance," which probably contains, with additions, the substance of the original Rule of 1221. It prescribes severe simplicity of dress and of life, and certain abstinences and prayers and other religious exercises, and forbids the frequentation of the theatre, the bearing of arms and the taking of oaths except when administered by magistrates. In 1289 Nicholas IV. approved the Third Order by a Bull, but made some alterations in the Rule, and this form of the Rule remained in force until our own day.

Immediately on its establishment in 1221 the Third Order spread with incredible rapidity all over Italy and throughout western Europe, and embraced multitudes of men and women of all ranks from highest to lowest. Everywhere it was connected closely with the First Order, and was under the control of the Friars Minor.

In time a tendency set in for members of the Third Order to live together in community, and in this way congregations were formed who took the usual religious vows and lived a fully organized religious life based on the Rule of the Third Order with supplementary regulations. These congregations are the "Regular Tertiaries" as distinguished from the "Secular Tertiaries," who lived in the world, according to the original idea. The Regular Tertiaries are in the full technical sense "religious," and there have been, and are, many congregations of them, both of men and of women.

There can be little doubt, whatever counter claims may be set up, that the Third Order was one of St Francis' creations, and that his Third Order was the exemplar after which the others were fashioned; but at an early date the other Mendicant Orders formed Third Orders on the same lines, and so there came into being Dominican Tertiaries, and Carmelite, and Augustinian, and Servite, and also Premonstratensian and many others. These followed the same lines of development as the Franciscan Tertiaries, and for the most part divided into the two branches of regular and secular Tertiaries. The Rules of the various Third Orders have proved very adaptable to the needs of modern congregations devoted to active works of charity; and so a great number of teaching and nursing congregations of women belong to one or other of the Third Orders.

The Franciscan Third Order has always been the principal one, and it received a great impetus and a renewed vogue from Leo XIII., who in 1883 caused the Rule to be recast and made more suitable for the requirements of devout men and women at the present day. In consequence it is estimated that the number of lay Franciscan Tertiaries now exceeds two millions.

BIBLIOGRAPHY.—The most serviceable authority on the Franciscan Tertiaries is probably Max Heimbucher, *Orden und Kongregationen* (1907), ii. §§ 103, 104, 105, where an ample bibliography is supplied. The same work gives information on the other Tertiaries at the end of the sections on the various Orders. Similarly information will be found in Helyot, *Histoire des Ordres religieux* (1714), after the chapters on the different Orders. Heimbucher names Tachy, *Les Tiers Ordres* (1897), and Adderley and Marson, *Third Orders* (1902). (E. C. B.)

TERTIARY, in geology, the time-division which includes the Eocene, Oligocene, Miocene and Pliocene periods, in other words, it is the earlier portion of the Cainozoic era. By some authorities the term Tertiary is made to embrace in addition to the foregoing periods those of the Quaternary (Pleistocene and Holocene), *i.e.* "Tertiary" is made the equivalent of Cainozoic. On logical grounds there is much in favour of this interpretation; but having in view the state of geological literature, it is certainly better to restrict the use of the term in the manner indicated above. Tertiary rocks were among the latest to receive the careful attention of geologists, and the name was introduced by G. Cuvier and H. Brongniart in 1810 (*Essai sur la géographie minéralogique des environs de Paris*, 1810–11, 1st ed.).

Deshayes (1830) worked out the percentages of recent fossils found at several horizons in those strata, and upon this Sir C. Lyell (1852) founded the main periods, viz. the Eocene with 3½ per cent. of recent forms, Miocene 17 per cent., Pliocene 35 to 50 per cent. Subsequent investigations naturally modified the numerical values upon which this nomenclature was based, but without altering the order of the periods. Later, E. Beyrich introduced the Oligocene period, and some geologists recognize a Palaeocene or early Eocene period. European geologists very generally use the grouping adopted by R. Hörnes:—

Younger Tertiary = Neogene (Miocene, Pliocene).

Older Tertiary = Palaeogene (Palaeocene, Eocene, Oligocene).

The great number and variety of mammalian remains has made it possible for the Tertiary rocks to be classified by their means: see A. Gaudry, *Les enchaînements du monde animal—mammifères Tertiaires* (1878); W. B. Dawkins, *Q. J. Geol. Soc. Lond.* (1880); Forsyth Major, *Geol. Mag.* (London, 1899); and H. F. Osborn, J. L. Wortman, G. F. Matthew, for western North America, *Bull. Am. Mus. Nat. Hist.*, xii. (1899).

During the Tertiary era the geographical configuration of the globe was steadily approaching that of the present day; but in the earlier part of the time there still existed the great equatorial ocean "Tethys," and there is evidence that East India and Africa, Australia and Asia, north Europe and North America were probably severally united by land connexions. As the period advanced, along the very line that had been occupied by the nummulitic sea (Tethys) the crust began to be folded up, giving rise to the Alps, Carpathians, Caucasus, Himalayas and other mountains, some of the early Tertiary marine formations being now found raised more than 16,000 ft. above the present level of the sea. Associated with these crustal movements were enormous outpourings of volcanic materials.

The faunal aspect of the Tertiary periods differs strikingly from that of preceding Secondary or Mesozoic; in place of the great saurian reptiles we find the rapid development and finally the maximum expansion of mammals. Snakes and true birds advanced rapidly towards their modern position. In the seas, bony fish and crab-like decapods increased in numbers and variety, while pelecypods and gasteropods took the prominent place previously occupied by ammonites and belemnites, and, leaving behind such forms as *Rudistes*, *Inoceramus*, &c., they gradually developed in the direction of the modern regional groups. In the plant world, the dicotyledonous angiosperms gradually assumed the leading rôle which they occupy to-day.

The climate in northern latitudes seems to have passed from temperate to sub-tropical, with minor fluctuations, until at the close a rapid lowering of temperature ushered in the glacial period. (J. A. H.)

TERTULLIAN (*c.* 155–*c.* 222), whose full name was QUINTUS SEPTIMIUS FLORENS TERTULLIANUS, is the earliest and after Augustine the greatest of the ancient church writers of the West. Before him the whole Christian literature in the Latin language consisted of a translation of the Bible, the *Octavius* of Minucius Felix (*q.v.*)—an apologetic treatise written in the Ciceronian style for the higher circles of society, and with no evident effect for the church as a whole, the brief Acts of the Scillitan martyrs, and a list of the books recognized as canonical (the so-called Muratorian fragment). Whether Victor the Roman bishop and Apollonius the Roman senator ever really made an appearance as Latin authors is quite uncertain. Tertullian in fact created Christian Latin literature; one might almost say that that literature sprang from him full-grown, alike in form and substance, as Athena from the head of Zeus. Cyprian polished the language that Tertullian had made, sifted the thoughts he had given out, rounded them off, and turned them into current coin, but he never ceased to be aware of his dependence on Tertullian, whom he designated as κατ' ἐξοχήν, his master (Jer., *De vir. ill.* 53). Augustine, again, stood on the shoulders of Tertullian and Cyprian; and these three North Africans are the fathers of the Western churches.

Tertullian's place in universal history is determined by (1) his intellectual and spiritual endowments, (2) his moral force and evangelical fervour, (3) the course of his personal development, (4) the circumstances of the time in the midst of which he worked.

(1) Tertullian was a man of great originality and genius, characterized by the deepest pathos, the liveliest fancy, and the most penetrating keenness, and was endowed with ability to appropriate and make use of all the methods of observation and speculation, and with the readiest wit. His writings in tone and character are always alike "rich in thought and destitute of form, passionate and hair-splitting, eloquent and pithy in expression, energetic and condensed to the point of obscurity." His style has been characterized with justice as dark and resplendent like ebony. His eloquence was of the vehement order; but it wins hearers and readers by the strength of its passion, the energy of its truth, the pregnancy and elegance of its expression, just as much as it repels them by its heat without light, its sophistical argumentations, and its elaborate hair-splittings. Though he is wanting in moderation and in luminous warmth, his tones are by no means always harsh; and as an author he ever aspired with longing after humility and love and patience, though his whole life was lived in the atmosphere of conflict. Tertullian both as a man and as a writer had much in common with the apostle Paul.

(2) In spite of all the contradictions in which he involved

himself as a thinker and as a teacher, Tertullian was a compact ethical personality. What he was he was with his whole being. Once a Christian, he was determined to be so with all his soul, and to shake himself free of all half measures and compromises with the world. It is not difficult to lay one's finger upon very many obliquities, self-deceptions and sophisms in Tertullian in matters of detail, for he struggled for years to reconcile things that were in themselves irreconcilable; yet in each case the perversities and sophisms were rather the outcome of the peculiarly difficult circumstances in which he stood. It is easy to convict him of having failed to control the glowing passion that was in him. He is often outrageously unjust in the substance of what he says, and in manner harsh to cynicism, scornful to gruesomeness; but in no battle that he fought was he ever actuated by selfish interests. What he did was really done for the Gospel, as he understood it, with all the faculties of his soul. But he understood the Gospel as being primarily an assured hope and a holy law, as fear of the Judge who can cast into hell and as an inflexible rule of faith and of discipline. Of the glorious liberty of the children of God he had nothing but a mere presentiment; he looked for it only in the world beyond the grave, and under the power of the Gospel he counted as loss all the world could give. He well understood the meaning of Christ's saying that He came not into the world to bring peace, but a sword: in a period when a lax spirit of conformity to the world had seized the churches he maintained the "vigor evangelicus" not merely against the Gnostics but against opportunists and a worldly-wise clergy. Among all the fathers of the first three centuries Tertullian has given the most powerful expression to the terrible earnestness of the Gospel.

(3) The course of Tertullian's personal development fitted him in an altogether remarkable degree to be a teacher of the church. Born at Carthage of good family—his father was a "centurio pro consularis"—he received a first-rate education both in Latin and in Greek. He was able to speak and write Greek, and gives evidence of familiarity alike with its prose and with its poetry; and his excellent memory—though he himself complains about it—enabled him always to bring in at the right place an appropriate, often brilliant, quotation or some historical allusion. The old historians, from Herodotus to Tacitus, were familiar to him, and the accuracy of his historical knowledge is astonishing. He studied with earnest zeal the Greek philosophers; Plato in particular, and the writings of the Stoics, he had fully at command, and his treatise *De Anima* shows that he himself was able to investigate and discuss philosophical problems. From the philosophers he had been led to the medical writers, whose treatises plainly had a place in his working library. But no portion of this rich store of miscellaneous knowledge has left its characteristic impress on his writings; this influence was reserved for his legal training. His father, whose military spirit reveals itself in the whole bearing of Tertullian, to whom Christianity was above everything a "militia," had intended him for the law. He studied in Carthage, probably also in Rome, where, according to Eusebius, he enjoyed the reputation of being one of the most eminent jurists. This statement derives confirmation from the *Digest*, where references are made to two works, *De Castrensi Peculio* and *Quaestionum Libri VIII.*, of a Roman jurist named Tertullian, who must have flourished about 180 A.D. In point of fact the quondam advocate never disappeared in the Christian presbyter. This was at once his strength and his weakness: his strength, for as a professional pleader he had learned how to deal with an adversary according to the rules of the art—to pull to pieces his theses, to reduce him *ad absurdum*, and to show the defects and contradictions of his statements,—and was specially qualified to expose the irregularities in the proceedings taken by the state against the Christians; but it was also his weakness, for it was responsible for his litigiousness, his often doubtful shifts and artifices, his sophisms and *argumentationes ad hominem*, his fallacies and surprises. At Rome in mature manhood Tertullian became a Christian, under what circumstances we do not know, and forthwith he bent himself with all his energy to the study of Scripture and of Christian literature. Not only was he master of the contents of the Bible: he also read carefully the works of Hermas, Justin, Tatian, Miltiades, Melito, Irenaeus, Proculus, Clement, as well as many Gnostic treatises, the writings of Marcion in particular. In apologetics his principal master was Justin, and in theology proper and in the controversy with the Gnostics, Irenaeus. As a thinker he was not original, and even as a theologian he has produced but few schemes of doctrine, except his doctrine of sin. His special gift lay in the power to make what had been traditionally received impressive, to give to it its proper form, and to gain for it new currency. From Rome Tertullian visited Greece and perhaps also Asia Minor; at any rate we know that he had temporary relations with the churches there. He was consequently placed in a position in which he could check the doctrine and practice of the Roman church. Thus equipped with knowledge and experience, he returned to Carthage and there laid the foundation of Latin Christian literature. At first, after his conversion, he wrote Greek, but by and by Latin almost exclusively. The elements of this Christian Latin language may be enumerated as follows:—(i.) it had its origin, not in the literary language of Rome as developed by Cicero, but in the language of the people as we find it in Plautus and Terence; (ii.) it has an African complexion; (iii.) it is strongly influenced by Greek, particularly through the Latin translation of the Septuagint and of the New Testament, besides being sprinkled with a large number of Greek words derived from the Scriptures or from the Greek liturgies; (iv.) it bears the stamp of the Gnostic style and contains also some military expressions; (v.) it owes something to the original creative power of Tertullian. As for his theology, its leading factors were—(i.) the teachings of the apologists; (ii.) the philosophy of the Stoics; (iii.) the rule of faith, interpreted in an anti-Gnostic sense, as he had received it from the Church of Rome; (iv.) the Soteriological theology of Melito and Irenaeus; (v.) the substance of the utterances of the Montanist prophets (in the closing decades of his life). This analysis does not disclose, nor indeed is it possible to discover, what was the determining element for Tertullian; in fact he was under the dominion of more than one ruling principle, and he felt himself bound by several mutually opposing authorities. It was his desire to unite the enthusiasm of primitive Christianity with intelligent thought, the original demands of the Gospel with every letter of the Scriptures and with the practice of the Roman church, the sayings of the Paraclete with the authority of the bishops, the law of the churches with the freedom of the inspired, the rigid discipline of the Montanist with all the utterances of the New Testament and with the arrangements of a church seeking to set itself up within the world. At this task he toiled for years, involved in contradictions which it took all the finished skill of the jurist to conceal from him for a time. At last he felt compelled to break off from the church for which he had lived and fought; but the breach could not clear him from the contradictions in which he found himself entangled. Not only did the great chasm between the old Christianity, to which his soul clung, and the Christianity of the Scriptures as juristically and philosophically interpreted remain unbridged; he also clung fast, in spite of his separation from the Catholic church, to his position that the church possesses the true doctrine, that the bishops *per successionem* are the repositories of the grace of the teaching office, and so forth. The growing violence of his latest works is to be accounted for, not only by his burning indignation against the ever-advancing secularization of the Catholic church, but also by the incompatibility between the authorities which he recognized and yet was not able to reconcile. After having done battle with heathens, Jews, Marcionites, Gnostics, Monarchians, and the Catholics, he died an old man, carrying with him to the grave the last remains of primitive Christianity in the West, but at the same time in conflict with himself.

(4) What has just been said brings out very clearly how important in their bearing on Tertullian's development were the circumstances of the age in which he laboured. His activity

as a Christian falls between 190 and 220, a period of very great moment in the history of the Catholic church; for within it the struggle with Gnosticism was brought to a victorious close, the New Testament established a firm footing within the churches, the "apostolic" rules which thenceforward regulated all the affairs of the church were called into existence, and the ecclesiastical priesthood came to be developed. Within this period also falls that evangelical and legal reaction against the political and secular tendencies of the church which is known as Montanism. The same Tertullian who had fortified the Catholic church against Gnosticism was none the less anxious to protect it from becoming a political organization. Being unable to reconcile incompatibles, he broke with the church and became the most powerful representative of Montanism in the West.

Although Tertullian's extant works are both numerous and copious, our knowledge of his life is very vague. He cannot have been born much later than about 150. His activity as a jurist in Rome must fall within the period of Commodus; for there is no indication in his writings that he was in Rome in the time of Marcus Aurelius, and many passages seem to preclude the supposition. The date of his conversion to Christianity is quite uncertain; there is much in favour of the years between 190 and 195. How long he remained in Rome after becoming a Christian, whether he had attained any office in the church before leaving Rome, what was the date of his visit to Greece—on these points also we remain in ignorance. It is certain that he was settled in Carthage in the second half of 197, the date of his writing his *Apologeticus* and (shortly afterwards) his two books *Ad nationes*; we also know that he became a presbyter in Carthage and was married. His recognition of the Montanistic prophecy in Phrygia as a work of God took place in 202–203, at the time when a new persecution broke out. For the next five years it was his constant endeavour to secure the victory for Montanism within the church; but in this he became involved more and more deeply in controversy with the majority of the church in Carthage and especially with its clergy, which had the support of the clergy of Rome. As Jerome writes (*De vir. ill.* 53): "Usque ad mediam aetatem presbyter fuit ecclesiae Africanae, invidia postea et contumeliis clericorum Romanae ecclesiae ad Montani dogma delapsus." On his breach with the Catholic church, probably in 207–208, he became the head of a small Montanist community in Carthage. In this position he continued to labour, to write, and to assail the lax Catholics and their clergy until at least the time of Bishop Calixtus in the reign of Elagabalus. The year of his death is uncertain. Jerome (*ut sup.*) says: "Fertur vixisse usque ad decrepitam aetatem." That he returned at last to the bosom of the Catholic church is a mere legend, the motive of which is obvious; his adherents after his death continued to maintain themselves as a small community in Carthage. Although he had left the church, his earlier writings continued to be extensively read; and in the 4th century his works, along with those of Cyprian, were the principal reading of Western Christians, until they were superseded by those of Jerome, Ambrose, Augustine and Gregory. Jerome has included him in his catalogue of Christian "viri illustres," but only as a Catholic to whom reference should be made with caution.[1]

The works of Tertullian, on the chronology of which a great deal has been written, and which for the most part do not admit of being dated with perfect certainty, fall into three classes—the apologetic, defending Christianity against paganism and Judaism; the polemical dogmatic, refuting heresies and heretics; and the ascetic or practical, dealing with points of morality and church discipline. In point of time also three periods can be readily distinguished, the years 202–203 and 207–208 constituting the divisions. Some of the books he wrote have unfortunately disappeared—in particular the *De spectaculis*, *De baptismo*, and *De virginibus velandis* in Greek; his works in Latin on the same subjects have survived.

I. *Works dating from before 202–203.*—To this class belong the *Apologeticus* (197) and the two books *Ad nationes*, *De spectaculis*, *De idololatria*, *De cultu feminarum Libri II.*, *De testimonio animae* (written soon after the *Apologeticus*), *Ad martyres* (perhaps the earliest of all), *De baptismo haereticorum* (now lost), *De baptismo*, *De poenitentia*, *De oratione* (the last three written for catechumens), *De patientia*, *Ad uxorem Libri II.*, *De praescriptione haereticorum*, and *Adv. Marcionem* (in its first form). The *Apologeticus*, which in the 3rd century was translated into Greek, is the weightiest work in defence of Christianity of the first two centuries. It disposes of the charges brought against Christians for secret crimes (incest, &c.) and public offences (contempt of the State religion and high treason), and asserts the absolute superiority of Christianity as a revealed religion beyond the rivalry of all human systems.

[1] Compare also the judgment of Hilary and of Vincent of Lerins, *Commonit.*, 24.

Respecting its relation to the *Octavius* of Minucius Felix much has been written; to the present writer it seems unquestionable that Tertullian's work was the later. Of great moment also is the *De praescriptione haereticorum*, in which the jurist is more clearly heard than the Christian. It is the chief of the dogmatic or polemical works, and rules the accuser out of court at the very opening of the case. The *De spectaculis* and *De idololatria* show that Tertullian was already in a certain sense a Montanist before he formally went over to that creed; on the other hand, his *De poenitentia* proves that his earlier views on church discipline were much more tolerant than his later. To learn something of his Christian temper we must read the *De oratione* and the *De patientia*. The *De baptismo* is of special interest from the archaeological point of view.

II. *Works written between 202–203 and 207–208.*—*De virginibus velandis*, *De corona militis*, *De fuga in persecutione*, *De exhortatione castitatis*, *De scorpiace* (a booklet against the Gnostics, whom he compares to scorpions; it is written in praise of martyrdom), *Adversus Hermogenem*, *De censu animae adv. Hermogenem* (lost), *Adv. Valentinianos*, *Adv. Apelleiacos* (lost), *De paradiso* (lost), *De fato* (lost), *De anima* (the first book on Christian psychology), *De carne Christi*, *De resurrectione carnis*, and *De spe fidelium* (lost), were all written after Tertullian had recognized the prophetic claims of the Montanists, but before he had left the church.

III. *Works later than 207–208.*—To this period belong the five books *Adv. Marcionem*, his main anti-Gnostic work (in the third form—the first of the five was written in 207–208), *Ad Scapulam* (an admonition to the persecuting proconsul of Africa, written soon after 212), *De pallio* (a defence of his wearing the pallium instead of the toga), *Adv. Praxean* (his principal work against the Monarchians), and *Adv. Judaeos*, chaps. ix.–xiv. of which are a completion by another and less skilful hand. The latest extant works of Tertullian (all after 217) are his controversial writings against the laxity of the Catholics, full of the bitterest attacks, especially upon Calixtus, the bishop of Rome; these are *De monogamia*, *De jejunio*, *De pudicitia*, and *De ecstasi Libri VII.* (lost). The arguments against the genuineness of some of the above writings do not seem to the present writer to have weight. It is quite possible that Tertullian was the author of the *Acta perpetuae et felicitatis*, but he did not write the *Libellus adv omnes haereses* often appended to *De praescriptione;* or the poems *Adv. Marcionem*, *De Sodoma*, *De Jona*, *De Genesi*, *De judicio Domini;* or the fragment *De execrandis gentium diis;* or the *De Trinitate* and *De cibis Judaicis* of Novatian.

Editions.—For the MSS. see E. Preuschen in A. Harnack, *Geschichte der altchristl. Literatur*, i. 675–7. Of printed collections the chief are the *editio princeps* by Beatus Rhenanus (Basel, 1521), Migne, *Patr. Lat.* i.–ii. (Paris, 1844); Fr. Oehler (3 vols., Leipzig, 1851–4); and A. Reifferscheid and G. Wissowa in the *Corpus scriptorum eccl. Lat.* (Pars i., Vienna, 1890). Editions of the separate books are almost innumerable.

Translations.—German by K. A. H. Kellner (2 vols. Cologne, 1882) and selections in *Bibliothek der Kirchenväter* (1869, 1872); English by S. Thelwall and others in *Ante-Nicene Fathers*, iii. and iv., and (apologetic and practical writings) by C. Dodgson in *Library of the Fathers*, x. (Oxford, 1842).

Literature.—Fr. Oehler's third volume contains a collection of early dissertations. See also A. Hauck, *Tertullian's Leben und Schriften* (Erlangen, 1877); J. M. Fuller in *Dict. Chr. Biog.*, iv. 818–864; E. Nolldechen, *Tertullian* (Gotha, 1890); P. Monceaux, *Histoire littéraire de l'Afrique chrétienne*, vol. i. (Paris, 1901); T. R. Glover, *The Conflict of Religions in the Early Roman Empire*, chap. x. (London, 1909); and the various Histories of Dogma and Church Histories.

For a complete bibliography see G. Krüger, *Hist. of Early Christian Literature* (Eng. tr. New York and London, 1897); Herzog-Hauck, *Realencyk. für prot. Theologie*, xix.; and O. Bardenhewer, *Patrology* (Eng. tr. Freiburg im Breisgau and St Louis, 1908). A large number of earlier monographs on special points are cited in the 9th edn. of the *Ency. Brit.* (A. Ha.; X.)

TERUEL, a province of north-eastern Spain, formed in 1833 from part of the ancient kingdom of Aragon; bounded on the N. by Saragossa, E. by Tarragona, S.E. and S. by Castellon de la Plana and Valencia, S.W. by Cuenca, and W. by Guadalajara. Pop. (1900) 246,001; area 5720 sq. m. In the centre of the province rise the Sierras of Gudar and San Just; in the south-west and west are the lofty Albarracin range, the Montes Universales, and the isolated ridges of Palomera and Cucalon. Outliers of the Castellon and Tarragona highlands extend along the eastern border. The northern districts belong to the Ebro basin. In the west there are a few peaks, such as the Cerro de San Felipe and Muela de San Juan, which exceed 5000 ft. in altitude and are covered with snow for many months; but the highest point is Javalambre (6568 ft.) in the south. The sierras give rise to several large rivers, the principal being the Tagus (*q.v.*); the Guadalaviar, which rises in the Montes Universales and flows south-east to enter the Mediterranean at Valencia; the Jiloca, which flows north from the lake of Cella to join the Jalón at Calatayud; the Guadalope, Martin and Matarraña, tributaries of the Ebro.

Notwithstanding the fertile character of the plains and the abundance of mineral wealth, the trade of the province is unimportant and civilization in a backward state, owing to the lack of means of transport, want of enterprise and imperfect communication with the outer world. Much land is devoted to pasture that could be cultivated. Extensive forests with fine timber are neglected, as are some important coal beds in the eastern districts. The chief products are corn, wine, oil, cheese, fruits, timber, flax, hemp, silk, wool and saffron, together with cattle, sheep and swine; while in the busier centres some slight manufacture of coarse cloth, paper, leather, soap, pottery and esparto goods is carried on. The only railway is the line from Murviedro, on the Gulf of Valencia, to Calatayud.

TERUEL, the capital of the Spanish province of Teruel; on the left bank of the river Guadalaviar, at its confluence with the Alfambra, and on the Murviedro-Calatayud railway. Pop. (1900) 10,797. The older part of Teruel is a walled city with narrow gloomy streets and crumbling medieval houses, but modern suburbs have been built outside the walls. Some of the numerous churches are worth seeing, with their paintings by the 17th-century artist Antonio Visquert. In the cloisters of San Pedro lie the remains of the celebrated "lovers of Teruel," Juan de Marcilla and Isabella de Segura, who lived in the 13th century and whose pathetic story has formed the subject of numerous dramas and poems by Perez de Montalban, Yaquë de Salas, Hartzenbusch and others. The cathedral dates from the 16th century. The great aqueduct of 140 arches was erected in 1555–60 by Pierre Bedel, a French architect. Teruel has several good hospitals and asylums for the aged and children, an institute, a training school for teachers, primary schools, a public library, an athenaeum, a meteorological station, and a large prison. The see was created in 1577, and forms part of the archiepiscopal province of Saragossa.

TERVUEREN, a small town of Belgium in the province of Brabant, midway between Brussels and Louvain. Pop. (1904) 4017. It contained an ancient abbey and a hunting château belonging to the dukes of Brabant. The fine park of Tervueren is really part of the forest of Soignies. The Colonial Museum and World's Colonial School are established here, and Tervueren is connected with Brussels by a fine broad avenue, traversed by an electric tramway as well as by carriage and other roads, and between 6 and 7 m. in length.

TERZA RIMA, or "third rhyme," a form of verse adapted from the Italian poets of the 13th century. Its origin has been attributed by some to the three-lined ritournel, which was an early Italian form of popular poetry, and by others to the sirventes of the Provençal troubadours. The *serventese incatenato* of the latter was an arrangement of triple rhymes, and unquestionably appears to have a relation with terza rima; this connexion becomes almost a certainty when we consider the admiration expressed by the Tuscan poets of the 13th century for the metrical inventions of their forerunners, the Provençals. In Italian, a stanza of terza rima consists of three lines of eleven syllables, linked with the next stanza, and with the next, and so on, by a recurrence of rhymes: thus aba, bcb, cdc, ded, &c., so that, however long the poem is, it can be divided nowhere without severing the continuity of the rhyme. Schuchardt has developed an ingenious theory that these successive terzinas are really chains of ritournels, just as ottava rima, according to the same theory, is a chain of rispetti. There were, unquestionably, chains of interwoven triple rhymed lines before the days of Dante, but it was certainly he who raised terza rima from the category of folk-verse, and gave it artistic character. What this character is may best be seen by an examination of the austere and majestic lines with which the *Inferno* opens, no more perfect example of terza rima having ever been composed:—

"Nel mezzo del cammin di nostra vita
  Mi retrovai per una selva obscura,
Che la diritta via era smarrita.
  Ahi quanto a dir qual'era è cosa dura
Questà selva selvaggia ed aspra e forte,
  Che nel pensier rinnova la paura!"

It is impossible, however, to break off here, since there is no rhyme to *forte*, which has to be supplied twice in the succeeding terzina, where, however, a fresh rhyme, *trovai*, is introduced, linking the whole to a still further terzina, and so on, indefinitely. The only way in which a poem in terza rima can be closed is by abandoning a rhyme, as at the end of Canto I of the *Inferno*, where no third rhyme is supplied to *Pietro* and *dietro*. Boccaccio wrote terza rima in close following of Dante; but it has not been a form very frequently adopted by Italian poets. Nor has the extreme difficulty of sustaining dignity and force in these complicated chains of verse made writers in other languages very anxious to adventure on terza rima. In the age of Elizabeth, Samuel Daniel employed it in his "Epistle to the Countess of Bedford," but he found no followers. Probably the most successfully sustained poem in terza rima in the English language is Mrs Browning's *Casa Guidi Windows* (1851). The Germans have always had an ambition to write in terza rima. It was used by Paul Schede, a writer of whom little is known, before the close of the 16th century, and repeatedly by Martin Opitz (1597–1639), who called the form *drittreime*. Two centuries and a half later, W. Schlegel had the courage to translate Dante in the metre of the Italian; and it was used for original poems by Chamisso and Rückert. Goethe, in 1826, addressed a poem in terza rima to the praise of Schiller, and there is a passage in this metre at the beginning of the second part of *Faust*.

See Hugo Schuchardt, *Ritournell und Terzine* (Halle, 1875).
(E. G.)

TESCHEN (Czech, *Těšin;* Polish, *Cieszyn*), a town of Austria, in Silesia, 50 m. S.E. of Troppau by rail. Pop. (1900) 19,142, of which over half is German, 43 per cent. Polish and the remainder Czech. It is situated on the Olsa, a tributary of the Oder, and combines both Polish and German peculiarities in the style of its buildings. The only relic of the ancient castle is a square tower, dating from the 12th century. There are several furniture factories and large saw-mills.

Teschen is an old town and was the capital of the duchy of Teschen. It was at Teschen that Maria Theresa and Frederick II. signed, in May 1779, the Peace, which put an end to the war of Bavarian succession. The duchy of Teschen belonged to the dukes of Upper Silesia, and since 1298 it stood under the suzerainty of Bohemia. It became a direct apanage of the Bohemian crown in 1625 at the extinction of the male line of its dukes, and since 1766 it bore the name of Saxe-Teschen, owing to the fact that Prince Albert of Saxony, who married a daughter of Maria Theresa, received it as part of his wife's dowry. In 1822, it was bestowed on the Archduke Charles, the victor of Aspern; it was inherited by his eldest son, and, at his death, in 1895 it passed into the hands of his nephew, the Archduke Frederick.

TESSELLATED (Lat. *tessellatus*,), formed of *tessellae*, or small *tesserae*, cubes from half an inch to an inch square like dice, of pottery, stone, marble, enamel, &c. (See PAVEMENT and MOSAIC.)

TESSIN, CARL GUSTAF, COUNT (1695–1770), Swedish statesman, son of a great architect, Nicodemus Tessin, began his public career in 1723, at which time he was a member of the Holstein faction. In 1725 he was appointed ambassador at Vienna, and in that capacity counteracted the plans of the Swedish chancellor, Count Arvid Horn, who was for acceding to the Hanoverian Alliance. During the *riksdags* 1726–27 and 1731 he fiercely opposed the government, and his wit, eloquence and imposing presence made him one of the foremost protagonists of the party subsequently known as "The Hats" (see SWEDEN: *History*). From 1735 to 1736 he was again Swedish ambassador at Vienna. During the *riksdag* of 1738 he was elected marshal of the diet and contributed more than anyone else to overthrow the Horn administration the same year. On the division of the spoil of patronage he chose for himself the post of ambassador extraordinary at Paris, and from 1739 to

1742 delighted Versailles with his brilliant qualities of *grand seigneur*, at the same time renewing the traditional alliance between France and Sweden which had been interrupted for more than sixty years. His political ability, however, was by no means commensurate with his splendid social qualities. It was his sanguine credulity which committed the "Hats" to their rash and unconsidered war with Russia in 1741–42, though in fairness it must be added that Tessin helped them out of their difficulties again by his adroitness as a party leader and his stirring eloquence. He gained his arm-chair in the senate as a reward for his services on this occasion. In 1743 Tessin composed the long outstanding differences between Sweden and Denmark in a special mission to Copenhagen. In 1744 he was sent at the head of an extraordinary embassade to Berlin to escort to Stockholm Frederick the Great's sister, Louisa Ulrica, the chosen bride of the Swedish crown-prince, Adolphus Frederick. As *overhofmarskalk* of the young court, Tessin speedily captivated the royal pair. He also succeeded in withdrawing the crown-prince from beneath the influence of the Russian empress Elizabeth, to whom Adolphus Frederick owed his throne when he became king of Sweden in 1751, thereby essentially contributing to the maintenance of the independence of Sweden. From 1746 to 1752 Tessin was president of the chancellery, as the Swedish prime minister was called in those days. His "system" aimed at a *rapprochement* with Denmark with the view of counterbalancing the influence of Russia in the north. It was a dignified and prudent policy, but his endeavour to consolidate it by promoting a matrimonial alliance between the two courts alienated the Swedish crown-prince, who, as a Holsteiner, nourished an ineradicable hatred of everything Danish. As, moreover, on the accession of Adolphus Frederick in 1751, Tessin refused to countenance any extension of the royal prerogative, the rupture between him and the court became final. On the occasion of the coronation (1752) he resigned the premiership, and in 1754 the governorship of the young crown-prince Gustavus also, spending the rest of his days at his estate at Åkerö. Tessin was one of the most brilliant personages of his day, and the most prominent representative of French culture in Sweden. He was also a fine orator, and his literary style is excellent.

His principal works are his autobiographical fragments (1st ed. Stockholm, 1819), *Tessin och Tessiniana; K. G. Tessin's Dagbok* (Stockholm, 1824), both of them extracts from his voluminous MS. memoirs in 29 volumes; and his famous *En gammal mans bref til en ung Prins* (Stockholm, 1753; English editions, 1755 and 1756), addressed to his pupil, afterwards Gustavus III., one of the most delightful books for the young that ever saw the light.

See R. Nisbet Bain, *Gustavus III. and his Contemporaries* (London, 1895), vol. i; Bernhard von Beskow, *Minne af Grefve K. G. Tessin* (Stockholm, 1864); Bernhard Elis Malmström, *Sveriges politiska historia från Konung Karl XII.'s dod till statshvälfningen*, 1772 (Stockholm, 1893–1901). (R. N. B.)

TEST ACTS. The principle that none but persons professing the established religion were eligible for public employment was adopted by the legislatures of both England and Scotland soon after the Reformation. In England the Acts of Supremacy and Uniformity and the severe penalties denounced against recusants, whether Roman Catholic or Nonconformist, were affirmations of this principle. The Act of 7 Jac. I. c. 2 provided that all such as were naturalized or restored in blood should receive the sacrament of the Lord's Supper. It was not, however, until the reign of Charles II. that actual receiving of the communion of the Church of England was made a condition precedent to the holding of public offices. The earliest imposition of this test was by the Corporation Act of 1661 (13 Car. II. st. 2, c. 1), enacting that, besides taking the oath of allegiance and supremacy and subscribing a declaration against the Solemn League and Covenant, all members of corporations were within one year after election to receive the sacrament of the Lord's Supper according to the rites of the Church of England. This act was followed by the Test Act of 1672 (25 Car. II. c. 2). The immediate cause of the Test Act (the full title of which is "An act for preventing dangers which may happen from popish recusants") was the king's declaration of indulgence, dispensing with laws inflicting disabilities on Nonconformists. This act enforced upon all persons filling any office, civil or military, the obligation of taking the oaths of supremacy and allegiance and subscribing a declaration against transubstantiation, and also of receiving the sacrament within three months after admittance to office. The act did not extend to peers; but in 1678 30 Car. II. st. 2 enacted that all peers and members of the House of Commons should make a declaration against transubstantiation, invocation of saints, and the sacrifice of the mass—a special exception being made in favour of the duke of York. The provisions of the Test Act were violated by both Charles II. and James II. on the ground of the dispensing power claimed by the Stuart kings. In the well-known case of *Godden* v. *Hales* (11 State Trials, 1166), an action for penalties under the Test Act brought against an officer in the army, the judges decided in favour of the dispensing power—a power finally abolished by the Bill of Rights. After a considerable number of amendments and partial repeals by the legislature of the acts of 1661, 1672 and 1678, and of acts of indemnity to protect persons under certain circumstances from penalties incurred under the Test Act, the necessity of receiving the sacrament as a qualification for office was abolished by 9 Geo. IV. c. 17, and all acts requiring the taking of oaths and declarations against transubstantiation, &c., were repealed by the Roman Catholic Relief Act of 1829 (10 Geo. IV. c. 7). This general repeal has been followed by the special repeal of the Corporation Act by the Promissory Oaths Act 1871, of the Test Act by the Statute Law Revision Act 1863, and of the act of 1678 by an act of 1866 (29 & 30 Vict. c. 19). Religious tests remained in the English universities until 1871, in Dublin University until 1873, and the Scottish universities until 1889. To be a member of the Church of England was a necessary condition precedent for holding most university or college offices by the Act of Uniformity of 1662, and such offices were not affected by the Toleration Act of 1688 and the Roman Catholic Relief Act of 1829. In 1871 the University Tests Act abolished subscriptions to the articles of the Church of England, all declarations and oaths respecting religious belief, and all compulsory attendance at public worship in the universities of Oxford, Cambridge and Durham. There is an exception confining to persons in holy orders of the Church of England degrees in divinity and positions restricted to persons in holy orders, such as the divinity and Hebrew professorships.

Scotland.—A religious test was imposed immediately after the Reformation. By 1567, c. 9, no one was to be appointed to a public office or to be a notary who did not profess the Reformed religion. The Scottish Test Act was 1681, c. 6, rescinded by 1690, c. 7. Renunciation of popery was to be made by persons employed in education (1700, c. 3). A motion to add, after the 18th article of union, an exemption of Scotsmen from the sacramental test in the United Kingdom was negatived by the Scottish parliament. A similar fate awaited a proposal that while a sacramental test was in force in England all persons in public office in Scotland should subscribe their adhesion to the Presbyterian Church government. By 1707, c. 6, all professors, principals, regents, masters or others bearing office in any university, college or school in Scotland were to profess and subscribe to the Confession of Faith. All persons were to be free of any oath or test contrary to or inconsistent with the Protestant religion and Presbyterian Church government. The reception of the communion was never a part of the test in Scotland as in England and Ireland. The necessity for subscription to the Confession of Faith by persons holding a university office (other than that of principal or professor of theology) was removed by 16 & 17 Vict. c. 89. The act provided that in place of subscription every person appointed to a university office was to subscribe a declaration according to the form in the act, promising not to teach any opinions opposed to the divine authority of Scripture or to the Confession of Faith, and to do nothing to the prejudice of the Church of Scotland or its doctrines and privileges. All tests were finally abolished by an act of 1889 (52 & 53 Vict. c. 55).

Ireland.—An oath of allegiance was required by the Irish Act of Supremacy (2 Eliz. c. 1). The English Act of 3 Will. & M. c. 2 substituted other oaths and enforced in addition from peers, members of the House of Commons, bishops, barristers, attorneys and others a declaration against transubstantiation, invocation of the Virgin Mary and the saints, and the sacrifice of the mass. By the Irish Act of 2 Anne, c. 6, every person admitted to any office, civil or military, was to take and subscribe the oaths of allegiance, supremacy, and abjuration, to subscribe the declaration against transubstantiation, &c., and to receive the Lord's Supper according to the usage of the Church of Ireland. English legislation on the subject of oaths and declarations was adopted in Ireland by Yelverton's Act, 21 & 22 Geo. III. c. 48, § 3 (Ir.). These provisions were all repealed by the Promissory Oaths Act 1871. The Roman Catholic Relief Act of 1793 (33 Geo. III. c. 21, Ir.) excepted Trinity College, Dublin, from its provisions, and tests existed in Dublin university until 1873. They were abolished as far as regarded certain scientific professorships in 1867 by 30 Vict. c. 9, and were finally abolished for the whole university by the University of Dublin Tests Act 1873, except as to professors of and lecturers in divinity.

United States.—By art. 6 of the constitution, "no religious test shall ever be required as a qualification to any office or public trust under the United States." A similar provision is generally included in the state constitutions.

TESTAMENTS OF THE THREE PATRIARCHS. This apocryphal work of the Hebrew Scriptures was first published by M. R. James (*The Testament of Abraham, the Greek Text now first edited with an Introduction and Notes. With an appendix containing extracts from the Arabic Version of the Testaments of Abraham, Isaac and Jacob, by Barnes, Texts and Studies*, ii. 2: Cambridge). The Greek testament of Abraham is preserved in two recensions from six and three MSS. respectively. This testament is also edited by Vassiliev in his *Anecdota Graeco-Byzantina*, 1893, i. 292–308 from a Vienna MS. already used by James. According to James, it was written in Egypt in the 2nd century A.D., and was translated subsequently into Slavonic (Tichonrawow, *Pamjatniki otretschennoi russkoi Literaturi*, 1863, i. 79–90), Rumanian (Gaster, *Proceedings of the Society of Biblical Archaeology*, 1887, ix. 195–226), Ethiopic and Arabic.

This testament deals with Abraham's reluctance to die and the means by which his death was brought about. As regards its origin James writes (*op. cit.*, p. 55): "The Testament was originally put together in the second century by a Jewish Christian: for the narrative portions he employed existing Jewish legends, and for the apocalyptic, he drew largely on his imagination." He holds that the book is referred to by Origen, *Hom. in Luc.* xxxv. With the exception of x.–xi. the work is really a legend and not an apocalypse.

To the above conclusions Schürer, *Gesch. des jüd. Volkes*, 3rd ed., iii. 252, takes objection. He denies the reference in Origen, and asserts that there are no grounds for the assumption of a partial Jewish origin. But the present writer cannot agree with Schürer in these criticisms, but is convinced that a large body of Jewish tradition lies behind the book. Indeed, Kohler (*Jewish Quarterly Review*, 1895, v. 581–606) has given adequate grounds for regarding this apocryph as in the main an independent work of Jewish origin subsequently enlarged by a few Christian additions.

An English translation of James's texts will be found in the *Ante-Nicene Christian Library* (Clark, 1897), pp. 185–201. The testaments of Isaac and Jacob are in part still preserved in Arabic and Ethiopic (see James, *op. cit.*, 140–161). (R. H. C.)

TESTAMENTS OF THE TWELVE PATRIARCHS. The Testaments of the Twelve Patriarchs (see APOCALYPTIC LITERATURE: *II. Old Testament*), are an important constituent of the apocryphal scriptures connected with the Old Testament, comprising the dying commands of the twelve sons of Jacob.

They "were written in Hebrew in the later years of John Hyrcanus—in all probability after his final victory over the Syrian power and before his breach with the Pharisees—in other words, between 109 and 106. Their author was a Pharisee who combined loyalty to the best traditions of his party with the most unbounded admiration of Hyrcanus. The Maccabean dynasty had now reached the zenith of its prosperity, and in its reigning representative, who alone in the history of Judaism possessed the triple offices of prophet, priest and king, the Pharisaic party had come to recognize the actual Messiah. To this John Hyrcanus, in whom had culminated all the glories and gifts of this great family, our author addresses two Messianic hymns. The writer already sees the Messianic kingdom established, under the sway of which the Gentiles will in due course be saved, Beliar overthrown, sin disappear from the earth, and the righteous dead rise to share in the blessedness of the living. Alas for the vanity of man's judgment and man's prescience! Our book had hardly been published, when Hyrcanus, owing to an injury done him by the Pharisees, broke with their party, and, joining the Sadducees, died a year or two later. His successors proved themselves the basest of men. Their infamy is painted in lurid colours by contemporary writers of the 1st century B.C., and by a strange irony the work, or, rather, fragments of the work of one of these assailants of the later Maccabees, has achieved immortality by finding a covert in the chief manifesto that was issued on behalf of one of the earlier members of that dynasty. This second writer singles out three of the Maccabean priest kings for attack, the first of whom he charges with every abomination; the people itself, he declares, is apostate, and chastisement will follow speedily—the temple will be laid waste, the nation carried afresh into captivity, whence, on their repentance, God will restore them again to their own land, where they shall enjoy the blessedness of God's presence and be ruled by a Messiah sprung from Judah. When we contrast the expectations of the original writer and the actual events that followed, it would seem that the chief value of his work would consist in the light that it throws on this obscure and temporary revolution in the Messianic expectations of Judaism towards the close of the 2nd century. But this is not so. The main, the overwhelming value of the book lies not in this province, but in its ethical teaching, which has achieved a real immortality by influencing the thought and diction of the writers of the New Testament, and even those of our Lord. This ethical teaching, which is indefinitely higher and purer than that of the Old Testament, is yet its true spiritual child, and helps to bridge the chasm that divides the ethics of the Old and New Testaments."[1]

In the early decades of the Christian era the text was current in two forms, which are denoted by H^{α} and H^{β} in this article and in the edition of the text published by the Oxford University Press. "The former of these was translated not later than A.D. 50 into Greek, and this translation was used by the scholar who rendered the second Hebrew recension into Greek. The first Greek translation was used by our Lord, by St Paul, and other New Testament writers. In the second and following centuries it was interpolated by Christian scribes, and finally condemned undiscriminatingly along with other apocryphs. For several centuries it was wholly lost sight of, and it was not till the 13th century that it was rediscovered through the agency of Robert Grosseteste, bishop of Lincoln, who translated it into Latin, under the misconception that it was a genuine work of the twelve sons of Jacob, and that the Christian interpolations were a genuine product of Jewish prophecy. The advent of the Reformation brought in critical methods, and the book was unjustly disparaged as a mere Christian forgery for nearly four centuries. The time has at last arrived for this book, so noble in its ethical side, to come into its own."[2]

Versions and MSS.—The two recensions[3] of the Hebrew original, to which we have already referred, were translated into Greek, the former being attested by the Greek MSS. *chi* and the latter by *a b d e f g*, which groups for the sake of brevity we designate as α and β. The Greek version was in turn rendered into Armenian in the 5th or 6th century. The rendering was made, except in a limited number of passages, from β. Of this version there are at least eleven MSS. known. Here again two types of text, A^{α} and A^{β}, are represented, but for the most part the differences originated within the Armenian. Finally about the 13th century the Slavonic Version was made from the β form of the Greek Version. Here

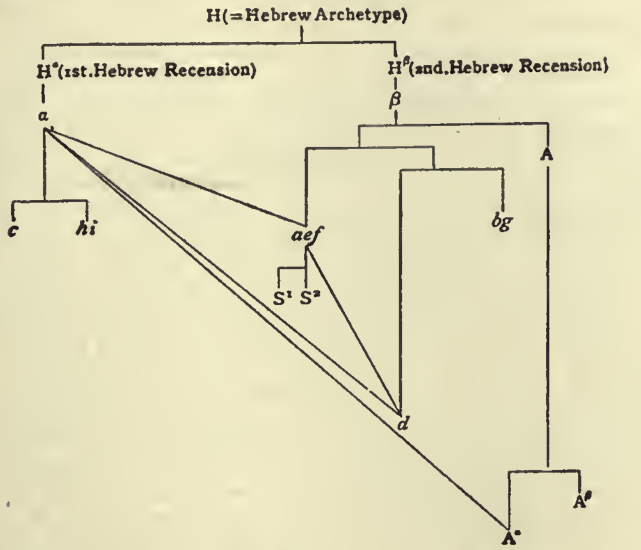
[1] From § 1 of the Introduction to R. H. Charles's *The Testaments of the Twelve Patriarchs, translated from the Editor's Greek Text* (A. & C. Black, 1908).

[2] From § 1 of the Introduction to R. H. Charles's *The Greek Versions of the Testament of the XII. Patriarchs* (Oxford University Press, 1908).

[3] Some of the evidence for this conclusion will be given later.

again we have two recensions S[1] and S[2], but the one may be on the whole reasonably described as an abbreviation of the other.

The relations of the above authorities are too complicated to be treated of here in detail, but they are represented on the subjoined diagram.



Original Language.—Apart from Grabe, till within the last fifteen years no notable scholar has advocated a Hebrew original. Nitzsch, Dillmann, Ritschl and Sinker are convinced that the book was not a translation but was written originally in Greek. To Kohler and Gaster belongs the honour of re-opening the question of the Hebrew original of the Testaments. Only the latter, however, offered any linguistic evidence. In his article[1] on the question he sought to establish a Hebrew original of all the Testaments and to prove that the Hebrew text of Naphtali which he had discovered was the original testament, and that the Greek Naphtali was a late and corrupt reproduction of it with extensive additions from other sources. But he failed in establishing either thesis. The subject was next taken in hand by R. H. Charles, who in a preliminary form in the *Encyclopaedia Biblica* (i. 241, 1899), and later, with considerable fullness, in his edition of the Greek text of the Testaments (1908), brought to light a number of facts that put the question of a Hebrew original beyond the range of doubt. We will now place a few of the grounds before the reader.

(*a*) *Hebrew constructions and expressions are to be found in every page. Though the vocabulary is Greek the idiom is frequently Hebraic and foreign to the genius of the Greek language.* Thus in T. Reub. vi. 11, ἐν αὐτῷ ἐξελέξατο = בו בחר. In T. Jud. xx. 4, ἐν στήθει ὀστέων αὐτοῦ—an utterly unmeaning phrase—becomes intelligible on retroversion—בלב עצמו, "on his very heart." In T. Benj. x. 11 κατοικήσετε ἐπ' ἐλπίδι ἐν ἐμοί = "ye shall dwell *securely* with me"; for here ἐπ' ἐλπίδι, as several times in the Septuagint, is a wrong rendering of לבטח.

(*b*) *Dittographic renderings in the Greek of the same Hebrew expression; also dittographic expressions in the Greek implying dittographs in the Hebrew.* See Introduction to R. H. Charles's Text, § 11.

(*c*) *Paronomasiae which are lost in the Greek can be restored by retranslation into Hebrew.* There are over a dozen of such instances.

(*d*) *Many passages which are obscure or wholly unintelligible in the Greek become clear on retranslation into Hebrew.* Of the large body of such passages (see *op. cit.* § 12) we will give only one. In T. Jud. ix. 3, we have the following impossible sentence, where Esau is referred to: ἤρθη νεκρὸς ἐν ὄρει Σιείρ, καὶ πορευόμενος ἐν Ἀνουίραμ ἀπέθανεν. Here a fragment of the Hebrew original, which has happily been preserved, reads נחלה, "wounded," where the Greek has νεκρὸς = נבלה, which is manifestly a corruption of the former.

In all the above cases there is no divergence among the MSS. and Versions. Yet the restorations are so many and so obvious that our contention might be taken for proven. But there is stronger evidence still, and this is to be found where the MSS. and Versions attest different texts, α standing generally in opposition to β, A (=Armenian Version), and S (=Slavonic Version). By means of this evidence we are able to prove not only that our book is from a Hebrew original, but that also the Hebrew existed in two recensions, H$^\alpha$ and H$^\beta$, which are the parents respectively of α and β (see diagram above).

[1] "The Hebrew Text of one of the Testaments of the XII. Patriarchs" (*Proceedings of the Soc. of Bibl. Archaeology*, December 1893, January 1894).

α and β are not, strictly speaking, Greek recensions; for their chief variations go back to diverse forms of text already existing in the Hebrew H$^\alpha$ and H$^\beta$. For the considerable body of evidence supporting this conclusion see the Introduction to R. H. Charles's Text, § 12. A couple of the many passages in which the variations in α and β are due to variations in H$^\alpha$ and H$^\beta$ will now be given. In T. Benj. xii. 2 α reads ἐκοιμήθη ὕπνῳ καλῷ and β A S[1] ἀπέθανε . . . ἐν γήρει καλῷ. Here ἐκοιμήθη and ἀπέθανε may be taken as renderings of the same Hebrew word, but ὕπνῳ καλῷ = בשינה טובה, an undoubted corruption of בשיבה טובה = "at a good old age." The same corruption invaded both Hebrew recensions in T. Zeb. x. 6; T. Dan. vii. 1; T. Ash. viii. 1; T. Jos. xx. 4, whereas in T. Iss. vii. 9 both recensions were right. In the late Hebrew text of Naph. i. 1 the correct Hebrew phrase is found. Again in T. Ash. vi. 6 α reads εἰσφέρει αὐτὸν εἰς ζωὴν αἰώνιον and β A S[1] παραμυθεῖται αὐτὸν ἐν ζωῇ. Here παραμυθεῖται = ינחם, a corruption of ינחה = εἰσφέρει. It is the soul of the righteous that is here spoken of, and α rightly says that the angel of peace "leads him into eternal life." The rightness of H$^\alpha$ is confirmed by T. Benj. vi. 1, which reads ὁ γὰρ ἄγγελος τῆς εἰρήνης ὁδηγεῖ τὴν ψυχὴν αὐτοῦ.

H$^\alpha$ and H$^\beta$, however, differed mainly from each other in words and phrases, as we infer from α and β. In some passages, however, the divergence is on a larger scale, as in T. Lev. ii. 7–iii. Notwithstanding these divergences, however, the great similarities between α and β oblige us to assume that the translator of H$^\beta$ used the Greek version of H$^\alpha$, or vice versa. That the former is the more likely we shall see presently. To the above we have a good parallel in the Book of Daniel; for the variations of its two chief Greek Versions—that of the Septuagint and of Theodotion—go back to variations in the Semitic.

Date of the Original Hebrew.—"The date of the groundwork of the Testaments is not difficult to determine. Thus Reuben (T. Reub. vi. 10–11) admonishes his sons: Πρὸς τὸν Λευὶ ἐγγίσατε ἐν ταπεινώσει καρδίας ὑμῶν ἵνα δέξησθε εὐλογίαν ἐκ τοῦ στόματος αὐτοῦ . . . ὅτι ἐν αὐτῷ ἐξελέξατο Κύριος βασιλεύειν ἐνώπιον παντὸς τοῦ λαοῦ. Here a high-priest who is also a king is referred to. Such a combination of offices naturally makes us think of the Maccabean priest-kings of the 2nd century B.C. The possibility of doubting this reference is excluded by the words that immediately follow:—καὶ προσκυνήσατε τὸ σπέρμα αὐτοῦ ὅτι ὑπὲρ ὑμῶν ἀποθανεῖται ἐν πολέμοις ὁρατοῖς καὶ ἀοράτοις· καὶ ἐν ὑμῖν ἔσται βασιλεὺς αἰώνιος. A similar statement is made in T. Sim. v. 5. Thus the high-priest is not only a high-priest and civil ruler, but also a warrior. That the Maccabean high-priests are here designed cannot be reasonably doubted. But the identification becomes undeniable, as further characteristics of this priestly dynasty come to light. It was to be a new priesthood and to be called by a new name (T. Lev. viii. 14 ἱερατείαν νέαν . . . ὄνομα καινόν). Now the Maccabean high-priests were the first to assume the title 'priests of the Most High God'—the title anciently borne by Melchizedek. But the praises accorded in this book could not apply to all the Maccabean priest-kings of the nation. As it was written by a Pharisee, it could not have been composed after the breach arose between John Hyrcanus and the Pharisees towards the close of the 2nd century B.C. Thus the period of composition lies between 153, when Jonathan the Maccabee assumed the high-priesthood, and the year of the breach of John Hyrcanus with the Pharisees; some time, therefore, between 153 and 107. But the date can be determined between closer limits. To one member of the Maccabean dynasty are the prophetic gifts assigned in our text (T. Lev. viii. 15) in conjunction with the functions of kingship and priesthood. Now, in all Jewish history the triple offices were ascribed to only one individual, John Hyrcanus. Hence we conclude that the Testaments were written between 137 and 107." But the limits of the date of composition be fixed still more definitely. For the text refers most probably to the destruction of Samaria, T. Lev. vi. 11. In that case the Testaments were written between 109 and 107 B.C.

Date of the Greek Version.—The α Version seems to have been translated first, indeed before A.D. 50; for it is twice quoted by St Paul. The first passage is in Rom. i. 32 οὐ μόνον αὐτὰ ποιοῦσιν ἀλλὰ καὶ συνευδοκοῦσιν τοῖς πράσσουσιν which is taken almost verbally from T. Ash. vi. 2, ὅτι οἱ διπρόσωποι δισσῶς †κολάσονται (*rd.* ἁμαρτάνουσι) ὅτι καὶ πράσσουσι τὸ κακὸν καὶ συνευδοκοῦσι τοῖς πράσσουσιν. Since *bg*, A omit the words ὅτι . . . πράσσουσιν, we conclude that, though it is now found in α, *adef*, S[1], it was originally wanting in β and probably also in H$_\beta$. For as we have already seen (see diagram above) *aef* were early influenced by α, and *d* is conflate in character. Hence in reality the passage was preserved only by α originally.

The second passage is the well-known one in 1 Thess. ii. 16, ἔφθασεν δὲ ἐπ' αὐτοὺς ἡ ὀργὴ (+τοῦ θεοῦ DEFG *it*, Vulg. *go*) εἰς τέλος, which is borrowed from T. Lev. vi. 11, ἔφθασεν δὲ (+ἐπ' β) αὐτοὺς ἡ ὀργὴ τοῦ θεοῦ εἰς τέλος.

Here β reads Κυρίου for τοῦ θεοῦ. The ἐπὶ is omitted by α through a simple scribal error.

On the ground of the above quotations we assume, therefore, that α was used by St Paul, and that H$^\alpha$ was therefore translated into Greek at latest before A.D. 50.

When H^{β} was translated we have no definite means of determining. It was in all likelihood done subsequently to H^{α}. The translator of H^{β} appears to have had the translation of H^{α} before him, and to have followed it generally unless where there were manifest divergencies between H^{α} and H^{β}.[1]

Jewish Additions to the Text.—(*a*) A large body of these additions can be classed under one head as written with a well-defined object and at a definite period. This period was about 70–40 B.C., and the object of the additions was the overthrow of the Maccabean high-priesthood, which in the 1st century B.C. had become guilty of every lewdness. T. Lev. x., xiv.–xvi.; T. Jud. xvii. 2–xviii. 1 (?), xxi. 6–xxiii., xxiv. 4–6; T. Zeb. ix.; T. Dan. v. 6–7, vii. 3 (?); T. Naph. iv.; T. Gad. viii. 2; T. Ash. vii. 4–7. These additions are identical in object and closely related in character and diction with the Psalms of Solomon.

(*b*) Other additions are of various dates and cannot be more than mentioned here, *i.e.*, T. Reub. ii. 3–iii. 2; T. Lev. xvii. 1–9; T. Zeb. vi. 4–6, vii.–viii. 3; T. Jos. x. 5–xviii.

Christian Additions to the Text.—These additions are to be found in most of the Testaments and were made at different periods. The existence of these Christian elements in the text misled nearly every scholar for the past four hundred years into believing that the book itself was a Christian apocryph. To Grabe, Schnapp and Conybeare belongs the credit of showing that the Christian elements were interpolations—to Conybeare especially of the three, since, whereas the two others showed the high probability of their contention on internal evidence, Conybeare proved by means of the Armenian Version that when it was made many of the interpolations had not yet found their way into the text. For a full treatment of these passages see R. H. Charles's *Testaments of the Twelve Patriarchs* (1908), Introd. § 20.

Influence on the New Testament.—We have already shown that St Paul twice quoted from the Greek text of the Testaments. These two passages in Rom. and 1 Thess. give but the very faintest idea of the degree of his indebtedness in thought and phraseology in several of his Epistles, especially that to the Romans. But of still greater interest are the passages in the Gospels which show the influence of the Testaments, and these belong mainly to the sayings and discourses of our Lord. We may mention two of the most notable of these. Thus Matt. xviii. 15, 35, which deal with the great question of forgiveness, are clearly dependent on our text.

Matt. xviii. 15. Ἐὰν δὲ ἁμαρτήσῃ ὁ ἀδελφός σου κατά σου, ὕπαγε ἔλεγξον αὐτὸν μεταξὺ σοῦ καὶ αὐτοῦ μόνου.	T. Gad. vi. 3. Ἐάν τις ἁμαρτήσει εἰς σέ εἰπὲ αὐτῷ ἐν εἰρήνῃ . . . καὶ ἐὰν . . . μετανοήσῃ ἄφες αὐτῷ.
35. Ἐὰν μὴ ἀφῆτε ἕκαστος τῷ ἀδελφῷ αὐτοῦ ἀπὸ τῶν καρδιῶν ὑμῶν.	vi. 6. Ἡσύχασον μὴ ἐλέγξῃς. . . .
	v. 7. Ἄφες αὐτῷ ἀπὸ καρδίας.

Next, the duty of loving God and our neighbour is already found in T. Dan. v. 3, which is the oldest literary authority which enjoins these two great commands. The form is infinitely finer in Matt. xxii. 37–39, but the matter is already in the Test. Dan. See Introd. § 26 to R. H. Charles's *Testaments of the Twelve Patriarchs.*

LITERATURE.—(*a*) *Texts.*—Sinker, *Testamenta XII Patriarcharum* (1869); [this work gives *b* in the text and *a* in the footnotes; subsequently (1879) Sinker issued an Appendix with variations from *cg*]; Charles, *The Greek Versions of the Testaments of the XII. Patriarchs from nine MSS., with the Variants from the Armenian and Slavonic Versions and the Hebrew Fragments* (1908). *Commentary.*—Charles, *The Testaments of the Twelve Patriarchs translated from the Editor's Greek Text* (1908). *Critical Inquiries.*—See Schürer, *G. J. V.* iii. 261–262: Charles, *The Test. XII. Patriarchs,* pp. xxxvi.–xli.

(R. H. C.)

TESTAMENTUM DOMINI ("TESTAMENT OF OUR LORD"). Extracts from the book which bears this title, contained in an 8th-century MS. at Paris, were published by Lagarde in 1856 (*Reliquiae iuris ecclesiastici antiquissimae 80–89*); and a Latin fragment, edited by Dr Montague James, appeared in 1893 (*Texts and Studies*, i. 154). The whole book was first published in Syriac in 1899, with a Latin translation by Mgr Rahmani, the Uniat Syrian Patriarch of Antioch. His text is that of a 17th-century MS. at Mosul, the colophon of which says that the Syriac text was translated from the original Greek "*a Jacobo paupere,*" evidently James of Edessa, in A.D. 687; but he makes use of other material, including an Arabic version made from a Coptic copy written in A.D. 927. The Mosul MS. contains the whole Bible in the Peshitto version, followed by the Syrian "Clementine Octateuch," *i.e.*, the collection of ecclesiastical law, in eight books, which was used by the Nestorians and Jacobites. Of this the *Testament* forms the first two books; and according to the title (which, apparently by an error, is made to apply to the whole eight books) it contains the "testament, or words which Our Lord spake to His holy Apostles when He rose from the dead." Plainly, it is one of that series of writings, claiming to embody the fundamental rules of the Church, which culminates in the Apostolical Constitutions (*q.v.*).

It falls into three distinct parts: an apocalyptic introduction (book i. chapters 1–18; the division into books, however, is clearly not original); a "church order" proper (i. 19–ii. 24); and a conclusion (ii. 25–27) of the same apocalyptic character as the introduction. (*a*) The *Introduction* professes to contain the record of the revelation of Himself by the Lord to His Apostles, with whom are Martha, Mary and Salome, on the evening after His resurrection. He is represented as unfolding to them, at their request, the signs of the end, and giving them instruction on various other topics. Incidentally, the fact becomes plain that this section is composed from the standpoint of Asia Minor and Syria, that it dates from soon after the time of Maximin (235–38) and Decius (249–51), and that it springs from a Christian community of a strictly puritan type. (*b*) The *Church Order* follows the general lines of the Canons of Hippolytus and similar documents. It describes the Church and its buildings (i. 19); the office of the bishop and his functions (i. 19–27); the mystagogic instruction (i. 28) common to this and the Arabic Didascalia, where it occurs in an earlier form, and based in part upon the Gnostic "Acts of Peter"; the presbyter (i. 29–32); the deacon (i. 33–38); confessors (i. 39); the "widows who have precedence in sitting" (i. 40–43), apparently the same persons who are spoken of elsewhere as "presbyteresses" (i. 35, ii. 19); the subdeacon (i. 44) and the reader (i. 45), the order of whose offices seems to have been inverted; virgins of both sexes (i. 46); and those who possess *charismata* or spiritual gifts (i. 47). Next come the regulations for the laity, including the whole course of preparation for and admission to baptism (ii. 1–8), confirmation (ii. 9), and the eucharist (ii. 10); after which there follows a series of miscellaneous regulations for Easter and Pentecost (ii. 11–12), the agape (ii. 13), the funds of the Church (ii. 17–20), the visitation of the sick (ii. 21), the use of psalmody (ii. 22), the burial of the dead (ii. 23), and the hours of prayer (ii. 24). (*c*) The *Conclusion* (ii. 25–27) brings us back to the injunctions of the Lord as to the keeping of these precepts, a special charge to John, Andrew and Peter, and a statement that copies of the Testament were made by John, Peter and Matthew, and sent to Jerusalem by the hands of Dositheaus, Sillas, Magnus and Aquila.

In all this there is much that is peculiar to or characteristic of the *Testament*. First and foremost is its ascription to the Lord Himself, which we can hardly be mistaken in regarding as an attempt to claim yet higher sanction than was claimed by the various compilations which were styled "apostolic." This fact alone would lead us to infer the pre-existence of certain of the latter. Again, the whole tone of the *Testamentum* is one of highly strung asceticism, and the regulations are such as point by their severity to a small and strictly organized body. They are "the wise," "the perfect," "sons of light"; but this somewhat Gnostic phraseology is not accompanied with any signs of Gnostic doctrine, and the work as a whole is orthodox in tone. They are set in the midst of "wolves," despised and slighted by the careless and worldly: there is frequent mention of "the persecuted," and of the duty of "bearing the cross." There appears to be no *locus poenitentiae* for serious sins excepting in the case of catechumens, and there is a notable "perfectionist" tone in many of the prayers. *Charismata*, and above all exorcisms, occupy a very important place: there is a vivid realization of the ministry of angels, and the angelic hierarchy is very complete. Great stress is laid upon virginity (although there is not a sign of monasticism), upon fasting (especially for the bishop), upon the regular attendance of the whole clerical body and the "more perfect" of the laity at the hours of prayer. The church buildings are very elaborate, and the baptistery is oblong, a form found apparently only here and in the Arabic Didascalia. Amongst the festivals mentioned are the Epiphany, Easter and Pentecost. With regard to the prayers, they are based upon forms common to this and other Church orders, but have many lengthy interpolations of an inflated and rhapsodic kind. The bishop appears to rank far above the presbyters (more conspicuously so, for example, than in the Canons of Hippolytus), and the presbyters are still divided into two classes, those who are more learned and those

[1] § 14 of the Introduction to R. H. Charles's *The Greek Versions of the Testaments of the XII. Patriarchs.*

who are of mature age. The deacons have functions in the Eucharist and about the altar which point to an early date; they have also much administrative work of an important kind, and especial provisions are made for the care of the sick and the dead, and the burial of those who perish by shipwreck. One of the deacons is to be chosen as "chief deacon" (*protodiaconus*, i. 19, *cf*. i. 34), and is charged with the care of pilgrims. There are no doorkeepers or singers, who begin to appear *circ*. A.D. 340. The honour given to confessors is very conspicuous, and points back to an early date. But remarkable above all is the position given to women. We have "widows having precedence" or presbyteresses, three in number, deaconesses, virgins, and widows who are in receipt of the alms of the Church; and the first-named occupy a place of very great dignity, which is almost unequalled elsewhere (excepting in the earlier form of the apocryphal and Montanistic *Acts and Martyrdom of Matthew*, where the relation of the πρεσβῦτι and deaconess corresponds with that of the *Testament*), and which was formally condemned by the Council of Laodicea in Phrygia.

What conclusion is to be drawn, then, as to the age and character of the *Testament?* Mgr Rahmani's view, that it is a work of the 2nd century, is universally discredited; nor has Funk's contention found acceptance, that it and the Canons of Hippolytus are alike derived ultimately from the eighth book of the *Apostolic Constitutions*. Some scholars think that the Apocalypse at the beginning is pre-Nicene (A.D. 250–325), and that it originates from Asia Minor, probably from Montanistic circles. Harnack formerly contended that this was an independent work, upon which the Church Order had been grafted, and that as a whole it dated from *circ*. A.D. 400. But the unity of thought and atmosphere is such as to show that the work is one whole (subject no doubt to a certain amount of redaction and interpolation), and that the apocalyptic part was composed as an introduction to the rest. As to the central portion (i. 19–ii. 24) it is a Church Order of the same kind as the Canons of Hippolytus (*c*. 220) and the Egyptian (*c*. 310) and Ethiopic (*c*. 335) Church Orders, standing nearer to the two latter than to the former, and especially to the Verona Latin Fragments, part iii. (*c*. 340), published in 1900 by Dr Hauler. The precise relation in which these documents stand to one another still remains in a measure doubtful, but it seems probable that they are based upon a lost Church Order, to which the Canons of Hippolytus stands nearest. [The Greek original of the *Testamentum* would seem to date from the middle of the 4th century, not long after 350. This is the view of T. Zahn and Dom Morin and also of Profs. Cooper and Maclean. It is possible that about 400 a later editor added a few paragraphs.]

Such redaction was indeed inevitable in the case of a work which has had a living history as part of a codex of Church law. It may be discerned in the interpolations in the prayers; possibly in the reference to the chief deacon, for elsewhere no single deacon is distinguished *by name* until the close of the 4th century; in the reference to the Epiphany, which is first heard of elsewhere at the beginning of the 4th century. The suggestion has been hazarded that this revision was due to the school of Apollinaris of Laodicea (died *circ*. A.D. 390).

TESTAMUR, Latin for "we testify" or "certify" (*testari*). The name given in English universities to a certificate given to a student signifying that he has passed an examination, so called from the word with which the certificate begins.

TESTER (Fr. *têtière*, head-covering, from *tête*), anything placed horizontally over the head, as the sound-board of a pulpit, the flat boards over an old-fashioned bed, &c.

TETANUS (from Gr. τείνω, I stretch, on account of the tension of the fibres of the affected muscles), or LOCKJAW, a disease caused by the bacilli Tetani (see PARASITIC DISEASES). The home of these bacilli is the earth, and so it comes about that if a man is thrown off his bicycle and grazes his ungloved hand upon the road, or running without shoes cuts his foot, there is a considerable chance of the bacilli entering the wound and giving him lockjaw. It is popularly thought that wounds in the region of the thumb are most often followed by the disease, but this is not a fact. Wounds about the thumb are of common occurrence, but they are not, in proportion, more often the starting point of tetanus.

Acute traumatic tetanus is very deadly, and up to the present time nothing has been discovered to check or guide its almost certainly fatal course. It often picks out the young and vigorous as its victims—the athlete, for instance, who meets with some mishap in the field or on the road, the gardener who pricks his hand, the swimmer who cuts his foot, the wounded soldier on the field of battle. The violent muscular contractions are distressingly painful; and the brain remaining perfectly clear throughout, the unhappy individual feels that the vice-like gripping of his muscles is steadily exhausting him and bringing him down. The spasms of tetanus differ from those caused by the administration of strychnine in that the muscles are all the time hard from rigid contraction, the acute spasmodic attacks being superadded, as it were. In poisoning by strychnine the muscles are quite relaxed between the spasmodic attacks.

Tetanus may follow a mere prick or scratch or a severe surgical operation. It not seldom complicates burns, gunshot wounds and injuries caused by the untimely explosion of fireworks. It may be met with in the woman in child-bed or in the newly-born infant. But wherever it occurs it is due to the one cause—to the reception into some wounded surface of the specific germs.

In hot countries tetanus is more common and more acute than it is in temperate climes, and a case has been recorded in which a man in the West Indies cut his hand on a broken plate at dinner and was dead of tetanus before the day was out. It is easy to see that the germs are more likely to undergo virulent cultivation in warm earth than in cold. It was formerly the custom to speak of idiopathic tetanus—that is to say, of the disease occurring without any wound having been received. But modern teaching is to the effect that there must have been some wound, however slight, by which the germs found entrance. Rheumatic tetanus is as unreal a disease as that just mentioned. The germs themselves do not wander from the wound to multiply in the blood as in infecting diseases, but remaining at the wound elaborate a terribly poisonous substance (a toxin) which makes its way along the nerve-trunks to the spinal cord. Even prompt amputation, however, is likely to prove ineffectual as regards cure, for the germs in the wound have in this growth set free so virulent a poison (toxin) that the nerves of the voluntary muscles all over the body are hopelessly under its influence.

The first symptom of the disease is discomfort in the back of the neck; the man waking up in the morning, for instance, complains of "stiff neck" and of obscure pains, and wonders if he has been lying in a draught. Then the muscles of the jaw and of the face become affected, there being a difficulty in opening the mouth, and the corners of the mouth are drawn downwards and backwards, and fixed in that position (*risus sardonicus*). The jaw is so firmly set that it is impossible to pass anything between the teeth. All food, therefore, has to be fluid, and being poured into the pouch of the cheek, finds its way into the mouth by the serviceable gap which exists behind the wisdom-teeth. Soon, however, a difficulty in swallowing comes on because of the muscles of the throat being involved. The muscles of the abdomen becoming contracted are rigidly fixed, and on laying the hand upon the front of the abdomen they feel as "hard as a board." The muscles of the limbs are also attacked with fearful cramps, and, last of all, the muscles of the chest are involved. Though all these muscles are in a continuous state of contraction, spasmodic contractions, as already remarked, come on in addition, and occasionally with such distressing energy that the patient is doubled up forwards, backwards, or sideways, and, may be, some of the muscles tear across. The patient is bathed in perspiration, and sinks worn out and exhausted, or, perchance, slowly suffocated by the locking of the muscles of respiration.

As regards the prospect of recovery in tetanus it may be said that when the symptoms break out acutely within a week of the reception of an injury the prospect of recovery is extremely remote. If they occur within ten days the prospects are bad. But if there is an interval of three weeks or a fortnight before their occurrence the case may be regarded more hopefully.

In the treatment of tetanus the first thing to do is to try to make the wound by which infection has taken place surgically clean. For though a wound free from the germs of suppuration may be the incubating place of the bacilli of tetanus, still in most cases there is also an invasion of septic germs, and the double infection makes the action of the tetanic poison the more virulent. If the local conditions are such that it is impossible to cleanse the wound, the free use of the knife or of the cautery or of pure carbolic acid may be resorted to, or an amputation may be performed. But even the early amputation of the infected part may not avail for the reason that the germs in the wound have already set free a lethal dose of their toxin.

The wound having been cleansed the further treatment of the disease demands absolute quiet in a darkened room. There must be no slamming of the door, shaking of the bed, or the sudden bringing in of a light, for any act such as this might cause the outbreak of a violent spasm. Morphia may be given by the hypodermic syringe, and if the spasms are causing great distress chloroform may be administered; indeed, in certain severe cases it may be necessary to keep the patient almost continuously under its influence. If there is difficulty in swallowing fluid, rectal feeding must be resorted to. Though at present one is unable to speak enthusiastically or with confidence about the antitoxin treatment of lockjaw, still it is a method which should certainly be given trial—and that early. The tetano-antitoxin is prepared from the blood of animals which have been rendered immune to repeated injections of the poison elaborated by the cultivation of the tetanus bacilli. The bacilli themselves are not injected, the injections being rendered sterile. By passing the sterile injections into one of the lower animals the blood of that animal prepares an antidote to them known as an antitoxin.

The antitoxin may be injected into the nerve trunks or into the sheath of the spinal cord or of the brain. But inasmuch as the nerves and the nerve-cells are under the influence of the toxin before the antitoxin is administered—as evidenced by the occurrence of the symptoms—the injection-treatment has but a poor chance of producing a good effect. (E. O.*)

TETRADYMITE, a mineral consisting of bismuth telluride and sulphide, Bi_2Te_2S, also known as "telluric bismuth." Sometimes sulphur is absent and the formula is then Bi_2Te_3; traces of selenium are usually present. Crystals are rhombohedral, but are rarely distinctly developed; they are twinned together in groups of four; hence the name of the mineral, from the Greek, τετραδυμος, fourfold. There is a perfect cleavage parallel to the basal plane; and the mineral usually occurs in foliated masses of irregular outline. The colour is steel-grey, and the lustre metallic and brilliant. The mineral is very soft ($H=1\frac{1}{2}$) and marks paper; the specific gravity is 7·2 to 7·6. It was first found, in 1815, at Telemarken in Norway; crystals are from Schubkau near Schemnitz in Hungary. It often occurs in quartz associated with native gold. Other species very similar to tetradymite, but with different formulae, are: *joseite*, from San José near Marianna in Brazil; *grünlingite* (Bi_4S_3Te), from Caldbeck Fells in Cumberland; and *wehrlite*, from Hungary. (L. J. S.)

TETRAGRAMMATON (τέτταρα, four; γράμμα, letter), a Greek compound, found in Philo and Josephus, which designates the divine name composed of the four Hebrew letters J H V H (יהוה). The derivation and pronunciation of the Tetragrammaton is still doubtful. The form "Jehovah" (*q.v.*) used in some of the English Versions is an error which arose in the 16th century. It is now generally assumed that the word is the causative form (*hiph'il*) and should be pronounced Yahveh or Yahweh (accent on second syllable). The Jews quite early ceased to pronounce the Tetragrammaton, substituting (as the Books of Chronicles and the LXX translation already indicate) the word Lord (*'Adonai*). The priests continued to use the name in the Benediction of the People (Numbers vi. 22–27), and on the Day of Atonement the High Priest pronounced it (Leviticus xvi. 30) amidst the prostrations of the assembled multitude. It is recorded in the Talmud that Rabbis communicated the true pronunciation to their disciples once in seven years (*Qiddushin*, 71a). The Jews called the Tetragrammaton by a Hebrew denomination, *Shem Hammephorash* (שם המפורש), *i.e.* the distinctive excellent name. It was considered an act of blasphemy for a layman to pronounce the Tetragrammaton. This avoidance of the original name was due on the one hand to reverence and on the other to fear lest the name be desecrated by heathens. Partly in consequence of this mystery and partly in accord with widespread superstitions, the Tetragrammaton figures in magical formulae from the time of the Gnostics, and on amulets. Many a medieval miracle-worker was supposed to derive his competence from his knowledge of the secret of the Name.

TETRAHEDRITE, a mineral consisting typically of copper sulph-antimonite, Cu_3SbS_3, but often of complex composition. The copper is usually isomorphously replaced by variable amounts of silver, iron, zinc, mercury, lead or cobalt, and the antimony by arsenic or bismuth. In general, the formula is $R'_6X_2S_6+xR''_6X_2S_9$, where $R'=Cu$, Ag; $X=Sb$, As, Bi; $R''=Fe$, Zn, and x is a small fraction, often $\frac{1}{10}$ or $\frac{1}{5}$. Numerous special names have been applied to varieties differing in chemical composition; the arsenic compound, Cu_3AsS_3, is known as tennantite (after Smithson Tennant). The old German name *Fahlerz* includes both tetrahedrite and tennantite, and so does the term "grey copper ore" of miners. Tetrahedrite is an important ore of copper, the formula Cu_3SbS_3, corresponding with 57·5 per cent. of this metal; it is also largely worked as an ore of silver, of which element it sometimes contains as much as 30 per cent. Well-developed crystals are of frequent occurrence; they belong to the tetrahedral class of the cubic system, and their tetrahedral form is a very characteristic feature of the mineral, which for this reason was named tetrahedrite. Fig. 1

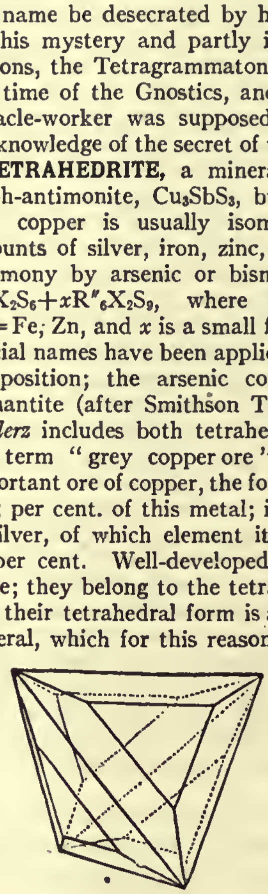

FIG. 1.

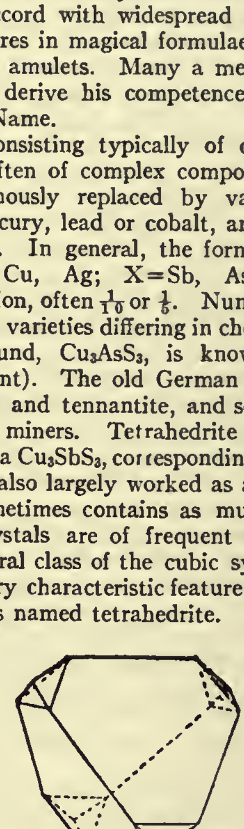

FIG. 2.

Crystals of Tetrahedrite.

shows a combination of a tetrahedron and a triakis-tetrahedron {211}, and fig. 2 a tetrahedron with the rhombic dodecahedron. Interpenetrating twinned crystals sometimes occur. The colour is steel-grey to iron-black, and the lustre metallic and brilliant. The streak is usually black; sometimes, however, it is dark cherry-red, and very thin splinters of the mineral then transmit a small amount of blood-red light. The hardness is $4\frac{1}{2}$, and the specific gravity varies with the composition from 4·4 to 5·1. There is no cleavage, and the fracture is conchoidal. The material is often very impure owing to intimate intermixture with chalcopyrite.

Tetrahedrite occurs in metalliferous veins associated with chalcopyrite, pyrites, blende, galena, &c. Fine groups of crystals, coated on their surface with brassy or brilliantly tarnished chalcopyrite, were formerly found at Herodsfoot mine, near Liskeard in Cornwall. Good crystals are also met with at Kapnik-Banya in Hungary, in the Harz, Peru, and other places. Tennantite occurs as small crystals of cubic or dodecahedral habit in many

Cornish copper mines, especially in the neighbourhood of Redruth: it is also found as small, brilliant crystals very rich in faces in the white crystalline dolomite of the Binnenthal in the Valais, Switzerland, and under the name binnite was long considered as a distinct species. (L. J. S.)

TETRAHEDRON (Gr. τέτρα-, four, ἕδρα, face or base), in geometry, a solid bounded by four triangular faces. It consequently has four vertices and six edges. If the faces be all equal equilateral triangles the solid is termed the "regular" tetrahedron. This is one of the Platonic solids, and is treated in the article POLYHEDRON, as is also the derived Archimedean solid named the "truncated tetrahedron"; in addition, the regular tetrahedron has important crystallographic relations, being the hemihedral form of the regular octahedron and consequently a form of the cubic system. The bisphenoids (the hemihedral forms of the tetragonal and rhombic bipyramids), and the trigonal pyramid of the hexagonal system, are examples of non-regular tetrahedra (see CRYSTALLOGRAPHY). "Tetrahedral co-ordinates" are a system of quadriplanar co-ordinates, the fundamental planes being the faces of a tetrahedron, and the co-ordinates the perpendicular distances of the point from the faces, a positive sign being given if the point be between the face and the opposite vertex, and a negative sign if not. If (u, v, w, t) be the co-ordinates of any point, then the relation $u+v+w+t=\mathrm{R}$, where R is a constant, invariably holds. This system is of much service in following out mathematical, physical and chemical problems in which it is necessary to represent four variables.

Related to the tetrahedron are two spheres which have received much attention. The "twelve-point sphere," discovered by P. M. E. Prouhet (1817–1867) in 1863, is somewhat analogous to the nine-point circle of a triangle. If the perpendiculars from the vertices to the opposite faces of a tetrahedron be concurrent, then a sphere passes through the four feet of the perpendiculars, and consequently through the centre of gravity of each of the four faces, and through the mid-points of the segments of the perpendiculars between the vertices and their common point of intersection. This theorem has been generalized for any tetrahedron; a sphere can be drawn through the four feet of the perpendiculars, and consequently through the mid-points of the lines from the vertices to the centre of the hyperboloid having these perpendiculars as generators, and through the orthogonal projections of these points on the opposite faces.

TETRARCH (τετράρχης), the ruler of a tetrarchy, that is, in the original sense of the word, of one quarter of a region. Such were the tetrarchies of Thessaly as reconstructed by Philip of Macedon and of Galatia before its conquest by the Romans (169 B.C.). In later times the title of tetrarch is familiar from the New Testament as borne by certain princes of the petty dynasties which the Romans allowed to exercise a dependent sovereignty within the province of Syria. In this application it has lost its original precise sense, and means only the ruler of part of a divided kingdom, or of a district too unimportant to justify a higher title. After the death of Herod the Great (4 B.C.) his realm was shared among his three sons: the chief part, including Judaea, Samaria and Idumaea, fell to Archelaus (Matt. ii. 22), with the title of ethnarch (Josephus, *Antiq.*, xvii. 11, 4); Philip received the north-east of the realm and was called tetrarch; and Galilee was given to Herod Antipas, who bore the same title (Luke iii. 1). These three sovereignties were reunited under Herod Agrippa from A.D. 41 to 44. In the same passage of Luke mention is made of Lysanias, tetrarch of Abilene near Damascus, in the valley of the Barada.

TETRASTOÖN (Gr. τέτρα-, four, and στοά, a portico), the term in architecture given to a rectangular court round which on all four sides is carried a covered portico or colonnade; the same as peristyle (*q.v.*).

TETRASTYLE (Gr. τέτρα-, four, and στῦλος, a column), the term in architecture given to a portico of four columns which forms the main front of a temple (*q.v.*).

TETRAZINES, in organic chemistry, a group of compounds containing the ring system

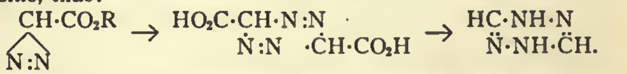
$$\begin{matrix}\mathrm{C{\cdot}N{\cdot}N}\\ \dot{\mathrm{C}}\mathrm{{\cdot}N{\cdot}}\dot{\mathrm{N}},\end{matrix}\ \text{or}\ \begin{matrix}\mathrm{C{\cdot}N{\cdot}N}\\ \dot{\mathrm{N}}\mathrm{{\cdot}N{\cdot}}\dot{\mathrm{C}},\end{matrix}\ \text{or}\ \begin{matrix}\mathrm{C{\cdot}N{\cdot}C}\\ \dot{\mathrm{N}}\mathrm{{\cdot}N{\cdot}}\dot{\mathrm{N}};\end{matrix}$$

only derivatives of the first two types are known. The members of the first series may be prepared by oxidizing osazones (*i.e.* dihydrazones of α-diketones), dihydrotetrazines resulting. Dihydro-derivatives of the second type are formed from hydrazine and imino-ethers (A. Pinner, *Ber.*, 1893, 26, p. 2126; 1894, 27, p. 984); these easily oxidize to the corresponding tetrazines, which are stable towards acids; their dihydro-derivatives, however, are decomposed, the group—NH·NH—being eliminated as hydrazine and replaced by oxygen, with consequent formation of the five membered oxybiazole ring. Concentrated acids convert the dihydro-tetrazines into isodihydrotetrazines, thus:—

$$\begin{matrix}\mathrm{R{\cdot}C{\cdot}NH{\cdot}NH}\\ \dot{\mathrm{N}}\mathrm{{\cdot}N\ {:}}\dot{\mathrm{C}}\mathrm{{\cdot}R}\end{matrix}\rightarrow\begin{matrix}\mathrm{R{\cdot}C{\cdot}NH{\cdot}N}\\ \dot{\mathrm{N}}\mathrm{{\cdot}NH{\cdot}}\dot{\mathrm{C}}\mathrm{{\cdot}R},\end{matrix}$$

the N-alkyl derivatives of which type may be prepared by the action of alcoholic potash and chloroform on aromatic hydrazines.

Much discussion has circulated about the decomposition of diazo-acetic ester, from which A. Hantzsch and O. Silberrad (*Ber.*, 1900, 33, p. 58) obtained what they considered to be a dihydrotetrazine, thus:—

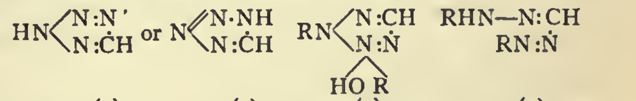


C. Bülow (*Ber.*, 1906, 39, pp. 2618, 4106), however, showed this substance to be an N-aminotriazole, which necessitates the first decomposition product being an acid (I.), the conversion into the

$$(\mathrm{I.})\ \begin{matrix}\mathrm{HO_2C{\cdot}C{\cdot}NH{\cdot}NH}\\ \dot{\mathrm{N}}\mathrm{{\cdot}N{:}\ }\dot{\mathrm{C}}\mathrm{{\cdot}CO_2H}\end{matrix}\rightarrow(\mathrm{II.})\ \begin{matrix}\mathrm{HO_2C{\cdot}C{-}N{\cdot}NH_2}\\ \dot{\mathrm{N}}\mathrm{{\cdot}N{:}}\dot{\mathrm{C}}\mathrm{{\cdot}CO_2H}\end{matrix}$$

triazole derivative (II.) being due to the ring opening on the addition of the elements of water and then closing again to the five-membered ring with elimination of water again. The decompositions of diazoacetic ester were then again examined by T. Curtius and his students (*Ber.*, 1907, 40, pp. 262, 350, 450, &c.), who showed that both triazole and tetrazine derivatives could be obtained from the bisdiazo-acetic acid which is formed by the action of alkali on diazo-acetic ester.

TETRAZOLES, in organic chemistry, a group of heterocyclic compounds, capable of existing in two isomeric series (formulae 1 and 2), although the methods of preparation do not always permit discrimination between the possible isomers. They are prepared by the action of nitrous acid on cyanamidrazone (dicyanophenylhydrazine) and hydrolysis of the resulting nitrile, from which J. A. Bladin by elimination of the phenyl group (by nitration, reduction, &c.) and of carbon dioxide obtained free tetrazole, $\mathrm{CH_4N_2}$; from amidines by the action of nitrous acid, followed by the reduction of the intermediately formed dioxytetrazotic acids with sodium amalgam; from amidoguanidine by diazotization, the diazonium nitrate on treatment with acetates or carbonates yielding aminotetrazole (J. Thiele, *Ann.*, 1892, 270, p. 1); from the action of nitrous acid on phenylthiosemicarbazide; and by the action of arylazoimides on aldehyde hydrazones (O. Dimroth, *Ber.*, 1907, 40, p. 2402). The tetrazoles behave as strong monobasic acids, and are exceedingly stable. A series of tetrazolium bases (formula 3) have been obtained by H. V. Pechmann (*Ber.*, 1894, 27, p. 2920) starting from formazyl compounds (formula 4), which are oxidized by means of amyl nitrite and hydrochloric acid. They are strong bases, which in aqueous solution absorb carbon dioxide readily. The free bases have not been isolated, but their salts are well-crystallized solids.



(1), (2). (3), (4).

TETSCHEN, a town of Bohemia, Austria, 83 m. N.N.E. of Prague by rail. Pop (1900) 9692, exclusively German. It is situated at the confluence of the Polzen with the Elbe, on the right bank of the latter river opposite Bodenbach (*q.v.*), with which it is connected by a chain bridge (1855) and two railway bridges. The handsome château of the counts of Thun (built in 1667–73 and restored in 1788), which occupies a rocky height above the town, was at one time fortified, and was a place of some importance during the Seven Years' War. It contains a magnificent library, with many valuable MSS. and fine collections of coins and armour. In addition to being the principal emporium for the Austrian traffic on the Elbe, Tetschen has a considerable industry, its products comprising chemicals, oil, soap, cotton stuffs, plaster of Paris, glazed and coloured paper, cellulose, beer, flour and preserved fish.

The town of Tetschen originally lay on the south side of the castle rock, but after its destruction by a flood, it was moved in 1059 to its present site. In 1305 it came into the hands of the knights of Wartenberg, who held it for two hundred years. In 1534 the Saxon lords of Bünau obtained it and introduced the Protestant religion, which was exterminated when, after the battle of the White Hill (1620) the Bünau family was driven out. The lordship was bought from them in 1628 by the Freiherr von Thun, by whose descendants, the Counts Thun, it is still held.

TETUAN (Tettāwan), the only open port of Morocco on the Mediterranean, a few miles S. of the Strait of Gibraltar, and about 40 m. E.S.E. of Tangier. Population about 25,000, of whom a fifth are Jews. It is picturesquely situated on the northern slope of a fertile valley down which flows the W. Martil, with the harbour of Tetuan, Martil, at its mouth. Behind rise rugged masses of rock, the southern wall of the Anjera country, practically closed to Europeans, and across the valley are the hills which form the northern limit of the still more impenetrable Rif. In point of cleanliness Tetuan compares favourably with most Moorish towns. The streets are fairly wide and straight, and several of the houses belonging to aristocratic Moors, descendants of those expelled from Spain, have fine courts surrounded by arcades, some with marble fountains and planted with orange trees. Within the houses the ceilings are often exquisitely carved and painted in Mauresque designs, such as are found in the Alhambra, and the tile-work for which Tetuan is known may be seen on floors, pillars and dados. The principal industries are tilework, inlaying with silver wire, and the manufacture of thick-soled yellow slippers, much-esteemed flintlocks, and artistic "towels" used as cape and skirt by Moorish country girls. The Jews live in a *mellah*, separated from the rest of the town by gates which are closed at night. The harbour of Tetuan is obstructed by a bar, over which only small vessels can pass, and the roadstead, sheltered to the N., N.W. and S., is exposed to the E., and is at times unsafe in consequence of the strong Levanter.

The present town of Tetuan dates from 1492, when the Andalusian Moors first reared the walls and then filled the enclosure with houses. It had a reputation for piracy at various times in its history. It was taken on the 4th of February 1860 by the Spaniards under O'Donnell, and almost transformed by them into a European city before its evacuation on the 2nd of May 1862, but so hateful were the changes to the Moors that they completely destroyed all vestiges of alteration and reduced the city to its former state. (K. A. M.*)

TETZEL, JOHANN (*c.* 1460–1519), preacher and salesman of papal indulgences, the son of Hans Tetzel, a goldsmith of Leipzig, was born there about 1460. He matriculated at the university in 1482, graduated B.A. in 1487, and in 1489 entered the Dominican convent at Leipzig. He early discovered his vocation as a preacher of indulgences; he combined the elocutionary gifts of a revivalist orator with the shrewdness of an auctioneer. He painted in lurid colours the terrors of purgatory, while he dwelt on the cheapness of the indulgence which would purchase remission and his prices were lowered as each sale approached its end. He began in 1502 in the service of the Cardinal-legate Raymond Peraudi; and in the next few years he visited Freiberg (where he extracted 2000 gulden in two days), Dresden, Pirna, Leipzig, Zwickau and Görlitz. Later on he was at Nuremberg, Ulm and Innsbruck, where he is said to have been condemned to imprisonment for adultery, but released at the intercession of the elector of Saxony. This charge is denied by his apologists; and though his methods were attacked by good Catholics like Johann Hass, he was elected prior of the Dominicans in Glogau in 1505.

Fresh scope was given to his activity in 1517 by archbishop Albrecht of Mainz. Albrecht had been elected at the age of twenty-four to a see already impoverished by frequent successions and payments of annates to Rome. He had agreed with Pope Leo X. to pay his first-fruits in cash, on condition that he were allowed to recoup himself by the sale of indulgences. Half the proceeds in his province were to go to him, half to Leo X. for building the basilica of St Peter's at Rome. Tetzel was selected as the most efficient salesman; he was appointed general sub-commissioner for indulgences, and was accompanied by a clerk of the Fuggers from whom Albrecht had borrowed the money to pay his first-fruits. Tetzel's efforts irretrievably damaged the complicated and abstruse Catholic doctrine on the subject of indulgences; as soon as the coin clinks in the chest, he cried, the soul is freed from purgatory. In June he was at Magdeburg, Halle and Naumburg; the elector of Saxony excluded him from his dominions, but Albrecht's brother, the elector Joachim of Brandenburg, encouraged him at Berlin in the hope of sharing the spoils, and by the connivance of Duke George of Saxony he was permitted to pursue his operations within a few miles of the electoral territory at Wittenberg. Luther was thus roused to publish his momentous ninety-five theses on the subject of indulgences on October 31, 1517 (see Luther).

Even Albrecht was shamed by Luther's attack, but he could not afford to relinquish his profits already pledged for the repayment of his debts; and Tetzel was encouraged to defend himself and indulgences. Through the influence of Conrad Wimpina, rector of Frankfurt, Tetzel was created D.D. of that university, and with Wimpina's assistance he drew up, in January 1518, a hundred and six theses in answer to Luther's. But the storm overwhelmed him: sober Catholics felt that his vulgar extravagances had prejudiced Catholic doctrine, and Miltitz, who was sent from Rome to deal with the situation, administered to him a severe castigation. He hid himself in the Dominican convent at Leipzig in fear of popular violence, and died there on the 4th of July 1519, just as Luther was beginning his famous disputation with Eck.

Many lives of Tetzel have been published on the Protestant and on the Catholic side, the most recent being Körner's (1880), K. W. Hermann's (2nd ed. 1883), and N. Paulus' (1899). See also *Allgemeine deutsche Biographie*; Gess's *Akten und Briefe zur Kirchenpolitik Herzog Georgs von Sachsen*, vol. i. (1905), Introd. pp. 76–8, &c.; H. Barge's *Andreas Bodenstein von Carlstadt* (2 vols. 1905); J. Janssen's *Hist. of the German People*, and *An meine Kritiker*; M. Creighton's *Hist. of the Papacy*, vol. vi.; and H. C. Lea's *Hist. of Auricular Confession and Indulgences* (3 vols., 1896). All the histories of the Reformation in Germany and all the lives of Luther deal at greater or shorter length with Tetzel; in the index to vol. ii. of the *Cambridge Mod. History* he is confused with a later Tetzel of Nuremberg. (A. F. P.)

TEUFFEL, WILHELM SIEGMUND (1820–1878), German classical scholar, was born at Ludwigsburg in the kingdom of Württemberg on the 27th of September 1820. In 1849 he was appointed extraordinary, in 1857 ordinary professor in the university of Tübingen, which post he held till his death on the 8th of March 1878. His most important work was his *Geschichte der römischen Litteratur* (1870; 5th ed. by L. Schwabe, 1890; Eng. tr. by G. C. Warr, 1900), which, although written in an unattractive style, is indispensable to the student, the bibliographical information being especially valuable. After the death of A. Pauly, the editor of the well-known *Real-Encyclopädie der classischen Altertumswissenschaft*, Teuffel, at first assisted by E. C. Walz, undertook the completion of the work, to which he also contributed numerous articles.

He was also the author of "Prolegomena zur Chronologie der horazischen Gedichte" (in *Zeitschrift für die Altertumswissenschaft*, 1842); *Charakteristik des Horaz* (Leipzig, 1842); *Horaz, eine litterar-historische Übersicht* (Tübingen, 1843), and of editions of the *Clouds* of Aristophanes (1856) and the *Persae* of Aeschylus (1866). His *Studien und Charakteristiken* (1871; 2nd ed., 1889) contain valuable contributions to the history of Greek and Roman literature. See S. Teuffel, *Wilhelm Teuffel* (1889); C. Bursian in *Biographisches Jahrbuch* (1878); F. Koldewey in *Allgemeine deutsche Biographie*, xxxvii.

TEUTOBURGER WALD, a mountain range of Germany, stretching N.W. to S.E., along the borders of the Prussian provinces of Hanover and Westphalia and through the principality of Lippe, for a distance of 70 m., with a width of 2 to 6 m. It consists of a well-marked main chain, accompanied in its central part by subsidiary ridges. It slopes up gradually towards the E., where it culminates in the Völmerstod (1536 ft.). The greater part of the range is densely wooded. The main chain is pierced by several deep gaps or "doors," through some of which important railways have been carried; *e.g.*, the line connecting Paderborn and Hanover, and that connecting Herford and Hamm. The chief geological formations belong to the Cretaceous system, backed towards the north and east by Jurassic and Triassic formations. The Teutoburger Wald was the scene of a famous battle in which Arminius at the head of the Cherusci destroyed three Roman legions under Quintilius Varus (A.D. 9). Mommsen has located the battle near the source of the Hunte, north of Osnabrück, and outside the range of hills; but most scholars prefer some site in the central part of the mountain-chain. In accordance with these latter views the Grotenburg (1263 ft.), 2½ m. S.W. from Detmold, has been crowned with a gigantic monument to Arminius Hermann, erected in 1838–41 and 1871–75, at a cost of £13,500. The work, which was designed by E. von Bandel, consists of a gigantic statue of the chieftain, 56½ ft. high, standing on an arched pediment 98 ft. high.

See H. Thorbecke, *Führer durch den Teutoburger Wald* (15th ed., Detmold, 1905); Wilisch, *Der Kampf um das Schlachtfeld im Teutoburger Walde* (*Neue Jahrbücher für das klassische Altertum*, May 1909).

TEUTONI, or TEUTONES, a tribe of northern Europe, who became known to the Romans in the year 103 B.C., when, according to the *Epitome* of Livy, together with the Ambrones they reinforced the Cimbri (*q.v.*) after their repulse from Spain by the Celtiberi. In 102 the Teutoni and Ambrones were totally defeated by Marius at Aquae Sextiae (see MARIUS, GAIUS). The racial affinities of the Teutoni have formed a matter of dispute amongst historians. Their name is Celtic in form, and many writers suppose that the Teutoni were really a Celtic tribe, a branch of the Helvetii. But a people of this name seems to have been mentioned by the early traveller Pytheas as inhabiting the coasts of the northern ocean in his time. Strabo and Velleius, moreover, classify them as Germani, and this is perhaps the more probable view, although apparently the distinction between Celt and Teuton was not clearly realized by some of the earlier historians. If the Teutoni really came from the same quarter as the Cimbri, it is possible that their name may have been preserved in that of the district called until recently Thyland or Thythsyssel in the extreme north-west of Jutland.

For authorities see CIMBRI; also Pliny, xxxvii. 35.

(F. G. M. B.)

TEUTONIC (GERMANIC) LANGUAGES,[1] a comprehensive term for a number of languages most of which are still spoken at the present time, namely English, Frisian, Dutch, Flemish, German (both High and Low) and the various Scandinavian languages (Swedish, Danish, Icelandic and the Norwegian dialects). The course of time has tended very largely to obscure the affinities between these languages, and in several cases they have been mutually unintelligible for many centuries. In their earliest known forms, however, they betray the most unmistakable traces of a common origin. To the languages enumerated above we have to add the now extinct Gothic, which in the 5th and 6th centuries was spoken over a large part of Europe.

Detailed accounts of the various Teutonic languages will be found in articles under the respective headings. Here it is possible only to give a brief summary of the chief characteristics of these languages as a group, and of the chief divergences noticeable in early times between the various members of the group. It should be noted at the outset that the written records of the various languages date from very different periods. Gothic is known to us almost entirely from Ulfilas' translation of the Bible, which dates from the 4th century. English written literature starts with the beginning of the 7th century, though earlier matter may be preserved in certain poems. The earliest known German and Dutch documents date from the 8th and 9th centuries respectively, while Frisian is practically unknown before the 13th century. Scandinavian written literature seems to have begun in the 12th century, but many poems are probably from two to three centuries older. In the North there are also a large number of inscriptions which are of great value for linguistic purposes. Most of them cannot be dated with certainty, but the forms of language which they present show all stages of development, from the type found in literary times back to one which is somewhat more archaic even than Gothic. It is probable that the earliest of them date from between the 3rd and 5th centuries. The inscriptions found in England and Germany are much fewer and less archaic. In the latter case, however, a good deal of linguistic evidence is available from the proper names and other Teutonic words which occur in early Latin and Greek writings. Much assistance may also be obtained from the loan-words borrowed by Teutonic languages from Latin and by other languages, especially Finnish and Slavonic, from Teutonic.

The Teutonic languages form a distinct and well-defined group of the Indo-European family. Their nearest affinities are on the one side with the Celtic and Italic (Latin, &c.) languages, and on the other with the Slavonic and Baltic languages. In regard to the fundamental distinction, however, by which the Indo-European languages as a whole fall into two main divisions, namely according to the treatment of certain guttural and palatal consonants, the Teutonic group belongs definitely, together with Celtic, Italic and Greek, to the western of these divisions.

The chief characteristic of the Teutonic languages as a whole lies in their treatment of the Indo-European explosive sounds. This characteristic, generally known as Grimm's Law, is due to sound-changes peculiar to Teutonic, though somewhat similar changes may be traced both in Armenian and Celtic. The most noteworthy phenomena are as follows:—

(1) The Indo-European voiced aspirates, *bh*, *dh*, *gh* (Lat. *f*, *f*, *h*; Gk. φ, θ, χ) became voiced spirants, ƀ, đ, ȝ. After nasals these spirants became explosives (*b*, *d*, *g*); and in the first two cases the same change took place initially, though hardly during the early centuries of our era, *e.g.* A.S. *beran*, O.N. *bera* : Lat. *fero*, Gk. φέρω; A.S. *stigan* : Gk. στείχω; O.N. *miöðr* (A.S. *medu*) : Gk. μέθυ.

(2) The I.-Eur. voiceless explosives, *p*, *t*, *k*, were preserved only after *s* (*t* also in the I.-Eur. groups *pt* and *kt*); *e.g.* A.S. *stede*, Goth. *staþs*: Gk. στάσις; Goth. *nahts*: Lat. *noctem*. In all other cases they became voiceless spirants, *f*, *þ*, χ, (*h*). These new sounds remained (i.) initially, *e.g.* A.S. *hwaet*, O.N. *hvat*: Lat. *quod*; A.S. *faeder*, O.N. *faðir* : Lat. *pater*; (ii.) in combination with other voiceless sounds, *e.g.* Goth. *saihs*, O.H.G. *sehs*: Lat. *sex*; Goth. *nahts*: Lat. *noctem*; (iii.) immediately after the (original) accent, *e.g.* Goth. *broþar*, A.S. *broðor* : Lat. *frater*, Gk. φράτηρ; Goth. *taihun*, O.H.G. *zehan*: Lat. *decem*, Gk. δέκα. In all other cases they became voiced spirants ("Verner's Law"), identical with those arising from I.-Eur. *bh*, *dh*, *gh* (see above); *e.g.* A.S. *faeder*: Lat. *pater*, Gk. πατήρ; A.S. *sweger*, O.H.G. *swigar* (mother-in-law): Gk. ἑκυρά.

(3) The I.-Eur. voiced (unaspirated) explosives, *b*, *d*, *g*, became voiceless, *p*, *t*, *k*; *e.g.* A.S. *etan* : Lat. *edere*; A.S. *aecer*, Goth. *akrs*: Lat. *ager*, Gk. ἀγρός.

Among other consonantal changes we may note especially the following:—

(4) ȝ*w* arising from I.-Eur. *ghw* or *kw* (see above) was reduced (except after nasals) before *u* (perhaps also before I.-Eur. *o*) to ȝ, and in all other cases to *w*; *e.g.* A.S. *guð* (war), O.H.G. *gund*: Gk. -φατος (cf. φόνος); A.S. *sniweð* (snows): Lat. *niuit*, Gk. νείφει.

(5) The I.-Eur. cons. group arising from combination of dental sound +*t* became *ss*, as in Celtic and Latin, *e.g.* A.S. *sess* (seat): *sittan*, Lat. *sedere* (cf. Sanscr. pp. *sattas*, Lat. *obsessus*).

[1] The following abbreviations are used: A.S. = Anglo-Saxon; O.H.G. = Old High German; O.N. = Old Norse; I.-Eur. = Indo-European. The symbol ":" denotes relationship between two forms or sets of forms.

(6) The treatment of I.-Eur. *s* was precisely parallel to that of the voiceless spirants *f*, *þ*, χ arising from I.-Eur. *p*, *t*, *k* (see above). It was preserved (i) initially, (ii) in combination with voiceless sounds, (iii) immediately after the (original) accent. In all other cases it became voiced (*z*). This voiced spirant subsequently became *r* in all Teutonic languages except Gothic, where however the distinction between voiced and voiceless spirants is not well preserved; *e.g.* A.S. *ceosan*, pp. *coren* (*géuso- guséno*): Gk. γεύομαι (cf. Lat. *gustus*); A.S. *snoru*, O.H.G. *snura* (daughter-in-law): Sanscr. *snušá*, Gk. νυός.

Most of the other consonantal changes are in the nature of assimilation.

(7) *ƀn*, *dn*, *ʒn* before the accent became *pp*, *tt*, *kk* (probably through the intermediate stage *bb*, *dd*, *gg*); *e.g.* A.S. *liccian*, O.H.G. *leckon* (from *liʒná-*): Gk. λιχνεύω (cf. Goth. *bi-laigon*).

(8) *ln* became *ll*; *e.g.* A.S. *full*, Goth. *fulls*: Lith. *pilnas*.

(9) *nw* became *nn*; *e.g.* A.S. *þynne*, O.N. *þunnr*: Lat. *tenuis*.

(10) *dl* became *ll*; *e.g.* A.S. *st(e)all*, O.N. *stallr*: Lat. *stabulum* (from *stadhlom*).

(11) In some combinations consonants are lost or new consonants developed; *e.g.* Goth. *sunja* (truth): Lat. *praesentia* (*-sntjā*); O.H.G. *hunno* (centurion) from *hundn-*, cf. Goth. *hund*: Lat. *centum*; A.S. *stream*, O.N. *straumr* from *sroum-*, cf. Gk. ῥεῦμα, Old Irish *sruaim*.

The following changes are found in all Teutonic languages, but took place apparently later than those enumerated above:—

(i) *n* was lost before χ (*h*), with compensatory lengthening of the vowel; *e.g.* A.S. *þōhte*, Goth. *þāhta* beside A.S. *þencean*, Goth. *þagkjan*.

(ii) Final explosives and nasals were lost; *e.g.* A.S. *wile*, Goth. *wili*: Lat. *uelit*; A.S. *ēa*, Goth. *ahwa*: Lat. *aquam*; Goth. *kustu*: Lat. *gustum*.

In its vowel-system the earliest known form of Teutonic did not differ greatly from the other I.-Eur. languages. Its chief peculiarities seem to have been as follows:—

(1) It had one vowel (*a*) corresponding to the two vowels *a*, *o* found in the other I.-Eur. languages; *e.g.* Goth. *akrs*, O.N. *akr*: Lat. *ager*, Gk. ἀγρός; Goth. *ahtau*, O.H.G. *ahto*: Lat. *octo*, Gk. ὀκτώ.

(2) It had also one vowel (*ō*) corresponding to the two vowels *ā*, *ō*, found in the other I.-Eur. languages, *e.g.* A.S. *brōðor*, Goth. *bro þar*: Lat. *frāter*, Gk. φράτηρ; A.S. *rōw* (rest), O.H.G. *ruowa*: Gk. ἐρω(ϝ)ή.

The other I.-Eur. vowels, *ĕ*, *ĭ*, *ŭ*, were preserved in the earliest Teutonic. Soon after the beginning of our era, however, *e* began to change to *i* before a nasal followed by a consonant, *e.g.* Ptol. Φίννοι (A.S. *Finnas*, O.N. *Finnar*) against Tac. *Fenni*. The diphthong *ei* became *ī*; *e.g.* A.S., O.H.G. *stīgan*, O.N. *stīga*: Gk. στείχω (the *ei* of Goth. *steigan* is merely graphic).

The reduced nasal sounds generally written *n̥*. *m̥*, arising from *en*, *ne*, *em*, *me*, &c., in unaccented syllables, became *un*, *um* (rarely *nu*, *mu*), *e.g.* A.S., Goth., &c. *un-* (negative prefix): Lat. *in-*, Gk. ἀ-, ἀν-; A.S., Goth. *hund*: Lat. *centum*, Gk. ἑ-κατόν. Similarly the reduced liquid sounds *r̥*, *l̥* became *ur*, *ul* (rarely *ru*, *lu*); *e.g.* A.S. *furh*: Lat. *porca*; Goth. *þulan*: Lat. *tollo*, Gk. τετλάμεν.

Accent.—In the I.-Eur. languages the position of the accent was originally free—*i.e.*, any syllable in the word could bear the chief accent—variation occurring very frequently, *e.g.* between different cases of the same noun. This freedom of position must have been retained in Teutonic at the time when voiceless spirants (*f*, *þ*, χ, *s*) became voiced (see above). Eventually, however, as in Gaelic (Irish) and at one time also in the Italic languages, the first syllable of every word came to bear the chief accent, the only noteworthy exceptions being certain compound words, more especially verbs compounded with prepositions, which were probably long regarded as more or less independent words. This system of accentuation was intimately connected with the principle of alliteration, the essential characteristic of early Teutonic poetry and the dominant factor in family nomenclature. Alliteration in family names certainly dates from the very beginning of the Christian era, *e.g.* the S-names in one of the princely families of the Cherusci frequently mentioned by Tacitus, and there is also some evidence that Teutonic poetry was alliterative by this time. It is probable, therefore, that the change in the system of accentuation took place not later than the 1st century B.C.

The description of the phonetic characteristics given above applies in general to the Teutonic group of languages as a whole. So far as one can judge from the proper names, &c., which occur in Latin works, the description would probably be true for the time about the beginning of the Christian era. Dialectical differences no doubt already existed, but few of them were so clearly marked that they can now be traced with anything like certainty. The language of the earliest Runic inscriptions does not differ very markedly from this type. The principal changes which we can now detect are as follows:—

(1) *e* became *i*, (i) in the unaccented syllable of dissyllabic and in the least accented syllables of polysyllabic words; *e.g.* *ðohtriz* (inscr.), O.N. *doetr*: Gk. θυγατέρες; (ii) in accented syllables when the following syllable contained *i*, *j*, or *u*; *e.g.* A.S. *mid(d)*, O.N. *miðr*: Lat. *medius*.

(2) *i* became *e* when the following syllable contained *a*, *ē*, *ō*; *e.g.* A.S., O.H.G. *wer*, O.N. *verr* (stem *wera-*): Lat. *uir*.

(3) *u* became *o* when the following syllable contained *a*, *ĕ*, *ō*; *e.g.* (1 sing. pret.) *worahtō* (inscr.), A.S. *wor(o)hte*, O.H.G. *wor(a)hta*: A.S. *wyrcean*, O.H.G. *wurchen*.

(4) *ē* became *ā* always; *e.g.* *-māriz* (inscr.): Goth. *-mers*.

(5) final *a*, *e*, were lost; *e.g.* (1, 3 sing. pret.) *was* (inscr.); cf. Gk. λέλοιπ-α, -ε.

(6) final long vowels were (in general) shortened (*ī*≥*i*, *ō*≥*u*); *e.g.* *liuōu* (inscr.). N. sing. fem. (cf. Gk. ἐχθρά).

(7) final nasals and explosives were lost; *e.g.* *worahtō*, 1 sing. pret. (cf. Gk. ἐτίθην).

These changes appear to have operated in all the northern and western Teutonic languages during the first four centuries of our era, except the change *ē*≥*ā*, which in the extreme west (Frankish) seems not to have taken place until the latter part of the 6th century. Several of them can be traced more or less clearly in Latin writings of the 1st century. The Gothic language, however, seems to have developed on quite different lines. The more important of its changes are as follows:—

(1) *e* became *i* always; *e.g.* *wigs* (road): A.S. *weg*. But *i* later became *e* (written *ai* in Ulfilas' orthography) before *r*, *h*; *e.g.* *hairdeis* (herdsman): O.H.G. *hirti*.

(2) *u* became *o* (written *au*) before *r*, *h*; *e.g.* *baurgs*: A.S. *burg*. (In Ulfilas' orthography the letters transcribed *e*, *o* are used for long vowels only.)

(3) *ai*, *au* became *ē*, *ō*; but the digraphs were still written.

(4) short vowels (except *u*) in final syllables were lost; *e.g.* *dags*, *gasts*: (N. inscr.) *daʒaz*, *-ʒastiz*.

(5) final nasals and explosives were lost; *e.g.* *sunu* (Acc. sing.): Sanscr. *sūnum*.

(6) final long vowels (including those which had become final through the last change) were (in general) shortened (*ī*≥*i*, *ō*≥*a*, *ē*≥*a*); *e.g.* *waurhta* (1 sing. pret.): (N. inscr.) *worahtō*; *liuba* (N. sing. fem.): (N. inscr.) *liubu*.

(7) voiced spirants when final (also before *s*) became voiceless; *e.g.* *baþ* (3 sing. pret. of *bidjan*).

All these changes appear to have taken place before or during the 4th century. The effect of them must have been to render the Gothic language hardly intelligible to a person who spoke a northern or western language, whereas during the same period there is little evidence for differences among the latter languages themselves. At a later date Gothic underwent further changes which do not appear in Ulfilas' version, or only to a slight extent.

(1) *i* became a close *e-* sound; *e.g.* *Venethae* (Jordanes), for *Winid-*.

(2) *u* became a close *o* sound: *e.g.* Ῥόγοι (Procopius): *Rugii*; later *o* became *a* in unaccented syllables; *e.g.* *ūraz* (for *-us*).

(3) *ē* became *ī*; *e.g.* *leikeis* for *lekeis* (not unfrequently in the MSS.).

(4) *ō* became *ū*; *e.g.* *sunjus* for *sunjos*.

The chief sound-changes in the northern and western languages seem to have taken place in the 6th and 7th centuries. Some of these changes were common to all the languages in question, some to English and Scandinavian, some to English and German, while others again occurred in only one of these languages or a portion of it.

I. Among the chief changes common to English, Scandinavian and German we may reckon (1) the loss of final *a* (in Scand. also before final consonants); *e.g.* A.S., O.N., O.H.G. *horn* (N. inscr. *horna*); (2) the loss of unaccented *i*, *u* after long syllables, *e.g.* A.S. *hond*, O.N. *hǫnd*, O.H.G. *hant*: Goth. *handus*; (3) the change *z*≥*r* before vowels or *g*; *e.g.* A.S. *dēor*, O.N. *dýr*, O.H.G. *tior*: Goth. (plur.) *diuza*.

II. Among the most important of the changes common to English and Scandinavian must be classed (1) the affection (*umlaut*) of vowels by the vowels (generally *i*, *u*) of following syllables; *e.g.* A.S. *cyn(n)*, O.N. *kyn*: O.H.G. *kunni*; A.S. *geofu*, O.N. *giof*: O.H.G. *geba*. In early German the only case of this kind was the affection of *a* by a following *i* and even this seems to have taken place much later. To the same category we must reckon (2) the early loss of *h* between sonants, *e.g.* A.S. *sēon*, *sīan*, O.N. *siá*: O.H.G. *sehan*; (3) the loss of *n* before *s*, *e.g.* A.S. *ōs*, O.N. *áss*: O.H.G. *Ans–*.

III. Among the chief changes common to English and German were the following: (1) The loss of final *z*; *e.g.* A.S. *daeg*, O.H.G. *tag*: O.N. *dagr* (N. inscr. *dazaz*). In short monosyllables, however, *z* became *r* in High German, as in Scandinavian; *e.g.* *mir* (Dat.): A.S. *mē*, O.-Sax. *mī*, O.N. *mér*, Goth. *mis*. (2) The change *z*>*r* before *d* (whereas assimilation took place in Scand.), *e.g.* A.S. *hord*, O.H.G. *hort*: O.N. *hodd*, Goth. *huzd*. (3) The change *đ*>*d* in all positions (in Scand. only initially and after *l*), *e.g.* A.S. *faeder*, O.-Sax. *fader* (O.H.G. *fater*): O.N. *faðir*. (4) The lengthening of all consonants (except *r*) before *j* (in Scand. only gutturals), *e.g.* A.S. *biddan*, O.H.G. *bitten*: O.N. *biðia*.

The sound-changes peculiar to English, Scandinavian and German are treated in the articles dealing with these languages. It should be noted that the Frisian dialects agree with English not only in the phenomena enumerated above, but also in a number of changes peculiar to these languages. Such are (1) the change *ā*>*ō* before nasals, *e.g.* A.S. *mōnað*, O.Fr. *mōnath*: O.H.G. *mānod*; (2) the change *ā*>*ǣ* (later *ē*) in other positions, *e.g.* A.S. *rǣd*, O.Fr. *rēd*: O.H.G. *rāt*; (3) the labialization of *a* before nasals, *e.g.* A.S. *mon*, *man*, O.Fr. *mon*, *man*: O.H.G. *man*; (4) the change *a*>*ae* (*e* in Fris.) in close syllables (also in open syllables before front vowels), *e.g.* A.S. *staef*, O.Fr. *stef*: O.H.G. *stap*; (5) the diphthongization of vowels before *h*, *e.g.* A.S. *cneoht*, O.Fr. *kniucht*: O.H.G. *kneht*; (6) the loss of *n* before *þ*, *e.g.* A.S. *ōðer*, O.Fr. *ōther*: O.H.G. *ander*; (7) the palatalization of gutturals before front vowels, *e.g.* A.S. *geldan*, *gieldan* (Engl. *yield*), O.Fr. *ielda*: O.H.G. *geltan*. The noteworthy differences between the two languages in early times seem to have been very few: (1) *a*, *e*, *i*, are diphthongized before *r* followed by a consonant in English, but not in Frisian, *e.g.* A.S. *earm*: O.Fr. *erm* (cf. Goth. *arms*); (2) the diphthong *ai* became *ā* in English everywhere, but in Frisian only in open syllables (*ē* in close syllables); *e.g.* A.S. *āð*: O.Fr. *ēth* (Goth. *aiþs*), but A.S., O.Fr. *āgun* (Goth. *aigun*); (3) the diphthong *au* became (*aeu*, then) *ēa* in English, but *ā* in Frisian, *e.g.* A.S. *ēage* (*ēge*): O.Fr. *āge* (Goth. *augo*); (4) *i* was labialized in Frisian, but not in English, before (original) *w* in the following syllable; *e.g.* O.Fr. *siunga*: A.S. *singan* (cf. Goth. *siggwan*). Frisian texts of the 13th and 14th centuries show many characteristic changes which must have rendered the language almost, if not wholly, unintelligible to an Englishman of the same period; but it is hardly probable that these changes were for the most part of any great antiquity.

Declension.—The I.-Eur. languages seem originally to have had three numbers and eight cases, though it is by no means clear that each of the latter had a distinct form in every class of stems. In Teutonic there is scarcely any trace of the dual in nouns. Of the cases all the early Teutonic languages preserved four, viz. the Nominative, Accusative, Genitive and Dative. The Vocative also was kept in Gothic and the Instrumental to a considerable extent in early German, while the earliest Anglo-Saxon preserved many traces of the locative.

The case endings are best preserved in the earliest Northern inscriptions and in Gothic. As an illustration we may take those of the I.-Eur. *o*-declension:—

	N. sing.	A.	G.	D.	N. plur.	A.	G.	D.
Goth.	*–s*	–	*–is*	*–a*	*–ōs*	*–ans*	*ē*	*–am*
N. inscr.	*–aʒ*	*–a*	*–as*	*–ē*			*–ō*	
cf. Greek	–ος	–ον				–ονς (–ους)	–ων	

As examples of the forms found in the inscriptions may be given N. *erilaz*, A. *staina*, G. *A(n)suʒisalas*, D. *Woduride*. In the other classes of stems also the declension conforms to the general I.-Eur. types. Whatever changes have taken place have usually tended towards simplification; thus there are but few traces of stem-variation (*ablaut*) between different cases of the same noun.

The treatment of adjectives was somewhat more peculiar. In addition to the old type of declension which conformed to that of the demonstrative pronoun and not, as in Greek and Latin, to that of substantives, almost every adjective was inflected also after the model of *n*-stems. This type of inflection occurs chiefly in conjunction with the demonstrative pronoun (definite article) and it is thought that its origin is to be found in substantival (appositional) usage.

Adjectives.

The comparative of adjectives is formed partly by a suffix *-izan-* (*e.g.* Goth. *sutiza*, A.S. *lengra*), which is apparently extended from the suffix *-ios-*, *-is-* found in the other I.-Eur. languages and probably to be compared with Gk. ἡδίων (from *swādisōn*), and partly by a suffix *-ōzan-* (*e.g.* Goth. *swinpoza*) which is peculiar to Teutonic. Similarly the superlative is formed partly by a suffix *-ista-* (*e.g.* Goth. *hauhists*, A.S. *lengest*) corresponding to *-isto-* in other I.-Eur. languages (*e.g.* Gk. ἥδιστος), and partly by a new formation *-ōsta-* (*e.g.* Goth. *armosts*).

Most of the I.-Eur. demonstrative pronouns are found in Teutonic, and the peculiarities of their inflection are in general well preserved. The most important are Goth. *is*, O.H.G. *er*: Lat. *is*; A.S. *he*: Lith. *szis*; Goth. *sa*, *so*, *þata*: Gk. ὁ, ἡ, τό. The last of these (as in Greek) has become a definite article in all except the Scandinavian languages. The interrogative pronouns

Pronouns.

are Goth. *hwas*, A.S. *hwā*: Sanscr. *kas*, and O.H.G. *hwer*: Lat. *quis*. The place of the relative pronoun is supplied by the demonstrative or by indeclinable forms. The inflection of the personal and reflexive pronouns is for the most part peculiar to Teutonic, *e.g.* Goth. 1 sing. N. *ik*, A. *mik*, G. *meina*, D. *mis*; 1 plur. N. *weis*, A.D. *uns* (*unsis*), G. *unsara*. The majority of these forms are common to all the Teutonic languages, though there is a variation between *-e* and *-i* which is probably due to accentual causes; *e.g.* A.S. *ic*, *mec*, *mē*; O.N. *ek*, *mik*, *mer*; O.H.G. *ih*, *mih*, *mir*.

Conjugation.—The Teutonic verb-system is simpler than that of most of the I.-Eur. languages. The old Middle Voice is preserved only in Gothic, where it is used as a passive. In the other Teutonic languages only one or two isolated forms remain. In place of the two old moods, Conjunctive and Optative, there is but one, which is generally called Conjunctive, though its forms are mostly of Optative origin. Again, there are only two tenses, Present and Preterite, the latter of which is derived partly from the I.-Eur. Perfect, partly from Aorist or Imperfect formations. A few old Perfects, however, which have no Presents, retain their original meaning and are generally known as Preterite-presents, *e.g.* Goth. *wait*, A.S. *wāt*, "I know": Gk. οἶδα. In place of the Future the Teutonic languages use either perfective verbs (generally compounded with a preposition) or a periphrasis consisting of the Infinitive with an auxiliary verb.

The conjugation of the Pres. Indic. Act. corresponds in general to that of most of the I.-Eur. languages, *e.g.* Goth. 1 sing. *baira*, 2 *bairis*, 3 *bairiþ*, 1 plur. *bairam*, 2 *bairiþ*, 3 *bairand*, cf. Gk. φέρω, Sanscr. *bharasi*, *bharati*, Gk. φέρομεν, φέρετε, φέροντι (φέρουσι). Gothic had also forms for the 1, 2 dual, *bairos*, *bairats*, which have not been satisfactorily explained. In the other languages there is scarcely any trace of the dual. The conjugation of verbs corresponding to the Greek verbs in -μι is preserved best in Old High German; *e.g.* 1 sing. *habē-m* (*-n*), 2 *habēs*, 3 *habēt*, 1 plur. *habēmēs*, 2 *habēt*, 3 *habēnt*, cf. Gk. 1 sing. τίθημι, Lat. 2 sing. *habēs*, 3 *habet*, 1 plur. *habēmus*, 2 *habētis*, 3 *habent*. A number of archaic forms are preserved in the "verb substantive," *e.g.* Goth. 1 sing. *im*, 2 *is*, 3 *ist*, 3 plur. *sind.*; O.N. 1 plur. *erum*; cf. Gk. 1 sing. εἰμί, 2 ἐσσί, εἶ, 3 ἐστί, 1 plur. ἐσμέν, 3 εἰσί. The forms of the Conjunctive (Optative) correspond in general to those of the other I.-Eur. languages; *e.g.* Goth. 2 sing. *bairais*, 3 sing. *bairai*; Gk. 2 sing. φέροις, 3 sing. φέροι. So also the Imperative, *e.g.* 2 sing. *bair*: Gk. φέρε; but the origin of the 3 sing. and 3 plur. forms in Gothic (*bairadau*, *bairandau*) is not quite clear. The Gothic Passive is conjugated as follows in the Pres. Indic.: 1, 3 sing. *bairada*, 2 sing. *bairaza*, 1, 2, 3 plur. *bairanda*; cf. Gk. 3 sing. φέρεται, 2 sing. φέρῃ (from φέρε(σ)αι), 3 plur. φέρονται.

The Preterite formations are of two types, usually termed "strong" and "weak." The latter belong to verbs whose past participle has a stem *-đa-* (I.-Eur. *-tó-*; see below), the former to the remaining verbs. The singular of the strong Preterite is derived from the I.-Eur. Perfect, while the plural, which in most verbs has a different stem, may come either from the Perfect or from Aorist formations. In the plural the endings were originally accented; hence many verbs show differences not only in the stem vowel but also in the consonants (by Verner's Law, see above) between the two numbers; *e.g.* A.S. sing. *waes*, *wearð*, plur. *wǣron*, *wurdon*. Reduplication is preserved in Gothic only in a limited number of verbs (*e.g.* *haldan*, pret. *haihald*); in the other languages it is rare. The inflection is as follows: Goth. 1 sing. *-bauþ*, 2 *-baust*, 3 *-bauþ*, 1 dual *-budu*, 2 *-buduts*, 1 plur. *-budum*, 2 *-buduþ*, 3 *-budun*; cf. Gk. 1 sing. οἶδα, γέγονα, 2 οἶσθα, 3 οἶδε, γέγονε, 1 plur. ἴσμεν, γέγαμεν. Except in Gothic and Scandinavian the 2 sing. has generally a form (originally Aorist) similar to the plur., *e.g.* A.S. *bude*. The stem of the Conjunctive also agrees with that of the plur., *e.g.* Goth. 1 sing. *-budjau*, 3 sing. *-budi*.

The "weak" Preterite seems originally to have arisen out of a periphrastic formation of which the second part consisted of Imperfect or Aorist forms of the verb seen in A.S. *dōn*, O.H.G. *tuon* (related to Gk. τίθημι), and probably identical with the Pret. A.S. sing. *dede* (*dyde*), plur. *dǣdon*; O.H.G. sing. *teta*, plur. *tātun*. The short reduplication-syllable, however, is lost in the sing., while the long syllable of the plur. (and dual) is preserved only in Gothic. The inflection of the Indic. is as follows:—

sing. Goth. 1 *nasida*, 2 *-des*, 3 *-da*; A.S. *nerede*, *-des*(*t*), *-de*, O.H.G. *nerita*, *-tōs*, *-ta*. O.N. *lagða* (early inscr. *-ō*), *-ir*, *-i*.

plur. 3 Goth. *nasidedun*, A.S. *neredon*; O.H.G. *neritun*; O.N. *lǫgðu*.

It is to be observed that the stem of the weak Preterite almost always conforms to that of the past participle. Such forms as Goth. pret. *waurhta* are probably derived from the past part. *waurhts* (stem *waurhta-*) on the analogy of pret. *nasida* beside past part. *nasiþs* (stem *nasida-*), where the resemblance between the two formations is due to the regular operation of the sound laws.

The inflection of the Conjunctive agrees with that of the strong Preterite, *e.g.* Goth. *nasidedjau*.

The Infinitive is formed from the present stem with an ending *-an* (*e.g.* A.S. *beran*), and probably was originally a case-form of a verbal noun. In the western languages we find also the Dative of a stem *-anja-* used after a preposition; *e.g.* A.S. *to cēosenne*, O.H.G. *zi nemanne*.

The Present Participle has a stem *-and-* (I.-Eur. *-ont-*) identical with the ending of the 3 plur. Indic., as in the other I.-Eur. languages; but the Participles in actual use were declined as *-an-* or *-ja-* stems, *e.g.* G. *bairanda*, A.S. *berende*. The unextended stem survives only in substantives, *e.g.* A.S. *wīgend*, "warriors." The stem of the Past Participle (Passive) is formed by the suffixes *-to-* and *-no-* (Teut. *-da-*, *-na-*), as in the other I.-Eur. languages. The former occurs as a living formation only in connexion with the verbs whose Present stem ends in *-ja-*, *-ō-*, *-ē-* (in Gothic also *-na-*); *e.g.* Goth. *nasiþs*, *salboþs* (: *nasjan*, *salbon*). The Past Participle in use with other classes of verbs has a stem *-ena-* or *-ana-*, the former in English and Scandinavian, the latter in Gothic and German; *e.g.* A.S. *borenn*, O.N. *borinn*, Goth. *baurans*, O.H.G. (*gi*)*boran*. Remains of old Participles in *-to-*, *-no-* formed otherwise than those in living use may be found in adjectives; *e.g.* A.S. (*e*)*ald* : *alan* (cf. Lat. *altus*), *full* : Lat. *pleo* (cf. Lith. *pilnas*).

The above sketch will suffice to show that in regard to morphology the Teutonic group of languages has many characteristic features which distinguish it from other languages of the same stock. On the other hand the morphological differences which exist among the Teutonic languages themselves are on the whole comparatively slight and due mainly to the operation of syncretism and other simplifying processes. In more recent times these processes have been carried still further, so that *e.g.* the Danish verb has lost all inflection of person and number, while distinction of gender has wholly disappeared in English. In the earlier stages of the Teutonic languages differences of phonology are more marked than those of morphology, and afford surer criteria for determining the relations of these languages to one another. It is customary among scholars to classify the whole group in three main divisions, an eastern or Gothic, a northern or Scandinavian, and a western which includes English, Frisian and German. We have noticed above that Gothic began at an early date to show marked divergences from the other languages. The Scandinavian languages also certainly underwent a considerable number of peculiar changes before the beginning of their literatures. But it is to be remembered that from the 6th century to the 9th the Scandinavian peoples were practically cut off from communication with other Teutonic nations by the Slavonic occupation of Mecklenburg and eastern Holstein. The earliest of the more striking sound-changes peculiar to Scandinavian, viz. the loss of initial *j-*, is not thought to have taken place before the 7th century, while the most characteristic features in its morphology, *i.e.* the development of the post-positive article and of the new medio-passive, belong in all probability to a later period. If we confine our attention to changes which probably took place before the middle of the 7th century it will be seen that the English and Frisian languages may fairly be described as lying about midway between Scandinavian and German, though they had already developed well-marked characteristics of their own. They are doubtless to be regarded as the representatives of the old language of the maritime districts, and it is probable that languages of this type were at one time spoken along the whole of the coast between the present frontiers of Belgium and Denmark. On the other hand the special characteristics of German in all probability developed in the interior and those of Scandinavian round the Baltic and the Cattegat. From the 8th century onwards the High German (southern) dialects of German differed greatly from those spoken further north owing to the operation of the changes generally known as the "second sound-shifting." The northern dialects, however (Old Saxon and Low Frankish), were essentially German, though both were more or less affected by Frisian influence.

The Gothic and Scandinavian languages have one or two characteristics in common, the most important of which is the treatment of intervocalic *j* and *w* in a number of words. In the former case we find Goth. *-ddj-* and O.N. *-ggi-*, whereas in German a diphthong developed; *e.g.* Goth. *twaddje* (Gen. of *twai*, "two"), O.N. *tveggia*: O.H.G. *zweio*. In the latter case both Goth. and Scand. had *ggw* (O.N. *ggv*), while a diphthong appears both in English and German, *e.g.* Goth. *triggws* ("true"), O.N. *tryggr*: A.S. *getrīowe*, *getrīewe*, O.H.G. *gitriuwi*. It may also be noted that Gothic and Scandinavian preserved the ending *-t* in the 2 sing. of the strong Preterite, while English and German had a different form with the stem of the plur. (see above). On the ground of these common characteristics some scholars hold that Gothic and Scandinavian are more closely related to one another than to the other Teutonic languages. But, whatever may have been the case originally—and the evidence is far from conclusive—it is clear that by the 4th or 5th century the Scandinavian languages had far more resemblance to English and German than to Gothic.

The languages of the Vandals, Gepidae and other eastern tribes seem to have been practically identical with Gothic. That of the Burgundians, so far as we can judge from the slight evidence at our disposal, had at least as much in common with southern German as with Gothic, which may be due to the fact that this tribe, though originally located in the basin of the Oder, had moved westwards by the 4th century. The early divergence of the eastern languages in general from those of the north and west is perhaps to be ascribed in part to the great extension southwards of the territories of the eastern tribes in the 3rd and 4th centuries. Yet it is not to be overlooked that all dialectical divergences within the Teutonic group seem to be of relatively recent origin, as compared, *e.g.*, with the special characteristics of some of the Greek dialects. Indeed there is scarcely one of them of which we can say with certainty that it dates from before the beginning of our era.

TEUTONIC ORDER, THE, or Teutonic Knights of St Mary's Hospital at Jerusalem (*Der deutsche Orden*, *Deutsche Ritter*) was one of the three great military and religious orders which sprang from the CRUSADES (*q.v.*). Later in birth than the Templars and Hospitallers, the Teutonic Order traces its first beginnings from the third Crusade. Already, indeed, in 1143 we hear of a hospital of Germans at Jerusalem, which Celestine II. places under the control of the Hospitallers, with the stipulation that the prior and servants alone shall necessarily be of German birth.[1] But it is amidst the privations and plague which attended the siege of Acre, during the third Crusade, that the first certain beginnings of the Order appear. In the winter of 1190–91 certain pious merchants from Bremen and Lübeck (towns with which the Order was still to be connected in the days of its later history) laid the foundations of a hospital in a

[1] Röhricht, *Geschichte des Königreichs Jerusalem*, p. 242.

vessel which they had drawn ashore.[1] Within a few years the foundation apparently became attached to the German Church of St Mary the Virgin at Jerusalem; and in March 1198 (there being present in the Holy Land a number of Germans, the relics of Henry VI.'s projected crusade), the great men of the army and the kingdom raised the brethren of the German Hospital of St Mary to the rank of an order of knights. The original members were thus ennobled; and henceforth it was the rule that only Germans of noble birth could join the Order. The Order was from the first, therefore, of a national character, unlike the cosmopolitan orders of the Templars and Hospitallers; but in other respects it was modelled upon the same lines, and shared in the same development. Like the knights of other orders, the Teutonic knights lived a semi-monastic life under the Augustinian rule; and in the same way they admitted priests and half-brothers (*servientes*) into their ranks. Like the other two orders, the Teutonic Order began as a charitable society, developed into a military club, and ended as something of a chartered company, exercising rights of sovereignty on the troubled confines of Christendom. Even in its last phase, the Order did not forget its original purpose: it maintained several great hospitals in its new home on the south-east shore of the Baltic, in addition to an *hôtel des invalides* at Marienburg for its sick or aged brethren.

For a hundred years (1191–1291) the headquarters of the Order were at Acre; nor was it until 1309 that, after a brief sojourn at Venice, the seat of government was transferred to Marienburg on the Vistula. But long before that date the Order had begun to find that its true work lay on the eastern frontiers of Germany. Perhaps it was Hermann von Salza, the first great grand master of the Order (1210–1239), who originally conceived the idea of transplanting the Order to the west. At any rate it was he who accepted the invitation of Andrew of Hungary that the Order should aid him with its resources against the Comans by whom he was threatened. In 1211 the Order received from the king the district of Burzenland in Transylvania. Towns arose and agriculture began to flourish; but seeking to make itself independent, the Order lost its lands, and disappeared from Transylvania. A new opportunity almost immediately arose on the banks of the Vistula. Here Christian, bishop of Prussia, who had received from the Polish duke of Masovia a part of Kulmerland as a fief, had founded the knightly Order of Dobrzin, and was attempting with its aid to subdue the heathens of Prussia. Unsuccessful in his attempt, he invited the Teutonic Order to come to the rescue, and bestowed on the Order Kulm and some of the frontier towns in his territory, with such lands as it should conquer (1228). Thus the Order took its place as the founder of one of the marks on the eastern frontier of Germany, and began to play its part in that *Drang nach Osten*, which is perhaps the vitally important thing in the history of Germany from the 12th to the 14th century. Since the days of Adolf of Holstein and Henry the Lion, a movement of German colonization, in which farmers from the Low Countries, merchants from Lübeck, and monks of the Cistercian Order all played their parts, had been spreading German influence from the Oder to the Vistula, from the Vistula to the Dwina—to Prague, to Gnesen, and even to Novgorod the Great. Of this movement the Teutonic Order became, along with the Hanse, the chosen representative. It was not, indeed, the first knightly Order to gird itself for the task. Besides the knightly Order founded by Christian, there was already another still farther east, which had served as Christian's model, the Knights of the Sword of Livonia. This was an order founded by Albert, 3rd bishop of Riga, in 1201, to serve as an instrument, under his control, for the conquest of the land. But in 1237 the Knights of the Sword were merged into the Teutonic Order, and Livonia became a province of the Order, with a master of its own under the grand master's control, just as, two years before, the Order had also absorbed the Knights of Dobrzin.

[1] Röhricht, *Geschichte des Königreichs Jerusalem*, p. 542. The relations of this new foundation to the German hospital mentioned in 1143 cannot be traced.

In 1229 the Order began the conquest of Prussia, founding fortresses at each step to rivet its conquests (for instance, at Thorn, named after Toron in Palestine), much as the Anglo-Normans had done in their conquest of Wales. Frederic II. gave the Order the rights of a prince of the Empire in its territories: Conrad of Masovia gave it the whole of Kulmerland in 1230; while in 1234 the Order established its independence of all authorities except the Papacy, by surrendering its territories to the Holy See and receiving them back again as a fief. The pope gave to those who joined in the work of the Order the privileges of Crusaders; and the knights, supported by numerous donations and large accessions to their ranks, rapidly increased their territories. By 1260 they ruled the eastern bank of the Vistula from Kulm to its mouth, and the northern shore of the Baltic from the mouth of the Vistula to Königsberg. Livonia they held after 1237; and during the 14th century they gained the Lithuanian territory of Samogitia, which lay between Livonia and their Prussian dominions, while they also added, to the west of the Vistula, Pomerellen and the Neumark (see under PRUSSIA). Already by the beginning of the 14th century these conquests had fundamentally changed the character of the Order. It lost any connexion with the East: after the fall of Acre in 1291, the grand master (whose seat had been at Acre, while the German master (*Deutschmeister*) had controlled the Order in Germany) moved first to Venice, and then, in 1308, to Marienburg on the Vistula. Again, with the accession of large territories, the Order became a governing aristocracy; the original care for the sick, and even the later crusading zeal of the period of conquest, gave way, when conquests were gained and administration was needed, to the problem, half military, half political, of governing a frontier state. The statutes of the Order were altered to suit the new conditions, and a whole system of administration arose. At Marienburg the grand master maintained a magnificent court; round him were the five great dignitaries of the Order, the Grand Commander, the Marshal, the Hospitaller, the Treasurer (*Tressler*) and the Keeper of the Wardrobe (*Trapier*) to see to the clothing of the Order. There was a *Landmeister* for Livonia, and another (the *Deutschmeister*) for the German province, with his seat at Mergentheim in Swabia. Over each of the twenty districts of the Order was set a commander (*Komtur*), with the brethren of his house at his side as advisers. The commander was bound by the advice of his brethren; and in the same way the general chapter of the Order, consisting of the landmeisters and the great dignitaries, formed an advisory board to the grand master in matters such as treaties and internal legislation. It was government by an aristocracy almost Venetian in character. The individual was merged in the Order: each brother must pray four times in the day, and four times at night, and he must at all times pay an unquestioning obedience to his superiors The Order was at once supreme ecclesiastical and political authority. There were no struggles of Church and State in its dominions: the state was also the church: the bishops and the canons of the four bishoprics (with the exception of Ermeland) were priests of the Order. The lay subjects of the Order consisted of two classes; on the one hand there were the conquered Prussians, in a position of serfdom, bound in time of war to serve with the brethren in foreign expeditions; on the other hand there were the German immigrants, both urban and rural, along with the free Prussians who had voluntarily submitted and remained faithful. The towns were large and flourishing; as many as sixty arose in the period between 1233 and 1416, including Thorn and Elbing, Danzig and Königsberg (named after Ottocar of Bohemia, who took part in the campaign during which it was founded). The towns possessed the rights of Magdeburg, or (like Elbing) those of Lübeck; the most important of them soon came to join the Hanseatic League. The Order only imposed customs duties: it levied no tolls within the land; and though its consent was necessary to any change in municipal ordinances, it allowed the towns a large amount of self-government. The concord of the Order with the towns and the Hanse was one great cause of its prosperity until the close of the 14th century; and the rupture of that concord in the 15th century was largely responsible for its fall.

This political and material strength enabled the Order to weather the storm by which the Templars were destroyed at the beginning of the 14th century. For a time, indeed, the Order lay under papal sentence of excommunication; but the transference of his seat to Marienburg at this time (1308) gave the grand master a basis from which he was able to make easy terms with the pope. Nor was the Order, during the 14th century, at all unfaithful to its original calling. Particularly under the grand master Winrich of Kniprode (1351–1382) it was the school of northern chivalry, engaged in unceasing struggle to defend and extend Christianity against the heathen Lithuanian. To the brilliant court of Marienburg, not only a school of chivalry, but under Winrich's predecessor Luther of Brunswick, a literary centre,[1] men came from all over Europe to win their spurs. John of Bohemia had fought by the Vistula: Henry of Bolingbroke was of the goodly company; Chaucer's perfect knight had travelled in "Pruce and Lettowe." The neo-chivalry of the 14th century, in which a fantastic love of adventure had displaced the finer and more ideal motives of the old chivalry, looked towards the Vistula and Marienburg.

At the height of its glory sudden and irretrievable ruin fell upon the Order. The conditions which had made possible its prosperity now disappeared. Externally, a Slavonic reaction came, and dealt heavy blows to the eastward advance of German civilization. The Hussite movement, a victorious expression of Czech nationality, is contemporaneous with the loss of German dominion in Prussia; the exodus of German students from Prague takes place a year before the defeat of the Order at Tannenburg. The particular danger from the Slavs of the north-east arose from the conversion of Lithuania, and the union of converted Lithuania to Poland. The conversion of Lithuania deprived the Order of its mission: the union of Lithuania to Poland robbed it of the security which it enjoyed while they were disunited, and gave new strength to Poland, a constant enemy to the Order which had deprived it of any outlet on the Baltic. Internally, too, the Order suffered. The Hussite wars, the feuds of Burgundian and Armagnac, the renewal of the Hundred Years' War, all prevented it from drawing new blood from the west. But above all it lost touch with its subjects. A religious order, largely composed of immigrants from abroad, could not permanently rule a state which had developed a national feeling of its own; and the native aristocracy, both of the towns and the country, revolted against its dominion. The rebellious elements allied themselves instinctively with the Poles, who thus found the absorption of the greater part of the lands of the Order an easy task. Commercial jealousy aided the process: the Order had alienated the towns by entering into competition with their trade; it had established a monopoly of amber and even, occasionally, of corn; and its agents were spread as far afield as Bruges. This commercial policy had indeed a deeper and more fatal effect than the alienation of the towns; it secularized still further the brethren of the Order, and made them financiers instead of soldiers. Their finances were indeed excellent; they kept regular accounts, and had already developed the modern principle of separating the civil list from the expenses of the government; but when they brought the tables of money-changers into the temple, they were doing as the Templars had done before them, and were likely to suffer as the Templars had suffered.

The first blow struck at the Order, if it did not destroy its power immediately, ruined its prestige for ever. The defeat which the Polish king Ladislaus inflicted upon the knights at Tannenberg in 1410 was crushing. It brought Ladislaus little immediate gain; but it stimulated the elements of unrest in Prussia to fresh activity. The discontented clergy, especially in Livonia; the towns, such as Danzig; the native aristocracy, organized in a league (the *Eidechsenbund*, or League of the Lizard), all sought to use their opportunity. It was in vain that the heroic grand master, Henry of Plauen (1410–1413) sought to stem the tide of disaster; he was deposed by the chapter of the Order for his pains. The success of the Hussite raids in Germany gave fresh confidence to the Slavs of Poland. The Order was at variance within itself; some of the houses of the brethren refused to obey the marshal, and the grand master quarrelled with the German master. Above all, there arose in 1440 the Prussian League (*Preussischer Bund*), in which the nobles and towns joined together, nominally for common protection of their rights, but really against the Order. The League naturally sympathized with Poland, not only because Poland was the enemy of the knights, but also because under Poland it hoped to enjoy the practical liberty which Polish anarchy already seemed to offer. The ultimate result was that in 1454 an embassy of the League offered Prussia to the Polish king, and that, after many years of war, the Peace of Thorn (1466) gave to Poland West Prussia, with Marienburg, Thorn, Danzig and other towns, in full possession, and, while leaving East Prussia to the Order, made the Order the vassals of Poland for the territory which it retained. Henceforth the grand master was to sit in the Polish diet on the left of the king, and half of the knights of the Order were to be Polish.

From 1466 to 1526 grand masters of the Order ruled in East Prussia as vassals of Poland. But the master of the Livonian province and the German master would not obey a Polish vassal, and went their own way; the German master took the grand master's place as a prince of the Empire. The brethren of East Prussia, however, still sighed for independence; and they pursued the policy of choosing German princes to be grand masters of the Order, in the hope of regaining liberty by their aid. Frederick of Saxony held the office from 1498 to 1511; and he was succeeded by the Hohenzollern Albert of Brandenburg-Anspach. When Lutheranism arose, it spread rapidly in Prussia; Albert himself came into contact with Luther, and turning Protestant he secularized his territories, and (1526) made them into an hereditary duchy, still held as a fief of the king of Poland. Few of the brethren resisted; and the Order quietly ceased from the land where for three hundred years it had had its being.

Henceforth the Teutonic Order lived in Germany and in Livonia. The master of the latter province had beaten off an attack of the Russians in 1502, and secured a fifty years' peace. But in 1561 another master followed the example of Albert, and received Courland as an hereditary fief from Poland. Henceforth the Order was confined to Germany alone. The German master—now grand master and German master in one—had his headquarters at Mergentheim in Swabia; the revenues of the states scattered throughout the twelve bailiwicks of Germany sustained him and his Order. The Order, clinging to its rights with the conservatism of an ecclesiastical corporation, still maintained its claims to East Prussia, and pressed them tenaciously even against the electors of Brandenburg themselves, when they inherited the land on the failure of Albert's descendants in 1618. The French Revolution finally deprived the Order of all its estates, and for a while of its existence. In 1801 the bailiwicks to the west of the Rhine were absorbed by France; in 1809 the Order was entirely suppressed, and its lands went to the secular principalities in which they lay. But in 1840 the Order was resuscitated in Austria, where it now exists as a semi-religious knighthood, closely connected with the Habsburgs.

It has remembered its earliest objects, and has of late years engaged during war in the ambulance service. "At the foot of sunny vineyards," says Treitschke, "the house of the Teutonic Order now stands at Botzen; on its door is still emblazoned the black cross—in the middle of the shield of the Habsburg-Lorrainers." Whatever its connexion with the Habsburgs, the Order has its real heirs in the Hohenzollerns of Prussia. When Frederic the Great gained West Prussia by

[1] Every house of the Order had two learned brethren, one learned in the law, one in theology. There were also elementary schools, and municipal foundations in which Latin was taught, in the dominions of the Order.

the first partition of Poland (1772), he was uniting together once more the dominions of the Order, sundered since 1466; and it is the kings of Prussia who have inherited the Order's task of maintaining German influence on the banks of the Vistula.

LITERATURE.—The article is chiefly based on H. von Treitschke's *Das deutsche Ordensland Preussens*, in *Historische und politische Aufsätze*, vol. ii. (Leipzig, 1871), and on J. Loserth, *Geschichte des späteren Mittelalters* (Munich and Berlin, 1903). Loserth gives a bibliography of authorities dealing with the history of the Order on pp. 131, 365 and 567–8. The original evidence is to be found in E. Strehlke, *Tabulae Ordinis Teutonici* (Berlin, 1869), and in *Scriptores rerum Prussicarum* (Leipzig, 1861–1870). J. Voigt has traced the history of the Order previous to 1526 in his *Geschichte Preussens* (Königsberg, 1827–1839), and he has dealt with the organization of the Order, and with its history in Germany from 1525 to 1858, in his *Geschichte des deutschen Ritterorden in seinen zwölf Balleien in Deutschland* (Berlin, 1857–1859). More recent writers are Lohmeier, *Geschichte Ost- und Westpreussens* (Gotha, 1880), and Prutz, *Geschichte Preussens* (Stuttgart, 1900). For monographs on the grand masters, the various territories, and the different epochs in the history of the Order see the references in Loserth's work. (E. BR.)

TEUTONIC PEOPLES, a comprehensive term for those populations of Europe which speak one or other of the various Teutonic languages, viz., the English-speaking inhabitants of the British Isles, the German-speaking inhabitants of Germany, Austria-Hungary and Switzerland, the Flemish-speaking inhabitants of Belgium, the Scandinavian-speaking inhabitants of Sweden and Norway and practically all the inhabitants of Holland and Denmark. To these we have to add small German and Flemish-speaking communities in Italy and France and somewhat larger German and Swedish populations in Russia. Outside Europe we have to include also the very numerous populations in America, Africa, Australasia, &c., which have emigrated from the same countries. The statement that the Teutonic peoples are those which speak Teutonic languages requires a certain amount of qualification on one side. In the British Isles, especially Ireland, there is (in addition to the Celtic-speaking elements) a considerable population which claims Celtic nationality though it uses no language but English; and further all Teutonic communities contain to a greater or less degree certain immigrant (especially Semitic) elements which have adopted the languages of their neighbours. On the other hand there does not appear to be any considerable population anywhere which claims Teutonic nationality without using a Teutonic language. We know indeed that France, Spain, Italy, &c., contained within historical times large populations which were Teutonic both by origin and by language, but these have now been completely absorbed. Similarly, there is no doubt that the inhabitants of England and of the German-speaking regions of the Continent are descended very largely from peoples which two thousand years ago spoke non-Teutonic languages. Yet on the whole the definition given above may be accepted as generally true for the present time.

It is to be observed that the term "Teutonic" is of scholastic and not of popular origin, and this is true also of the other terms ("Germanic," "Gothic," &c.) which are or have been used in the same sense. There is no generic term now in popular use either for the languages or for the peoples, for the reason that their common origin has been forgotten. In Tacitus's time, however, when the area occupied by the Teutonic peoples was, of course, considerably less than now, a consciousness of their relationship to one another was fully retained. He cites native poems which declared that the Inguaeones, Hermiones and Istaeuones—the three main branches of the Germani (see below)—were sprung from three sons of a certain Mannus (perhaps "Man"), who was himself the son of the god Tuisto the son of Earth; and in a Frankish document at least four centuries later we hear again of three brothers named Erminus, Inguo and Istio, from whom many nations were descended. In English documents also we find eponymous national ancestors grouped together in genealogical trees, and there is reason to believe that the common origin of the various Teutonic peoples was remembered to a certain extent until comparatively late in the middle ages.

The linguistic characteristics of the various Teutonic peoples have been dealt with under TEUTONIC LANGUAGES. In regard to physical features they present at the present time very many varieties both of stature and of pigmentation, though on the whole they are probably the tallest and fairest of European peoples. These characteristics are noted by a number of ancient writers in language which seems to show that they must at that time have been at least as pronounced as among any of the present Teutonic peoples. Moreover, the tallness and dolichocephaly which now specially mark the more northern peoples of the group appear very prominently in cemeteries of the migration period in Switzerland and other neighbouring countries. On the whole, however, the skeletons found in German and Scandinavian tombs dating even from the earliest period do not show any very remarkable differences from those of the present day. But whether we are justified in speaking of a Teutonic race in the anthropological sense is at least doubtful, for the most striking characteristics of these peoples occur also to a considerable extent among their eastern and western neighbours, where they can hardly be ascribed altogether to Teutonic admixture. The only result of anthropological investigation which so far can be regarded as definitely established is that the old Teutonic lands in northern Germany, Denmark and southern Sweden have been inhabited by people of the same type since the neolithic age, if not earlier.

The results of investigations in prehistoric archaeology are treated in the articles GERMANY and SCANDINAVIAN CIVILIZATION. As no Teutonic inscriptions are extant from before the 3rd or 4th centuries, it cannot be stated with absolute certainty what types of objects are characteristic of Teutonic civilization in the bronze and earliest iron ages. Yet throughout the bronze age it is possible to trace a fairly well-defined group of antiquities covering the basin of the Elbe, Mecklenburg, Holstein, Jutland, southern Sweden and the islands of the Belt, and archaeologists have conjectured with much probability that these antiquities represent the early civilization of the Teutonic peoples. The civilization was, of course, not wholly of native growth. Strong foreign influence, first Aegean and later Etruscan, can be distinguished; but the types introduced from the south have generally undergone considerable modification and expansion. The somewhat surprising degree of wealth and artistic skill of which many of even the earliest antiquities give evidence is probably to be explained by the importance of the amber trade. Both in eastern and in western Germany the objects found are of somewhat different types and seem to point to a lower standard of civilization. What peoples inhabited these regions can only be conjectured, but there is a certain amount of evidence from place-names—not altogether satisfactory—that the Celtic peoples at one time extended eastwards throughout the basin of the Weser. With the beginning of the iron age (perhaps *c.* 500–400 B.C.) Celtic influence becomes apparent everywhere. By this time, however, the great Celtic movement towards the south-east had probably begun, so that the Teutonic peoples were now cut off from direct communication with the centres of southern civilization.

1. *History*.—The first recognition that the inhabitants of Germany, Holland, &c., were a people distinct from their Celtic neighbours dates from about the middle of the 1st century B.C., when Caesar's conquest of Gaul rendered a knowledge of northern Europe more generally accessible to the Romans. Certain notices relating to individual Teutonic tribes come down from still earlier times. Thus there can be little doubt that the Cimbri (*q.v.*) and their allies, who invaded Illyricum, Gaul and Italy in the last years of the preceding century, were for the most part of Teutonic nationality. The Bastarnae also, who in the 3rd century B.C. invaded and settled in the regions between the Carpathians and the Black Sea, are said by several ancient writers to have been Teutonic by origin, though they had largely intermarried with the native inhabitants. Again, individual travellers from the time of Pytheas onwards had visited Teutonic countries in the north. In none of the early records, however, do we get any clear indication that the

Teutonic peoples were distinguished from the Celts. From the time of Caesar onwards the former were known to the Romans as "Germani," a name of uncertain but probably Gaulish origin. It is said to have been first applied to certain Belgic tribes in the basin of the Meuse, who may formerly have come from beyond the Rhine.

At the beginning of our era the Teutonic peoples stretched from the Rhine to the Vistula. Before Caesar's arrival in Gaul they had advanced beyond the former river, but their further progress in this direction was checked by his campaigns, and, though both banks of the river were occupied by Teutonic tribes throughout the greater part of its course, most of these remained in definite subjection to the Romans. The easternmost Teutonic tribe was probably that of the Goths, in the basin of the Vistula, while the farthest to the south were the Marcomanni and Quadi, in Bohemia and Moravia. These latter districts, however, had been conquered from the Boii, a Celtic people, shortly before the beginning of our era. Towards both the south and west the Teutonic peoples seem to have been pressing the Celts for some considerable time, since we are told that the Helvetii had formerly extended as far as the Main, while another important Celtic tribe, the Volcae Tectosages, had occupied a still more remote position, which it is impossible now to identify. How far the Teutonic peoples extended northwards at this time cannot be determined with certainty, but it is clear that they occupied at least a considerable part of the Scandinavian peninsula.

It has already been mentioned that the Teutonic peoples of this period seem to have been fully conscious of their common origin. What exactly the grouping into Inguaeones, Hermiones and Istaeuones was based upon can only be conjectured, though probably its origin is to be sought rather in religion than in political union. The name of the Hermiones, who are defined as "central" or "interior" peoples, is probably connected with that of the Irminsul, the sacred pillar of the Old Saxons. The Inguaeones again are defined as being "next to the ocean"; but the name can be traced only in Denmark and Sweden, where we find the eponymous hero Ing and the god Yngvi (Frey) respectively. It is likely that the name really belonged only to the peoples of the southern Baltic. Very probably there were many tribes which did not regard themselves as belonging to any of these groups. Tacitus himself records a variant form of the genealogy (see above), according to which Mannus had a larger number of sons, who were regarded as the ancestors of the Suebi, Vandilii, Marsi and others (see SUEBI, VANDALS). In two at least of these cases we hear of sanctuaries which were resorted to by a number of tribes. It is not to be doubted that such religious confederations were favourable to the existence of political unions. Generally speaking, however, each tribe formed a political unit in itself, and the combinations brought together from time to time in the hands of powerful kings were liable to fall to pieces after the first disaster.

For a few years at the beginning of the Christian era the part of Germany which lies west of the Elbe was under Roman government; but after the defeat of Varus (A.D. 9) the Rhine and the Danube formed in general the frontiers of the empire. Roman influence, however, made itself felt both by way of trade and especially by the employment of German soldiers in the auxiliary forces. In the age of national migrations—from the 4th to the 6th century—the territories of the Teutonic peoples were vastly extended, partly by conquest and partly by arrangement with the Romans. These movements began in the east, where we find the Goths ravaging Dacia, Moesia and the coast regions as early as the 3rd century. In the following century the Vandals settled in Pannonia (western Hungary), while the Goths occupied Dacia, which had now been given up by the Romans, and subsequently took possession also of large territories to the south of the lower Danube.

The 5th century was the time of the greatest national movements. In 406–9 the Vandals and other tribes invaded Gaul from the east and subsequently took possession of Spain and north-western Africa. Immediately afterwards the Visigoths invaded Italy and captured Rome; then turning westwards they occupied southern Gaul and Spain. The southern Suebic peoples, the Alamanni and Bavarians, extended their frontiers as far as the Alps probably about the same time. Not much later a considerable portion of northern Gaul fell into the hands of the Franks, and before the middle of the century the eastern part was occupied by the Burgundians. Several of these movements were due, without doubt, to pressure from the Huns, an eastern people who had conquered many Teutonic tribes and established the centre of their power in Hungary. Their empire, however, speedily broke up after the death of their king Attila in 453. The chief events of the latter part of the century were the conquest of the eastern part of Britain by the Angli, the invasion of Italy by the Ostrogoths and the complete subjugation of northern Gaul by the Franks. By this time, with the exception of Brittany and the southern part of the Balkan peninsula, practically the whole of southern and western Europe was under Teutonic government.

It is customary to attribute this great expansion partly to the increasing weakness of the Romans and partly to pressure of population in Germany. Both explanations may contain a certain amount of truth; but there is no doubt that the military strength of the Teutonic nations was far more formidable now than it had been in the time of the early empire. Not only is it clear, both from literary and archaeological evidence, that they were better armed (see below), but also their power was much more concentrated. Thus during the 1st century we hear of about a dozen different tribes in and around the lower part of the basin of the Rhine. In later times, with one or two possible exceptions, these were all included under the general term *Franci*, and by the end of the 5th century all had become subject to one king. Similar processes can be traced elsewhere, *e.g.* among the Alamanni and in the northern kingdoms. Their effect, of course, must have been to provide the kings with greater wealth and with larger permanent bodies of armed men. The motive force towards extension of territories was supplied by military ambition; especially we have to take account of the growth of a warlike spirit in the North, which was constantly driving young warriors to seek their fortunes in the service of continental princes. Where the movement was really of a migratory character it may generally be ascribed to external pressure, in particular from the Huns and the Avars.

The first half of the 6th century saw the subjugation of the Burgundian and Visigothic portions of Gaul by the Franks and the recovery of Africa by the Romans. This latter event was soon followed by the overthrow of the Ostrogothic kingdom; but not many years later Italy was again invaded by the Langobardi (Lombards), the last of the great Teutonic migrations. By this time the extension of Teutonic dominion towards the south and west had brought about its natural sequel in the occupation of the old Teutonic lands in eastern Germany, including even the basin of the Elbe, by Slavonic peoples. Before the end of the century Bohemia also and Lower Austria, together with the whole of the basins of the Drave and the Save, had become Slavonic countries.

The story of the succeeding centuries may briefly be described as in general a process of return to the ethnographical conditions which prevailed before the migration period. The Franks and the Langobardi remained in Gaul and Italy, but they gradually became denationalized and absorbed in the native populations, while in Spain Teutonic nationality came to an end with the overthrow of the Visigothic kingdom by the Moors, if not before. Yet throughout the west and south-west the Teutonic frontier remained from fifty to two hundred miles in advance of its position in Roman times. In south-eastern Europe also the Teutonic elements were swallowed up by the native and Slavonic populations, though a small remnant lingered in the Crimea until probably the 17th century. On the other hand the political consolidation of the various continental Teutonic peoples (apart from the Danes) in the 8th century led to the gradual recovery of eastern Germany together with Lower Austria and the greater part of Styria and Carinthia, though

Bohemia, Moravia and the basins of the Vistula and the Warthe have always remained mainly Slavonic. In the British Isles the Teutonic element, in spite of temporary checks, eventually became dominant everywhere. Lastly, from the very beginning of the 9th century bodies of Scandinavian warriors began to found kingdoms and principalities in all parts of Europe. The settlers, however, were not sufficiently numerous to preserve their nationality, and in almost all cases they were soon absorbed by the populations (Teutonic, Celtic, Latin or Slavonic) which they had conquered. Their settlements in Greenland and Canada likewise came to an end, but Iceland, which was formerly uninhabited, remained a Scandinavian colony. The permanent expansion of the Teutonic peoples outside Europe did not begin till the 16th century.

2. *Form of Government.*—From the evidence at our disposal it is difficult to determine how far the Teutonic peoples were under kingly government in early times. Tacitus speaks of tribes which had kings and tribes which had not, the latter apparently being under a number of *principes*. On nearer examination, however, it appears that kingship was intermittent in some tribes, while in others, which had no kings, we find mention of royal families. All such cases were perhaps peculiar to the western peoples; in the east, north and centre we have no evidence for kingless government. Further, while Tacitus represents the power of Teutonic kings in general, with reference no doubt primarily to the western tribes, as being of the slightest, he states that among the Goths, an eastern people, they had somewhat more authority, while for the Swedes he gives a picture of absolutism. It is quite in harmony with these statements that many Northern and probably all the Anglo-Saxon kingly families traced their origin to the gods. The Swedes, indeed, and some of the eastern peoples seem to have regarded their kings themselves as at least semi-divine (see below, § *Religion*). As the west was the side most open to foreign influence during the Roman period, it is likely that the form of government which prevailed here was less primitive than the other, especially as we know that kingship had by this time died out among the Gauls. In later times we very frequently find a number of "kings," generally belonging to one family, within the same tribe; and it is not improbable that the early *principes* were persons of similar position. The kingless state may therefore have arisen out of kingship through divisions of the royal power or through failure on the part of the leading men to agree on a head acceptable to all. On the other hand the conditions of the migration period were doubtless favourable to monarchical government, and from this time onwards kingship appears to have been universal, except among the Old Saxons and in Iceland.

Kingship.

The *concilium* or tribal assembly figures largely in Tacitus's account of the Germani, and he represents it as the final authority on all matters of first-rate importance. Further, it was here that the *principes* were chosen, serious charges brought against members of the tribe and youths admitted to the rights of warriors. The duties of opening the proceedings and maintaining order belonged not to the king but to the priests, from which we may probably infer that the gathering itself was primarily of a religious character and that it met, as among the Swedes in later times, in the immediate neighbourhood of the tribal sanctuary. Such religious gatherings were no doubt common to all Teutonic peoples in early times, but it may be questioned whether among the eastern and northern tribes they were invested with all the powers ascribed to them by Tacitus. After his time tribal assemblies are seldom mentioned, and though we hear occasionally, both in England and elsewhere, of a concourse of people being present when a king holds court on high days or religious festivals, there is no evidence that such concourses took part in the discussion of state affairs. Indeed, considering the greatly increased size of the kingdoms in later times, it is improbable that they were drawn from any except the immediately adjacent districts. When we hear of deliberations now they are those of the king's council or court, a body consisting partly of members of the royal family and partly of warriors old and young in the personal service of the king. Such bodies of course had always existed (see below) and exercised at all times a powerful influence upon the kings, frequently even forcing them into war against their own wishes. That they appear more prominently now than in earlier times is due to the fact that owing to the increased size of the kingdoms, they had become both more numerous and more wealthy. The principle of representation for the unofficial classes, *i.e.* for those not under the immediate lordship of the king, scarcely begins before the 13th century.

Tribal Assembly.

Of all the institutions of the Teutonic peoples probably none exercised a greater influence on their history than the *comitatus*. From Caesar we learn that it was customary at tribal assemblies for one or other of the chiefs to propose an expedition. He had generally no difficulty in gathering a following, and those who embraced his service were held bound to accompany him to the end, any who drew back being regarded as traitors. Incidents illustrative of this custom are of frequent occurrence in early history and tradition. Moreover, kings and other distinguished persons kept standing bodies of young warriors, an honour to them in time of peace, as Tacitus says, as well as a protection in war. Chiefs of known prowess and liberality attracted large retinues, and their influence within the tribe, and even beyond, increased proportionately. The followers (called by Tacitus *comites*, in England "thegns," among the Franks *antrustiones*, &c.) were expected to remain faithful to their lord even to death; indeed so close was the relationship between the two that it seems to have reckoned as equivalent to that of father and son. According to Tacitus it was regarded as a disgrace for a *comes* to survive his lord, and we know that in later times they frequently shared his exile. Perhaps the most striking instance of such devotion was that displayed at the battle of Strassburg in 357, when the Alamannic king Chonodomarius was taken prisoner by the Romans, and his two hundred *comites* gave themselves up voluntarily to share his captivity. In return for their services the chief was expected to reward his followers with treasure, arms and horses. If he were a king the reward might take the form of a grant of land, or of jurisdiction over a section of the population subject to him—in early times a village, in later, perhaps, a considerable district. Further, since the grantees as a rule naturally sent their sons into the service of their own lords, such grants tended to become hereditary, and in them we have the origin of the baronage of the middle ages. The origin of the earls or counts, on the other hand, is to be found in the governors of large districts (Tacitus's *principes*), who seem at first generally to have been members of the royal family, though later they were drawn from the highest barons.

3. *Social Organization.*—As far back as the time of Tacitus we hear of three social classes, viz. nobles, freemen and freedmen. The same classes are met with in later times, though occasionally one of them disappears, *e.g.* the nobility among the Franks and the freedmen (as a distinct class) in the Anglo-Saxon kingdoms, except Kent. Each of these classes was, to a large extent at least, hereditary and had separate rights and privileges of its own. Among the chief of these must be reckoned the wergeld or "man-price." When homicide took place vengeance was regarded as a sacred duty incumbent on the relatives, and sometimes at least the lord also, of the slain man; but, as in the case of any other injury, compensation could be made by a fixed payment. From the evidence of later custom it is probable that the normal payment for a freeman was a hundred head of cattle. The sums paid for members of the other classes were more variable; for the freedman, however, they were always lower, and for the noble higher, sometimes apparently three or four times as high. Similar gradations occur in the compensations paid for various injuries and insults, in fines and, among some tribes, in the value attached to a man's oath. There is a good deal of uncertainty in regard to both the exact position and the numbers of the nobles and freedmen of Tacitus's age. It is probable, however, that the latter, like

the *liti* or *lati* of later times, consisted not only of manumitted slaves but also of whole communities which had forfeited their liberty through unsuccessful warfare or other causes. In addition to these classes there was also a considerable population of slaves, who had no legal status or wergeld and were regarded as the property of their masters. In general, however, their lot seems to have struck the Romans as favourable, since they were not attached to their masters' households but lived in homes of their own, subject to fixed payments in corn, live stock and clothing.

Groups of family and kindred occupy a prominent position in the accounts of Teutonic society given by Caesar and Tacitus. It was regarded as a universal duty to afford protection to one's kinsmen, to assist them in the redress of wrongs and to exact vengeance or compensation in case of death. Hence to have a numerous kindred was a guarantee of security and influence. The large amounts fixed for the wergelds of nobles and even of freemen were paid no doubt, as in later times, not only by the slayer himself, but by every member of his kindred in proportion to the nearness or remoteness of his relationship; and in like manner they were distributed among the kindred of the slain. The importance of the kindred, however, was not limited to purposes of mutual protection. It appears also in the tenure of land, and according to Tacitus the tribal armies were drawn up by kindreds. As to the nature of these organizations the evidence is not altogether consistent. It is clear that agnatic succession prevailed among the princely families of the Cherusci, and the general account given in the *Germania* seems to imply that this type of organization was normal. On the other hand there are distinct traces of cognation not only in Tacitus's works but also in Northern traditions and more especially in the Salic law. On the whole it seems not unlikely that at the beginning of the Christian era the Teutonic peoples of the continent were in a state of transition from cognatic to agnatic organization.

Marriage.

All the usual forms of marriage were known, including marriage by capture and marriage by purchase. The latter appears most prominently in Kent and among the Old Saxons, Langobardi and Burgundians. In other nations, *e.g.* the Franks, we find the payment of a very small sum, which is often regarded as symbolic and as a relic of real purchase. Yet this explanation is open to question owing to the very early date at which the regulation appears, and to the fact that in the case of widows the sum specified had to be paid to relatives of the widow herself on the female side, and by preference to those of a younger generation. Again, Tacitus states that the presents of arms and oxen given by the bridegroom at marriage were made to the bride herself and not to her guardian, and such appears to have been the case in the North also from early times. It is not certain, therefore, that marriage by purchase was a universal and primitive Teutonic custom. Of the actual ceremonies practised at marriage not very much is known. It was preceded, however, by a formal betrothal and accompanied by a feast. Moreover, even among those peoples with whom purchase prevailed it was customary for the bridegroom to present the bride with a "morning-gift," which in the case of queens and princesses often took the form of considerable estates. There is no doubt that the marriages of heathen times were often of a kind which could not be permitted after the adoption of Christianity. Among these may be mentioned marriages with brothers' widows and stepmothers, the latter especially in England. Polygamy was known, but limited, both in early and late times, to persons of exceptionally high position, while of polyandry there is hardly any trace. Indeed, the sanctity attached to marriage seems to have struck the Romans as remarkable. On the other hand strife between persons connected by marriage appears to have been of extremely frequent occurrence, and no motive plays a more prominent part in Teutonic traditions.

4. *State of Civilization.*—It is a much disputed question whether the Teutonic peoples were really settled agricultural communities at the time when they first came into contact with the Romans, shortly before the beginning of our era. That agriculture of some kind was practised is clear enough from Caesar's account, and Strabo's statement to the contrary must be attributed to ignorance or exaggeration. But Caesar himself seems to have regarded the Germani as essentially pastoral peoples and their agriculture as of quite secondary importance, while from Tacitus we gather that even in his time it was of a somewhat primitive character. For not only was the husbandry co-operative, as in much later times, but apparently the ploughlands were changed from year to year without any recognition of a two-course or three-course system. Caesar, moreover, says that the clans or kindreds to whom the lands were allotted changed their abodes also from year to year—a statement which gives a certain amount of colour to Strabo's description of the Germani as quasi-nomadic. Yet there is good reason for believing that this representation of early Teutonic life was by no means universally true. We have evidence, both archaeological and linguistic, that the cultivation of cereals in Teutonic lands goes back to a very remote period, while the antiquity even of the ox-plough is attested by the rock-carvings at Tegneby in Bohuslän (Sweden), which are believed to date from early in the bronze age. Further, that the tribes were not normally of a migratory character, as Strabo seems to imply, is shown by the existence of sanctuaries of immemorial age and by frontier ramparts such as that raised by the Angrivarii against the Cherusci. It would seem that Julius Caesar encountered the Germani under somewhat abnormal conditions. Several of the tribes with which he came into collision had been expelled from their own territories by other tribes, and we are expressly told that Ariovistus's troops had not entered a house for fourteen years. Further, there is satisfactory evidence that the basin of the Rhine, perhaps also a considerable area beyond, had been conquered from Celtic peoples not very long before—from which it is probable that western Germany was still in a more or less unsettled condition. Indeed Caesar himself seems to have regarded the prevalence of the military spirit as the chief hindrance to the development of agriculture. From this time onwards it was from the west mainly that Roman civilization made its way into Germany; but in earlier ages, as we have already noticed, there are more abundant traces of civilization in the basin of the Elbe than in the districts farther to the west. Hence it is not so surprising as might at first sight appear that the remote Aestii, a non-Teutonic people settled about the mouth of the Vistula, are represented by Tacitus as keener agriculturists than any of the other inhabitants of Germany.

All ancient writers emphasize the essentially warlike character of the Germani. Yet Tacitus seems to represent their military equipment as being of a somewhat primitive type. Swords, helmets and coats of mail, he says, were seldom to be seen; in general they were armed only with huge shields, unwieldy spears and darts. Here again he appears to be thinking of the western tribes; for elsewhere he states that some of the eastern peoples were armed with short swords and round shields—which probably were of comparatively small size, like those used in later times. This latter type of equipment prevailed also in the North, as may be seen, *e.g.* from the figures of warriors on the inscribed golden horn found at Gallehus (Jutland) in 1734. The favourite method of attack was by a wedge formation (known later in the North as *svínfylking*), the point being formed by a chosen band of young warriors. Certain tribes, such as the Tencteri, were famous for their horsemen, but the Germani in general preferred to fight on foot. Sometimes also we hear of specially trained forces in which the two arms were combined. Naval warfare is seldom mentioned. The art of sailing seems to have been unknown, and it is probable that down to the 3rd century the only peoples which could truly be described as seafaring were those of the Baltic and the Cattegat.

There is no doubt that Roman influence brought about a considerable advance in civilization during the early centuries of our era. The cultivation of vegetables and fruit trees seems to have been practically unknown before this period, and almost all their names testify to the source from which they were derived. We may notice also the introduction of the mill in place of the quern which hitherto had been in universal use. In all such cases the tribes subject to the Romans, in the neighbourhood of the Rhine, were probably the chief channel by which Roman influence made its way, though account must also be taken of the fact that considerable numbers of warriors from remoter districts were attracted to serve in the Roman armies. Great improvements took place likewise in armour and weapons; the equipment of the warriors whose relics have been found in the Schleswig bog-deposits, dating from the 4th and 5th centuries, appears to have been vastly superior to that which Tacitus represents as normal among the Germani of his day. Yet the types, both in armour and dress, remained essentially Teutonic—or rather Celtic-Teutonic. Indeed, when in the course of time uniformity came to prevail over the greater part of Europe, it was the Teutonic rather than the Roman fashions which were generalized.

Writing. The antiquity of the art of writing among the Teutonic peoples is a question which has been much debated. Tacitus says that certain marks were inscribed on the divining chips, but it cannot be determined with certainty whether these were really letters or not. The national type of writing, generally known as Runic, must have been fully developed by the 4th century, when some of its letters were borrowed by Ulfilas (Wulfila) for his new alphabet (see GOTHS: § C.). Indeed, by this time it was probably known to most of the Teutonic peoples, for several of the inscriptions found in Jutland and the islands of the Belt can hardly be of later date. As to the source from which it was derived opinions still differ, some thinking that it was borrowed from the Romans a century or two before this time, while others place its origin much farther back and trace it to one of the ancient Greek alphabets. Many of the earliest inscriptions read from right to left, and the *βουστροφηδόν* type is also met with occasionally. It is clear both from literary and linguistic evidence that the character was chiefly used for writing on wood, but the inscriptions which have survived are naturally for the most part on metal objects—in Sweden, Norway and England also on monumental stones. In Germany very few Runic inscriptions have been found, and there is nothing to show that the alphabet was used after the 8th century. In England also it seems not to have lasted much longer, but inscriptions are far more numerous. On the other hand, in Scandinavian countries it continued in use through the greater part of the middle ages—in Gotland till the 16th century; indeed, the knowledge of it seems never to have wholly died out. In the course of time, however, it underwent many changes, and the earliest inscriptions must have been unintelligible for over a thousand years until they were deciphered by scholars within the last half century. The Roman alphabet first came into use among the western and northern Teutonic peoples after their adoption of Christianity.

5. *Funeral Customs.*—Icelandic writers of the 12th and 13th centuries distinguished between an earlier "age of burning" and a later "age of barrows," and the investigations of modern archaeologists have tended in general to confirm the distinction, though they have revealed also the burial-places of times antecedent to the age of burning. Throughout the stone age inhumation appears to have been universal, many of the neolithic tombs being chambers of considerable size and constructed with massive blocks of stone. Cremation makes its appearance first in the earlier part of the bronze age, and in the latter part of that age practically displaces the older rite. In the early iron age there is less uniformity, some districts apparently favouring cremation and others inhumation. The former practice is the one recognized by Tacitus. In the national migration period, however, it fell into disuse among most of the continental Teutonic peoples, even before their conversion, though it seems to have been still practised by the Heruli in the 5th century and by the Old Saxons probably till a much later period. It came into Britain with the Anglo-Saxon invaders and continued in use in certain districts perhaps until nearly the close of the 6th century. In Scandinavian lands the change noted by Icelandic writers may be dated about the 5th and 6th centuries, though inhumation was certainly not altogether unknown before that time. After the 6th century cremation seems not to have been common, if we may trust the sagas, but isolated instances occur as late as the 10th century. It is to be observed that cremation and the use of the barrow are not mutually exclusive, for cremated remains, generally in urns, are often found in barrows. On the other hand inhumation below the surface of the ground, without perceptible trace of a barrow, seems to have been the most usual practice during the national migration period, both in England and on the continent. A special form of funeral rite peculiar to the North was that of cremation on a ship. Generally the ship was drawn up on land; but occasionally we hear, in legendary sagas, of the burning ship being sent out to sea. Large ships containing human remains have sometimes been found in barrows of the viking age. Arms and ornaments are frequently met with, sometimes also horses and human remains which may be those of slaves, the belief being that the dead would have all that was buried with him at his service in the life beyond. Usage, however, seems to have varied a good deal in this respect at different times and in different districts.

6. *Religion.*—The conversion of the Teutonic peoples to Christianity was a gradual process, covering some seven centuries. The first to accept the new religion seem to have been the Goths, beginning about the middle of the 4th century, and the Vandals must have followed their example very quickly. In the course of the 5th century it spread to several other nations, including the Gepidae, Burgundians, Rugii and Langobardi. In all these cases the Arian form of Christianity was the one first adopted. The first conversion to the Catholic form was that of the Franks at the end of the 5th century. The extension of Frankish supremacy over the neighbouring Teutonic peoples brought about the adoption of Christianity by them also, partly under compulsion, the last to be converted being the Old Saxons, in the latter half of the 8th century. The conversion of England began in 597 and was complete in less than a century. In the north, after several attempts during the 9th century which met with only temporary success, Christianity was established in Denmark under Harold Bluetooth, about 940–960, and in Norway and Sweden before the end of the century, while in Iceland it obtained public recognition in the year 1000. Many districts in Norway, however, remained heathen until the reign of St Olaf (1014–1028), and in Sweden for half a century later.

The subsequent religious history of the various Teutonic peoples will be found elsewhere. Here we are concerned only with the beliefs and forms of worship which prevailed before the adoption of Christianity. For our knowledge of this subject we are indebted chiefly to Icelandic literary men of the 12th and 13th centuries, who gave accounts of many legends which had come down to them by oral tradition, besides committing to writing a number of ancient poems. Unfortunately Icelandic history is quite unique in this respect. In the literatures of other Teutonic countries we have only occasional references to the religious rites of heathen times, and these are generally in no way comparable to the detailed accounts given in Icelandic writings. Hence it is often difficult to decide whether a given rite or legend which is mentioned only in Icelandic literature was really peculiar to that country alone or to the North generally, or whether it was once the common property of all Teutonic peoples.

A number of gods were certainly known both in England and among many, if not all, the Teutonic peoples of the continent, as well as in the North. Among these were Odin (Woden), Thor (Thunor) and Týr (Ti); so also Frigg (Frig), the wife of Odin (see FRIGG, ODIN, WODEN, THOR, TÝR). Some scholars have thought that Balder, the son of Odin, was once known in Germany, but the evidence is at least doubtful. Heimdallr, the watchman of the gods and Ullr, the stepson of Thor, as well as Hoenir, Bragi and most of the other less prominent gods.

were also probably peculiar to the North, though Ullr at least was known in Denmark. Some of these deities may originally have been quite local. Indeed, such may very well have been the case with Frey, the chief god of the North after Thor and Odin. Tradition at all events uniformly points to Upsala as the original home of his cult. But it is probable that both he and his sister Freyia were really specialized forms of a divinity which had once been more widely known. Their father, Niörðr, the god of wealth, who is a somewhat less important figure, corresponds in name to the goddess Nerthus (Hertha), who in ancient times was worshipped by a number of tribes, including the Angli, round the coasts of the southern Baltic. Tacitus describes her as "Mother Earth," and the account which he gives of her cult bears a somewhat remarkable resemblance to the ceremonies associated in later times with Frey. This family of deities were collectively known as Vanir, and are said to have once been hostile to the Aesir, to whom Odin belonged. Their worship was generally connected with peace and plenty, just as that of Odin was chiefly bound up with war. Gefion was another goddess who may represent a later form of Nerthus. In her case tradition points distinctly to a connexion with Denmark (Sjaelland). On the other hand, the portraiture of Skaði, the wife of Niörðr, seems to point to a Finnish or Lappish origin. The rest of the northern goddesses are comparatively unimportant, and only one of them, Fulla, the handmaid of Frigg, seems to have been known on the continent.

Some of the deities known to us from German and English sources seem also to have been of a local or tribal character. Such doubtless was Fosite, to whom Heligoland was sacred. Saxnot (Seaxneat), from whom the kings of Essex claimed descent, was probably a god of the Saxons. Holda, who is known only from the folklore of later times, appears to have been a German counterpart of Nerthus. Ing, who is connected with Denmark in Anglo-Saxon tradition, was in all probability the eponymous ancestor of the Inguaeones (see above). His name connects him, too, with the god Frey, who was also called Yngvifreyr and Ingunarfreyr, and he must at one time have been closely associated with Nerthus. The relationship of Ing to the Inguaeones is paralleled by that of Irmin to the Hermiones (see above). He may be the deity whom Tacitus called "Hercules."

Some of these eponymous ancestors may be regarded as heroes rather than gods, and classed with such persons, as Skiöldr, the eponymous ancestor of the Danish royal family, who is not generally included in the Northern pantheon. But the line of division between the human and the divine is not very definite. The royal family of Norway claimed descent from Frey, and many royal families, both English and Northern, from Woden (Odin). Indeed, several legendary kings are described as sons of the latter. Sometimes, again, the relationship is of a conjugal character. Skiöldr, though hardly a god himself, is the husband of the goddess Gefion. So we find Freyia's priest described as her husband and Frey's priestess as his wife, and there is no reason for regarding such cases as exceptional.

If it is not always easy to distinguish between gods and heroes, there is still greater difficulty in drawing a line between the former and other classes of supernatural beings, such as the "giants" (O.N. *iötnar*, A.S. *eotenas*). Here again we have intermarriage. Skaði, the wife of Niörðr, and Gerðr, the wife of Frey, were the daughters of the giants Thiazi and Gymir respectively, though Skaði is always reckoned as a goddess. Loki also was of giant birth; but he is always reckoned among the gods, and we find him constantly in their company, in spite of his malevolent disposition. In general it may be said that the giants were regarded as hostile to both gods and men. Often they are represented as living a primitive life in caves and desolate places, and their character is usually ferocious. But there are exceptions even among the male giants, such as Aegir, whom we find on friendly terms with the gods. It is worth noting also that some of the leading families of Norway are said to have claimed descent from giants, especially from Thrymr, the chief opponent of Thor. In such cases there may be some connexion between the giants and the semi-civilized (Finnish or Lappish) communities of the mountainous districts. This connexion is more clear in the case of Thórgerðr Hölgabrúðr, who is known chiefly from the extreme veneration paid to her by Haakon, earl of Lade (+995). According to one story she was the daughter of Hölgi, the eponymous king of Halogaland (northern Norway); according to another she was the wife of Hölgi and daughter of Gusi, king of the Fins. She ought perhaps to be regarded rather as a goddess than as a giantess, but she is never associated with the other deities.

Another class of supernatural beings was that of the dwarfs. They were distinguished chiefly for their cunning and for skill in working metals. More important than these from a religious point of view were the elves (O.N. *alfar*, A.S. *ylfe*), who certainly received worship, at all events in the North. They are almost always spoken of collectively and generally represented as beneficent. In some respects, *e.g.* in the fact that they are often said to inhabit barrows, they seem to be connected with the souls of the dead. In other cases, however, they are hardly to be distinguished from spirits (the Icel. *landvaettir*, &c.), which may be regarded as *genii locorum*.

In addition to the above there were yet other classes of supernatural beings (see NORNS and VALKYRIES). Mention, however, must be made here of the *fylgiur* and *hamingiur* of Northern belief. These are of two kinds, though the names seem not always to be clearly distinguished. Sometimes the *fylgia* is represented as a kind of attendant spirit, belonging to each individual person. It may be seen, generally in animal form, in visions or by persons of second sight, but to see one's own *fylgia* is a sign of impending death. In other cases the *fylgiur* (or perhaps more correctly the *hamingiur*) apparently belong to the whole family. These generally appear in the form of maidens.

Human beings, especially kings and other distinguished persons, were not infrequently honoured with worship after death. In Sweden during the 9th century we have trustworthy record of the formal deification of a dead king and of the erection of a temple in his honour. In general the dead were believed to retain their faculties to a certain extent in or near the place where they were buried, and stories are told of the resistance offered by them to tomb-robbers. It would seem, moreover, that they were credited with the power of helping their friends (and likewise of injuring other people) very much in the same way as they had done in life. Hence the possession of the remains of a chief who had been both popular and prosperous was regarded as highly desirable.

The blessings which kings were expected to bestow upon their subjects, in life as well as after death, were partly of a supernatural character. Chief among them was that of securing the fertility of the crops. The prevalence of famine among the Swedes was attributed to the king's remissness in performing sacrificial functions; and on more than one occasion kings are said to have been put to death for this reason. Under similar circumstances Burgundian kings were deposed. In connexion with this attribution of superhuman powers, we may mention also the widespread belief that certain persons had the faculty of "changing shape," and especially of assuming the forms of animals.

Besides the various classes of beings to the worship of which we have already referred, we hear occasionally also of sacred animals. Tacitus tells of horses consecrated to the service of the gods, and of omens drawn from them, and we meet again with such horses in Norway nearly a thousand years later. In the same country we find the legend of a king who worshipped a cow. Besides the anthropomorphic "giants," mentioned above, Northern mythology speaks also of theriomorphic demons, the chief of which were Midgarðsormr, the "world-serpent," and Fenrisulfr, a monster wolf, the enemies of Thor and Odin respectively. These beings are doubtless due in part to poetic imagination, but underlying this there may be a substratum of primitive religious belief. In contrast with later Scandinavian usage Tacitus states that the ancient Germans had no images of the gods. But he does speak of certain sacred symbols which he defines elsewhere as figures of wild beasts. One of the chief objects of veneration among the Cimbri is said to have been a brazen bull.

Figures of animals, however, were not the only inanimate things regarded in this way. The Quadi are said to have considered their swords divine. More important than this was the worship paid, especially in the North, to rocks and stone cairns, while springs and pools also were frequently regarded as sacred in all Teutonic lands. But, on the whole, there is perhaps no characteristic of Teutonic religion, both in early and later times, more prominent than the sanctity attached to certain trees and groves, though it is true that in such cases there is often a doubt as to whether the tree itself was worshipped or whether it was regarded as the abode of a god or spirit. The sanctuaries mentioned by Tacitus seem always to have been groves, and in later times we have references to such places in all Teutonic lands. One of the most famous was that in or beside which stood the great temple of Upsala. Here also must be mentioned the Swedish Vårdträd or "guardian tree," which down to our own time is supposed to grant protection and prosperity to the household to which it belongs. One of the most striking conceptions of Northern mythology is that of the "world-tree," Yggdrasil's Ash, which sheltered all living beings (see Yggdrasil). The description given of it recalls in many respects that of a particularly holy tree which stood beside the temple at Upsala. For the idea we may compare the Irminsul, a great wooden pillar which appears to have been the chief object of worship among the Old Saxons, and which is described as "universalis columna quasi sustinens omnia."

The Northern sanctuaries of later times were generally buildings constructed of wood or other materials. A space apparently partitioned off contained figures of Thor or Frey and perhaps other gods, together with an altar on which burned a perpetual fire. In the main body of the temple were held the sacrificial feasts. The presiding priest seems always to have been the chief to whom the temple belonged, for there is no evidence for the existence of a special priestly class in the North. In England, however, the case was otherwise; we are told that the priests were never allowed to bear arms. There is record also of priests among the Burgundians and Goths, while in Tacitus's time they appear to have held a very prominent position in German society. Among all Teutonic peoples from the time of the Cimbri onwards we frequently hear also of holy women whose duties were concerned chiefly with divination. Sometimes, indeed, as in the case of Veleda, a prophetess of the Bructeri, during Vespasian's reign, they were regarded practically as deities. After the adoption of Christianity, and possibly to a certain extent even before, such persons came to be regarded with disfavour—whence the persecutions for witchcraft—but it is clear from Tacitus's works and other sources that their influence in early times must have been very great. In the North the sanctuaries called *hörgar* seem to have been usually under the charge of the wives and daughters of the household. But there is some evidence also for the existence of special priestesses at certain sanctuaries.

Of religious ceremonies the most important was sacrifice. The victims were of various kinds. Those offered to Odin (Woden) were generally, if not always, men, from the time of Tacitus onwards. Human sacrifices to Thor and the other gods are not often mentioned. Of animals, which were consumed at the sacrificial banquets, we hear chiefly of horses, but also of oxen and boars. At human sacrifices, however, dogs and hawks were often offered with the men. At all sacrifices it seems to have been customary to practise divination; in connexion with human sacrifice we have record of this rite from the time of the Cimbri. One barbarous custom which was regarded as a sacrifice was the dedication of an enemy's army to the gods, especially Odin. This custom, which is likewise known to have prevailed from the earliest times, involved the total destruction of the defeated army, together with everything belonging to them. In general the chief sacrificial festivals seem to have taken place at fixed times in the year, one in early or mid-autumn, another at mid-winter and a third during the spring. Sacrifices on an exceptionally large scale were held at Upsala and Leire every nine years, at the former place about the time of the spring equinox, at the latter in the early part of January. Besides these fixed festivals sacrifices could of course be offered in all time of public or private need. In the latter case resort was very frequently had also to sorcery and necromancy.

Mention has been made above of the belief that the dead retained a conscious existence in or near the place where they were buried, and that they were able to confer blessings upon their friends. Beside this belief, however, we find another which seems hardly to be compatible with it, viz., that the souls of the dead passed to the realm of Hel, who in Northern mythology is represented as the daughter of Loki. Again, those who had fallen in battle were supposed to go to Valhalla, where they became warriors in Odin's service. This last belief seems to have been connected at one time with the practice of cremation. In conclusion it must be mentioned that even the life of the gods was not to be for ever. A day was to come when Odin and Thor would fall in conflict with the wolf and the world-serpent, when the abode of the gods would be destroyed by fire and the earth sink into the sea. But the destruction was not to be final; in the future the gods of a younger generation would govern a better world. How far these beliefs were common to the Teutonic peoples as a whole cannot be determined with certainty. Some scholars hold that they were peculiar to the mythology of Norway and Iceland and that they arose at a late period, largely through Christian influence. But a serious objection to this view is presented by the fact that very similar ideas in some respects were current among the ancient Gauls.

Authorities.—I. *Ancient.* The most important of the early authorities (down to the 2nd century) are Caesar (esp. *B. Gall.* i. 31–54, iv. 1–19, vi. 21–24), Strabo (esp. p. 290 ff.), Pliny, *Hist. Nat.* (esp. iv. 96 ff., xvi. 1 ff., xxxvii. 42 ff.), Tacitus (esp. *Germania*), Plutarch, *Marius*, and Ptolemy, *Geogr.* ii. 11. Among later writers much valuable information is given by Ammianus Marcellinus, Jordanes, Procopius, Gregory of Tours, Bede, Paulus Diaconus, Widukind, Thietmar, Adam of Bremen and Saxo Grammaticus, as well as by the early laws and charters. To these must be added a large number of Old Norse writings including the older Edda and the prose Edda (the chief authorities for Northern mythology), Islands Landnámabók and many sagas dealing with the history of families in Iceland (such as Eyrbyggia Saga) or with the lives of Norwegian and other kings, both historical and legendary (in Heimskringla, Fornmanna Sögur and Rafn's Fornaldar Sögur Norrlanda). For further references see Britain (Anglo-Saxon), Germany (Ethnography and Early History), and Scandinavian Civilization.

TEVIOT, ANDREW RUTHERFORD, Earl of (d. 1664), was the son of William Rutherford of Quarrelholes, Roxburghshire. His education was received in Edinburgh, and he took up the career of soldier of fortune. His services were given to the French government, which maintained regiments of Scottish mercenaries. On the restoration of Charles II., Rutherford was taken into employment by his own king on the recommendation of Louis XIV. of France. He had held a commission as lieutenant-general in France and had a high reputation for personal courage. Charles II. gave him the Scottish title of Lord Rutherford and the governorship of Dunkirk, which had been acquired by the Protector Oliver Cromwell. When Charles II. sold the town to France in 1662 Rutherford was consoled by the command of the 2nd or Tangier regiment, was made earl of Teviot in the peerage of Scotland, and was sent in 1663 as governor to Tangier. His tenure of office was very short, for on the 4th of May 1664 he allowed himself to be entrapped into an ambush by the Moors, who carried on incessant irregular warfare against the English garrison, and was killed, together with nineteen officers and nearly five hundred men of his garrison.

See W. F. Lord, *The Lost Possessions of England* (London, 1896).

TEVIOTDALE, the valley of the Teviot, Roxburghshire, Scotland. In a limited sense the word describes the stretch above Hawick (9 m.) and, in a wider sense, the whole vale, extending in a north-easterly direction from Teviothead nearly to the confines of the parish of Roxburgh, a distance of 23 m. It is sometimes incorrectly used as an alternative name for the shire, much of the area of which, in point of fact, lies outside the Teviot drainage basin. There are numerous points of interest in the dale. Henry Scott Riddell (1798–1870), the poet, was buried at Teviothead. Almost side by side in the churchyard are the obelisk near his grave and the memorial stone erected in the cemetery wall to John Armstrong of Gilnockie, the celebrated freebooter, who, along with several followers, was treacherously seized in 1530 and hanged at Caerlanrigg, in the immediate vicinity, by order of James V. Riddell is further commemorated by a monument on Dryden hill. Branxholm tower, the peel of Goldielands, and Harden castle (on Harden burn, a tributary of Northwick water) are spots familiar through the writings of Sir Walter Scott and many Border ballads. Five m. to the east of Hawick stands the hill of Ruberslaw (1392 ft.). Among the crags on its summit is the rock, still called "Peden's chair," from which Alexander Peden preached to conventicles of Covenanters. Below Hawick interest principally centres around Minto, Hassendean—the Hazeldean of Sir Walter Scott's song, "Jock o' Hazeldean"—and Ancrum.

TEWFIK PASHA (1852–1892), khedive of Egypt, son of the Khedive Ismail, was born on the 15th of November 1852. His mother was a fellah woman. Although the eldest son, he was not sent to Europe to be educated, like his younger brothers, but was left to grow up in his native country. In 1866 Ismail succeeded in his endeavour to alter the order of succession to the khediviate. The title, instead of passing to the eldest living male descendant of Mehemet Ali, was now to descend from father to son. Ismail sought this alteration mainly because he disliked his uncle, Halim Pasha, who was his heir-presumptive, and he is supposed to have imagined that he would be able to select whichever of his sons he pleased for his successor. But he found, after the change had been made, that the powers interpreted the new arrangement as applying strictly to the eldest son. Tewfik therefore became heir-apparent. He was given a palace near Cairo to live in, and for twelve years he passed an uneventful life, farming, and establishing a reputation for good sense and fair dealing with his fellah tenants. In 1878 he was appointed president of the council after the dismissal of Nubar Pasha. He held this office only for a few months; but this was long enough to show that, if he was unambitious and not particularly intelligent or energetic, he had the wisdom to refrain from taking a part in the intrigues which then formed the chief part of political life in Egypt. He went back to his estate, and settled down once more to a quiet country life. He was not left undisturbed for long. On the 26th of June 1879 Ismail, at the instance of Great Britain and France, was deposed by the sultan, who sent orders at the same time that Tewfik should be proclaimed khedive. The new viceroy was so little pleased by the news of his accession that he soundly boxed the ears of the servant who first brought the tidings to him. Egypt at that time was involved in financial and political troubles brought about by the policy of Ismail (*q.v.*), and the situation was made worse by the inaction of England and France for some months following Tewfik's accession. Tewfik's people were dissatisfied, his army disaffected; his advisers were nearly all of the adventurer class, with their own ends to gain; and he himself had neither the character of a strong ruler nor the experience that would have enabled him to secure an orderly administration of affairs. Disorder prevailed until November 1879, when the dual control was re-established by the governments of Great Britain and France. For over two years Major Baring (afterwards Lord Cromer), Mr (afterwards Sir) Auckland Colvin, and M. de Blignières practically governed the country, endeavouring to institute reforms while possessing no means of coercion. During all this time the disaffection in the Egyptian army was increasing. Tewfik has been blamed for his failure to take a firm line with the rebels, but his attitude was governed by his relations with Great Britain and France, and he was unable to control events. The dissatisfaction culminated in the anti-foreign movement headed by Arabi Pasha (*q.v.*), who had gained complete command of the army. In July 1882 the attitude of Arabi, who was carrying out defensive works on a large scale, made it necessary for the British admiral (Sir Beauchamp Seymour, afterwards Lord Alcester) to declare that he would bombard the forts of Alexandria unless they were handed over to him. Before the bombardment began it was suggested to Tewfik that he should leave the city and embark either upon a man-of-war belonging to one of the neutral powers, or in his own yacht, or in a mail steamer which was then in the port. His answer was, "I am still khedive, and I remain with my people in the hour of their danger." At his palace of Ramleh, 3 m. from the town, he was beyond reach of the shells, but his life was nevertheless imperilled. When the rebel soldiers attacked the palace he managed to make his escape and to reach another palace after passing through the burning streets of Alexandria. Here he was obliged to agree that a guard of British bluejackets should protect him from further risk. He showed his courage equally during the cholera epidemic at Alexandria in 1883. He had gone back to Cairo after the battle of Tel-el-Kebir, had consented to the reforms insisted upon by Great Britain, and had assumed the position of a constitutional ruler under the guidance of Lord Dufferin, the British special commissioner. When the cholera broke out, he insisted upon going to Alexandria. His wife accompanied him, and he went round the hospitals, setting an excellent example to the authorities of the city, and encouraging the patients by kind and hopeful words. In 1884 Sir Evelyn Baring went back to Egypt as diplomatic agent and consul-general of Great Britain. His first task was to demand that Tewfik should abandon the Sudan. Tewfik gave his consent with natural reluctance, but, having consented, he did everything he could to ensure the success of the policy which Baring had been sent to carry out. He behaved with equal propriety during the negotiations between Sir H. Drummond Wolff and the Turkish envoy, Mukhtar Pasha, in 1886. His position was not a dignified one—that of a titular ruler compelled to stand by while others discussed and managed the affairs of his country. The sultan was his suzerain; in Great Britain he recognized his protector: to the representative of each he endeavoured to show friendliness and esteem. As time went on his confidence in Baring increased, until at last he deferred to the British agent in almost everything. On occasion, however, he acted on his own initiative, as when in June 1888 he dismissed Nubar Pasha and summoned Riaz Pasha to form a ministry—an action influenced, nevertheless, by Tewfik's knowledge of the divergence of views between Nubar and the British agent. Baring encouraged Tewfik to show his activity in matters of administration, and he took a great interest in all matters connected with irrigation, education and justice. He was not a particularly strong man either in mind or in character, but he showed a genuine desire to govern his country for its own benefit. He understood the importance to Egypt of British assistance and support; his natural shrewdness made him accept the British conditions; his natural good feeling kept him from any inclination to intrigue. In private life he was courteous and amiable. He had no desire to keep up the unapproachable state of an oriental ruler. Indeed, in many ways his manners and habits were less oriental than European. He married in 1873 his kinswoman, Amina Hanem, with whom he lived very happily. She was his only wife and Tewfik was a strong advocate of monogamy. He died on the 7th to January 1892, at the Heluan palace near Cairo, and was succeeded by his eldest son, Abbas II. (*q.v.*).

A warm tribute to Tewfik's many admirable qualities was paid by Baring (Lord Cromer) in his report on the administration of Egypt for 1891 (see *Egypt*, No. 3, 1892, pp. 1 and 2).

TEWKESBURY, a market town and municipal borough in the Tewkesbury parliamentary division of Gloucestershire, England, 15½ m. N.E. of Gloucester by the Midland railway. Pop. (1901) 5419. It lies in a flat pastoral district, with low hills to the south, on the Warwickshire Avon, close to its junction with the Severn. The Severn is crossed by an iron bridge with a flattened arch of 170 ft. span, erected by Telford in 1824. Of the great Benedictine abbey, one of the richest foundations in England, refounded and enlarged by Sir Robert Fitz-Hamon in the 12th century on the site of an ancient hermitage and Saxon monastery, there only remain the gate and a few other fragments. The abbey church, however, consecrated in 1125, is a magnificent specimen of early Norman. This elaborate cruciform building consists of nave and side aisles, with transepts united by a grand central tower richly arcaded. The choir terminates in an apse and is surrounded by an ambulatory. One of the most remarkable features of the building is the unique western front, the central part of which is occupied by one vast arch extending from the ground to the roof. Originally it was filled in with Norman windows, but a Perpendicular window now occupies the space. The whole building underwent restoration in the Decorated period, and of this style it is one of the finest existing examples. The Norman windows in the nave were replaced, and stone groining was substituted for the carved wooden ceiling, a like transformation taking place in the transepts. The Norman columns in the choir still exist; but above them rises a grand superstructure of Decorated work. The elegant clerestory windows are of the 14th century, with stained glass of the same date. The ambulatory was rebuilt some distance farther out, and from it projected a beautiful series of chapels. The elaborate tombs include those of Sir Robert Fitz-Hamon, the De Spensers, Alan prior of Canterbury, Sir Guy de Brien, and the vault of George duke of Clarence (murdered in the Tower) and his wife Isabella. Edward, prince of Wales, slain after the battle of Tewkesbury (1471) by the Yorkists, is also buried in the church. Of the two organs, one, dating from the early 17th century, is of singularly beautiful tone. In the High Street there are several ancient timbered and gabled houses. Remains of an ancient wall have been discovered adjoining the town. There are a free grammar school (1625) and a number of charities and almshouses. Tewkesbury is chiefly dependent on its agricultural trade. Below the junction of the rivers there is a great lock and weir on the Severn, up to which the stream is sometimes reversed by the tidal bore. The borough is under a mayor, 4 aldermen and 12 councillors. Area, 2532 acres.

Remains of Roman encampments and roads prove that the earliest settlement near Tewkesbury (*Theotesburg*, *Theockesburia*, *Thooksburi*) of which we have evidence was a military encampment against the British. It was the site of a Saxon castle and monastery, and its position near navigable rivers led to the growth of a town, which was a borough with a market in 1087 when it was part of the royal domain. It was subsequently granted to Earl Robert of Gloucester, who granted a charter before 1107, which exempted the borough from certain tolls and from suit at the hundred court. Edward III. confirmed this charter in 1337, and made Tewkesbury free from tolls throughout England. The borough was incorporated by Elizabeth by a charter of 1574, which was confirmed in 1604, 1605, 1609 (when the manor and borough were sold to the corporation) and 1685, while the town was governed under the charter granted by William III. in 1698 until the corporation was remodelled in 1835, the modern government consisting of a mayor, 4 aldermen and 12 councillors. Tewkesbury returned two members from 1609 to 1867, when it lost one member, and in 1885 the representation was merged in that of the county. A fair on July 20 was granted in 1323, and fairs on September 21 and August 24 in 1440, and on April 25 in 1574. For the last May 3 was substituted in 1605, and two more fairs on June 11 and September 29 were granted in 1609. All these grants were confirmed by the charter of 1685. One fair only is now held, on October 10. It is a pleasure fair and a fair for hiring servants, and has lost the commercial importance of the early wool fairs. The long-existing provision trade along the four rivers declined through railway competition. Cloth-making lasted from the 11th century until the beginning of the 18th; gloving in the 17th century was followed by worsted-combing in the 18th. Cotton-thread lace-making, introduced in 1825, collapsed about 1862. Tewkesbury was once celebrated for the manufacture of mustard, which ceased to be important at the end of the 18th century. Stocking-frame knitting was the chief trade in 1830, but has been replaced by the boot and shoe trade. Tewkesbury was strategically important in the Wars of the Roses, and was the site of a battle in 1471, and in the Civil War was four times besieged.

See *Victoria County History, Gloucestershire*; James Bennet, *History of Tewkesbury* (1850); William Wyde, *History of Tewkesbury* (1798).

TEXARKANA, two adjoining cities forming one community, situated on either side of the boundary line between Arkansas and Texas, U.S.A., about 165 m. E. by N. of Dallas, Texas; Texarkana, county-seat of Miller county, Arkansas, pop. (1900) 4914, of whom 120 were foreign-born and 2078 were negroes; (1910) 5655; Texarkana, Bowie county, Texas, pop. (1900) 5256, of whom 192 were foreign-born and 1964 were negroes; (1910) 9790. Texarkana is served by the Kansas City Southern (Port Arthur Route), the Texas & Pacific (of which it is the eastern terminus), the St Louis, Iron Mountain & Southern (Iron Mountain Route, the southern terminus), and the St Louis South-Western (Cotton Belt Route) railways. The public buildings are two city halls, a well-designed Post Office, which stands on the state line and serves both cities, a county court house (on the Arkansas side), and a Federal court building (on the Texas side). The chief trade is in lumber (especially hard woods, such as white oak and ash), cotton, cotton-seed oil and hides. Natural gas is piped here from the Caddo gas-fields, about 48 m. S., in Louisiana. The first permanent settlement here was made in 1874; Texarkana, Texas, was incorporated in 1875, and Texarkana, Arkansas, in 1881.

TEXAS, a south central state of the United States of America, extending from lat. 26° 51′ N. to lat. 36° 39′ N. and from long. 93° 30′ W. to long. 106° 30′ W. A western projection is bounded N. by New Mexico, but the main portion of the state is bounded N. by Oklahoma, from which it is separated in part by the Red river; a northern projection (the Panhandle) is bounded E. by Oklahoma, but the main portion is bounded E. by Arkansas and Louisiana, the Sabine river separating it in part from Louisiana; on the S.E. the state is bounded by the Gulf of Mexico; on the S.W. by Mexico, from which it is separated by the Rio Grande; on the W. by New Mexico. Texas is much the largest state in the Union. Its length and breadth are nearly equal—about 750 m.—and its area is 262,398 sq. m., of which 3498 sq. m. are water surface.

Physical Features.—Texas is crossed by four physiographic provinces. In the S.E. are the West Gulf Plains, a part of the Coastal Plain province. Thence westward to the 100th meridian are the prairies, the south-westward extension of the Prairie Plain province. The Great Plains (really a plateau) comprise the W. half of the state, except a mountainous area in the W. part of the Panhandle, which belongs to the Basin Range province. The surface is principally a series of plains sloping S.E. from the high plateau or from the mountains in the W. to the low shore of the Gulf of Mexico. The mountains of the Basin Range region, known in Texas as the Trans-Pecos Province, rise in Guadalupe Peak near the border of New Mexico, to nearly 9000 ft. (the greatest elevation in the state), and the Great Plains have a maximum elevation in northern Texas exceeding 4000 ft., but from these heights the surface descends to sea level and the mean elevation of the state is about 1700 ft. The Gulf Plains have a coast line of about 400 m., and are bordered along the Gulf of Mexico by a series of long narrow islands and peninsulas, or sandbars, which have been formed by the waves breaking on the shelving shore. Padre, the longest of these islands, extends northward from the mouth of the Rio Grande more than 100 m. Back of the islands are the quiet waters of lagoons, and at the mouths of rivers are several shallow bays indenting the mainland; these bays were formed by only a slight subsidence of the land and the rivers are filling them with deposits of silt. For 20 m. or more inland in the N. and for 50 m. inland in the S. the Gulf Plains are low and flat, seldom rising as much as 100 ft. above the sea, but farther W. the surface is more broken and rises to a maximum elevation of about 700 ft. Along a line drawn approximately S.S.W. from the S.E. corner of Oklahoma, the N.W. part of the Gulf Plains merges with the Prairie Plains. The N.E. portion of the Texas Prairie Plains is only gently rolling, but the S. portion is quite rugged, and the W. half rises in a succession of scarps or steps to an elevation of 2500 ft., to the Great Plains region, which extends westward past the valley of the Pecos river. One of the scarps or steps is the result of a great fault or displacement of the earth's crust, and is known as the Balcones fault scarp; others are due to erosion and weathering of alternate layers of hard and soft rocks lying almost horizontal. South of the parallel of the S. boundary of New Mexico the Great Plains province is known as the Edwards Plateau; between the Edwards Plateau and the valley of the Canadian river, as the Llano Estacado, or Staked Plains; and N. of the Canadian Valley, as the North Plains. The E. and S. parts of the Edwards Plateau and the E. margin of the Llano Estacado have been much dissected by headward erosion of streams, but the central portion of the Edwards Plateau and nearly all of the Llano Estacado have a notably even surface rising slowly to the north-westward. In the S.E. corner of the Trans-Pecos Province is a smaller plain known as the Stockton Plateau, but the remaining portion of this province is traversed from N.E. to S.W. by isolated mountain ranges of the Basin Range or block mountain type.

The N. portion of the Panhandle is drained by the Canadian river eastward into the Arkansas. The S. portion of the Panhandle and a strip along the N. border of the state, E. of the Panhandle, is drained by the Red river south-eastward into the Mississippi. The rest of the state is drained S.E. directly into the Gulf of Mexico. The Rio Grande and its principal tributary, the Pecos, drain narrow basins in the S.W.; these two rivers and the Canadian river rise in the Rocky Mountains in Colorado and New Mexico, but all the other rivers by which the state is drained rise within its borders. The Red, the Brazos, the Colorado, the Guadalupe, and the Nueces rise on the E. or S.E. border of the Great Plains; the Sabine and the Trinity, on the Prairie Plains; and numerous small streams, on the Coastal Plain. In the Great Plains region and in the Trans-Pecos Province the rivers have cut deep canyons, and the character of the longer rivers in their upper courses varies from mere rivulets late in summer to swift and powerful streams during spring freshets. Most of the large Texas rivers have deposited great quantities of silt along their lower courses on the Coastal Plain, where the current is often sluggish and the banks are periodically overflowed. Texas has no large lakes; but freshwater lakes, which are fed either by streams or springs, are common on the Coastal Plain; the best known of them are Grand Lake in Colorado county, Clear Lake in Harris county, and Caddo Lake on the Louisiana border. On the Llano Estacado there are both freshwater and salt lakes, and there are a few salt lakes in the Trans-Pecos Province and near the mouth of the Rio Grande on the Coastal Plain.

The Texas Cretaceous is notably rich in the fossil remains of an invertebrate fauna and in the vicinity of Waco Cretaceous fossils of vertebrates have been obtained. Fossils of both vertebrates and invertebrates are also common in the Permian and Jurassic formations.

Fauna.—The varied fauna and flora of Texas may be classified in the following life-zones: the Canadian zone, on the highest parts of the Davis Mountains; the Transition zone, including high parts of the Davis, Chisos and Guadalupe mountains; the Upper Austral zone, Upper Sonoran division, in the Panhandle, E. of the Pecos Valley, and in the Staked Plain and Edwards Plateau; and the widely extending Lower Austral zone, covering most of the state and subdivided into the Lower Sonoran or arid western part, the Austroriparian, or humid eastern, and the narrow Gulf Strip, which is semi-tropical. Originally great herds of bison roamed over the Texas plains, and deer, bears and wolves were numerous, especially in the forests. Only a few of the larger wild animals remain, but the Texas fauna is still varied, for it includes not only many species common to northern and eastern United States but also several Mexican species. The few remaining bison are on a ranch near Goodnight, in Armstrong county, where they have been crossed with polled Angus cattle. White-tailed, Sonora, and grey mule-deer (*Odocoileus*) are found in the south-western counties; and there are a few antelope (*Antilocapra Americana*) in the west. Louisiana bears (*Ursus luteolus*) still inhabit the inaccessible canebrakes near the coast, and occasionally one is found farther west; and in the western mountains black (and cinnamon) bears, including the New Mexico black bear (*Ursus Americanus amblyceps*) still are found. Coyotes or prairie wolves (of which there is a local sub-species, *Canis nebracensis texensis*), grey wolves, prairie dogs (gophers), and jack rabbits are common on the plains; less common are the grey wolf or lobo (*Canis griseus*) and the timber wolf; and there are several species of foxes, including the swift. Cottontail rabbits, raccoons (including the Mexican variety), and squirrels are common in the forests. A few otters, beavers and minks are still found in eastern Texas. Opossums and skunks (several varieties of the *Mephitis* and several of the *Spilogale*, including *S. interrupta*, the prairie spotted skunk or "hydrophobia cat") are found in nearly all parts of the state. The peccary (*Tayassu angulatum*), the armadillo (*Tatu novemcinctum*), the civet-cat (*Bassariscus astutus flavus*), the Mexican bighorn (*Ovis mexicanus*) and the jaguar are Mexican species found in southern or south-western Texas. The Mexican cougar (*Felis hippolestes aztecus*) is found in the west. Other felines are the ocelot (*F. pardalis limitis*) and red and grey cats (*F. cacomitli*) in the south, the Texan lynx (*Lynx rufus texensis*) in the south-east, and the plateau wild cat (*L. baileyi*) in the west. There are several varieties of grasshopper mice (*Orychomys*), white-footed mice (*Peromyscus*), harvest mice (*Reithrodontomys*), rice-rats (*Oryzomys*), wood-rats (*Neotoma*), voles (*Microtus*), &c. Bats inhabit caves in Burnet, Williamson, Lampasas, Gillespie and other counties. The mocking-bird is the principal song bird and it and the lark-sparrow are common throughout the state. The snowy heron is a rare plume bird seen occasionally along the coast. The scissor-tailed flycatcher, or Texas bird of paradise, is common on the prairies and in the lightly wooded districts. The Texas screech-owl, the Texas woodpecker, and the road runner, or ground cuckoo, are found mostly in southern and south-western Texas. Among birds common in Texas as well as in the other Southern States are the cardinal, golden-fronted woodpecker, Mississippi kite, mourning-dove, and turkey-buzzard. In a narrow strip along the Gulf there are some Mexican or tropical birds, notably the caracara and two varieties of grackle (*Megaquiscalus*). The Texas Bob White or Texas quail is found principally in Texas and a few neighbouring states. The Texas game birds consist chiefly of plover, snipe, teal, mallard and wild geese. Texas has also the American coot or mud-hen and the pelican. Of reptiles there are the alligator, and several species each of turtles, lizards and snakes. Alligators are found in the low coast region and are especially numerous in the Nueces river. The painted box tortoise is common in the central part of the state; the snapping-turtle and the soft-shell turtle in most of the rivers and creeks; the Louisiana mud-turtle, in the coast marshes. The horned lizard, or horned toad (*Phrynosoma cornutum; P. hernandesi; P. modestum*), is the most common of Texas lizards, except in the western counties where the Texas rock lizards (*Sceloporus torquatus*; *S. clarkii*; *S. spinosus*; *S. consobrinus*; *S. dispar*) are numerous. The tree swift, or scaly lizard, is also an inhabitant of western and south-western Texas. The green lizard, the fence lizard and whip-tailed lizard (*Cnemidophorus gularis*; *C. sexlineatus*; *C. tesselatus*, &c.) are quite widely distributed. The Gila Monster (*Heloderma suspectum*), a poisonous lizard, whose bite is injurious but rarely, if ever, fatal to man, also occurs in the desert regions. The blow snake, or spreading adder (*Heterodon platyrrhinus*), black snake (*Bascanion constrictor*), coach whip (*Bascanion flagellum*), and prairie bull snake (*Pituophis*) are common; the diamond water snake (*Natrix fasciata*) is found along creeks; the king snake (*Lampropeltis getula*), in central and southern Texas; and the pilot snake (*Callopeltis obsoletus*), mostly in the woods of McLennan county. Among venomous snakes the harlequin, or coral snake (*Elaps fulvius*) is common along the coast; the copperhead (*Agkistrodon contortrix*) along the wooded banks of creeks and rivers; the cottonmouth (*Agkistrodon piscivorus*), in all parts of the state except the more arid districts; the "sidewiper," or massasauga (*Sistrurus catenatus consors*, sometimes called *Crotalophorus tergeminus*) and the ground rattlesnake (*Sistrurus miliarius*), in all sections. The green rattlesnake (*Crotalus molossus*) inhabits the valley of the Rio Grande; the plains rattlesnake (*Crotalus confluentus*), the north-western counties; the diamond rattlesnake (*C. adamanteus*), the wooded river bottoms; the Texas rattlesnake, western Texas and the southern coast counties; the banded rattlesnake, a few widely separated woodland districts. There are several varieties of the skink (*Eumeces*). Freshwater fish, consisting mostly of catfish, buffalo fish, bass, sunfish and drum, are common in the lower courses of the rivers. Oysters, clams, and shrimp abound along the coast, and there are more than 500 species of mollusks in the state. The boll-weevil, preying on the cotton, is the most noxious of the insects.

Flora.—The arboreal flora of Louisiana and Arkansas extends into north-eastern Texas, conformable with the Coastal Plain, where, immediately south of the Colorado river, the great pine belt of the Atlantic and Gulf coasts terminates. The flora of the Great Plains region, consisting principally of nutritious grasses, enters the north-western portion of the state and extends south to the Edwards Plateau and east into the Prairie Plains region. The peculiar plants of the Rocky Mountain plateaus penetrate into the Trans-Pecos region, which the north Mexican flora, including the *Agave lecheguilla*, a valuable commercial fibre, is found along the Rio Grande. The central region is a transition ground where these floras find representation generally in deteriorated and dwarfed species. The long-leaf pine is the dominant forest tree on the uplands of the Coastal Plain, north of the Colorado river, for 100 m. or more from the coast; farther inland and especially in the north-eastern corner of the state, it is succeeded by the short-leaf pine. Between the rising swells of long-leaf pine lands are impenetrable thickets of hawthorn, holly, privet, plane trees and magnolias. Loblolly pine, cypress, oaks, hickory, ash, pecan, maple, beech and a few other deciduous trees are interspersed among both the long-leaf and the short-leaf pines, and the proportion of deciduous trees increases to the westward. In the broad river valleys of the eastern part of the Prairie Plains region are forests and isolated groves consisting principally of pecan, cypress, cottonwood and several species of oak. Farther west two narrow belts of timber, consisting mostly of stunted post oak and black jack, and known as the Eastern and Western Cross Timbers, cross the prairies southward from the Red river, and a low growth of mesquite, other shrubs and vines are common in the eastern half of the Prairie Plains. The western half of these plains has only a few trees along the watercourses and some scraggy bushes of oak, juniper and cedar in the more hilly sections. In the canyons of the Edwards Plateau grow the pecan, live oak, sycamore, elm, walnut and cypress; on the hilly dissected borders of the same plateau are cedars, dwarf and scrubby oak, and higher up are occasional patches of stunted oak, called "shinneries." The upper slopes of some of the mountains in the Trans-Pecos region are clothed with forests of large pines, cedars and other trees. Smaller trees and shrubs grow farther down the same mountain slopes, but other mountains and the valleys are wholly destitute of trees. The entire valley of the Rio Grande, from El Paso to Brownsville, grows many species of cactus, and other prickly coriaceous shrubs. The low country along the coast is covered chiefly with grasses and rushes, but scattered over it are clumps of live oak, called "mottes." Grasses representing several species also cover most of the Great Plains, the uplands in the southern portion of the Coastal Plain, and the treeless portions of the Prairie Plains and the Trans-Pecos region.

Climate.—In the region of Galveston, along the northern section of the coast, where southerly or south-easterly winds from the Gulf prevail throughout the year, the climate is warm, moist and equable, but the moisture decreases westward and south-westward, and the equability, partly because of northerly winds during the winter months, decreases in all directions inland. The mean annual temperature decreases to the north-westward with an increase of both altitude and latitude, and ranges from 73° F. in the lower Rio Grande Valley to 55° F. in the northern portion of the Panhandle. The range between the mean of the maxima of the summer months (June, July and August) and the mean of the minima of the winter months (December, January and February) is only from 88° to 50° at Galveston, but at Mount Blanco, Crosby county, on the eastern border of the Llano Estacado, it is from 90° to 26°. During a period of twenty-six years (from January 1882 to December 1908) the greatest extremes that were recorded in the state by the United States Weather Bureau were 113° at El Paso in June 1883 and −16° at Amarillo, Potter county, in the Panhandle, in February 1899; within the same period the extremes at Galveston ranged only from 98° to 8°. Along the coast the average number of days during a year in which the temperature falls below freezing-point is only 3 or 4, but in the Panhandle this average is 111. January is the coldest month in nearly all parts of the state and July is the warmest. The mean temperature for January decreases from 59° at Brownsville, at the southern extremity of the state, to 36° at Amarillo in the Panhandle. The mean temperature for July is 85° both at Beeville, Bee county, in the southern coast region, and at Waco, much farther north but also farther inland; at Amarillo it falls to 76°. The average annual rainfall decreases quite regularly westward and south-westward from 47·6 in. at Galveston to 9·3 in. at El Paso. Along the coast the autumn months are the wettest and the spring months are the driest; for example, at Galveston the rainfall amounts to 5·7 in. in September and only 2·9 in. in April. In the middle, eastern and north-eastern parts of Texas the spring months are the wettest and the winter months are the driest; for example, at Waco the rainfall amounts to 4·5 in. in May and only 1·9 in. in December. In the western and south-western parts the summer months are the wettest and the spring months are the driest; thus, at El Paso the rainfall amounts to 2·2 in. in July and only 0·2 in. in April. The average annual snowfall for the state is about 5 in., ranging from 19 in. in the northern portion of the Panhandle to scarcely any along the coast and in the lower Rio Grande Valley. The prevailing winds are southerly or south-easterly throughout most of the state in spring and summer. Along the coast they continue in the same direction throughout the year, but inland they usually shift to the north or north-west either in autumn or winter.

Soils.—The Coastal Plain has for the most part a light sandy soil, but there is a fertile alluvium in the river bottoms and good clay soils on some of the uplands. The eastern part of the Prairie Plains is a belt known as the Black Prairie, and it has a rich black soil derived from Upper Cretaceous limestone; immediately west of this is another belt with a thinner soil derived from Lower Cretaceous rocks; a southern part of the same plains has a soil derived from granite; in a large area in the north-west the plains have a reddish clay soil derived from Permian rocks and a variety of soils—good black soils and inferior sandy and clay soils—derived from Carboniferous rocks. A very thin soil covers the Edwards Plateau, but on the Llano Estacado are brownish and reddish loams derived from the sediments of a Neocene lake.

Agriculture.—The total farm acreage was 125,807,017 acres in 1900, the total number of farms [1] being 351,085, their average acreage 358·3 acres, 84·9 per cent. being operated by white farmers. There were 11,220 farms of 1000 acres and more; 10,183 between 500 and 1000 acres; 115,393 between 100 and 500 acres; and 88,537 between 50 and 100 acres.

The production of Indian corn was 122,250,000 bu. in 1909 (valued at $92,910,000); the wheat crop, 5,050,000 bu. (valued at $5,959,000); the oat crop, 11,500,000 bu. (valued at $7,130,000); the rice crop, 9,894,000 bu. (valued at $7,717,000); the acreage under hay was 618,000, the crop being 587,000 tons and its value $6,985,000. Texas ranked first in 1899 among the states in the production and value of cotton, the acreage of which increased from 2,178,435 acres in 1879 to 6,960,367 acres in 1899, and the number of commercial bales from 805,284 in 1879 to 2,506,212 in 1899, when the total crop was valued at $96,729,304. The estimates for 1909 were 9,334,000 acres and 2,570,000 bales.

In the value of live stock on farms and ranges, Texas ranked seventh among the states in 1880 and second in 1900, with a value of $240,576,955. The value of all domestic animals on farms and ranges in 1900 was $236,227,934, Texas ranking second in this respect among the states. The censuses from 1860 to 1900 showed a far greater number of neat cattle on farms and ranges in Texas than in any other state or Territory; in 1900 the number was 7,279,935 (excluding spring calves); and in 1910 there were 8,308,000 neat cattle including 1,137,000 milch cows. In the number of horses the state ranked third in 1900, with 1,174,003 head—excluding colts—and in 1910 with 1,369,000 head. In the number of mules the state ranked first by a wide margin in 1900, with 474,737 head, and in 1910 with 702,000 head. In the number of swine the state ranked eighth in 1900 with 2,665,614 head, and third in 1910 with 3,205,000 head. In the number of sheep the state rose from fourth rank in 1880 to first in 1890, but dropped to tenth rank in 1900, when there were 1,439,940 head; in 1910

[1] Not including farms of less than three acres and of small productive capacity.

there were 1,909,000 sheep in the state. The wool product of the state in 1900 was 9,638,002 lb, and in 1910 was 8,943,750 lb washed and unwashed and 3,040,875 lb scoured. In the number of chickens (13,562,302 in 1900) the state ranked fifth, and in the number of ducks, geese and turkeys (1,299,044 in 1900), ranked first.

The cereals grow generally throughout the state, excepting in the arid western lands. The crop of Indian corn is especially large in a belt of counties beginning near the north-eastern corner of the state and extending in a south-westerly direction. Most of the rice is raised along the seaboard, in the south-eastern corner of the state. The largest crops of cotton are grown in the cereal-growing counties.

Forests and Timber.—About 64,000 sq. m., or 24 per cent. of the area of Texas, is estimated to be wooded. The area of yellow pine forests (the stand is estimated at 67,568·5 million ft.), and the lesser one of hardwood, together with considerable softwood, represent lumber-producing possibilities of much economic importance. The pine and hardwood areas occur chiefly in the north-eastern part of the state, and are bordered on the west by scattering growths of hardwood, extending as far westward as Austin. Sparse scrub timber, of little value except for posts, poles and rough beams and for fuel, occupies the region westward to approximately the longitude of the Pease river. Outside of these general areas, forest products are of relatively little value, the exceptions being the dense growths, in certain restricted areas, of live-oak, which is in demand for ship timbers; and scattering patches of hickory, which is requisite for certain manufactures. The pine and hardwood forests are of great economic value because of the density of their growth, and there are at hand the means of profitable development of this industry in the numerous watercourses which make logging cheap and expeditious. The maple, walnut, oak, ash, beech, elm, gum, sycamore, hickory and poplar, found on the southern slope of the Osage highlands, on the uplands about the source of the highlands and in the central portions of the Red river valley, are valuable for cabinet woods. The cut, consisting almost entirely of yellow pine, was valued in 1900 at $16,296,473.

Fisheries.—The value of the fisheries product of Texas increased from $286,610 (7,174,550 lb) in 1897 to $353,814 (8,044,404 lb) in 1902; and the amount of capital invested in the industry from $237,496 in 1897 to $373,724 in 1902, but the number of wage-earners employed decreased slightly—from 1199 in 1897 to 1144 in 1902. The values of the principal catches in 1902 were: red snapper, $103,398; oysters, $100,359; squeteague, $49,577, and channel bass, $39,525.[1]

Minerals.—The total value of the mineral products of Texas in 1890 was $1,986,679; in 1902, $6,981,532; in 1907, $19,806,458, and in 1908, $15,212,929—the valuations for the two years last named being those of the United States Geological Survey. By far the largest item in these totals after 1902 represented the value of petroleum. Little attention was paid to this resource until 1883; in 1890 the product was valued at only $227; and five years later it had increased to only $250. A good quality of oil—better in fact than the Ohio product, but not as good as that of Pennsylvania—was accidentally found at Corsicana, Navarro county, about 1894, and in 1898 it was discovered at a depth of 1040 ft. In 1901 an extraordinary "gusher" well was drilled near Beaumont, Jefferson county; in the nine days before this well was capped, it threw a stream of oil 160 ft. high, and poured out about 500,000 barrels. The development of the Hardin county field also began in 1902. As the result of these developments, the value of the oil product increased from $277,135 (546,070 bbls.) in 1898, to $871,996 (836,039 bbls.) in 1900; to $4,174,731 (18,083,658 bbls.) in 1902; and to $10,410,865 (12,322,696 bbls.) in 1907; it decreased to $6,700,708 (11,206,464 bbls.) in 1908. The value of the bituminous coal output was $465,900 (184,440 short tons) in 1890; $1,581,914 (968,373 short tons) in 1900; $2,778,811 (1,648,069 short tons) in 1907; and $3,419,481 (1,805,377 short tons) in 1908. The value of the product of limestones and dolomites in 1900 was $124,728; in 1902, $228,662; of sandstones and quartzites in 1900, $37,038; in 1902, $165,565; while the value of all stone produced in 1907 was $497,962, and in 1908, $659,574. Natural gas was discovered in Washington county in 1879, but was not commercially used in that vicinity until 1888. In 1902 gas was discovered in Jefferson county. Other minerals found in small quantities are copper, lead, zinc, iron ores, manganese ores and tin.

Manufactures.—The value of the manufactured products of Texas in 1905 was $150,528,389, the capital invested in manufacturing being $115,664,871, and the number of factories, 3158.

In the value ($14,005,324 in 1900[2] and $18,698,815 in 1905) of its cotton-seed oil and cake product Texas surpassed all other states. Flour and grist mill products advanced in value from $11,948,556 in 1900 to $22,083,136 in 1905. The values of other products in 1905 were as follows: slaughtering and meat packing (wholesale), $15,620,931; lumber and timber products (which employed the largest average number of wage-earners—13,332, or 27·2 per cent.), $16,278,240; cars and general shop construction and repairs by steam railway companies, $10,472,742; printing and publishing, $7,782,247; foundry and machine shop products, 1905, $4,952,827; malt liquors, $4,153,938; saddlery and harness, 1905, $3,251,525. The highest average quantity of rough milled rice per establishment in the United States in 1905 was for Texas, where seventeen establishments produced an average of 18,598,259 lb, valued, together with that of other rice products, at $4,638,867.

Transportation.—Until the middle of the 19th century transportation facilities remained practically undeveloped in Texas. In 1860 the steam railway mileage was 307 m.; in 1870, 711 m.; in 1880, 3244 m.; in 1890, 8709 m.; in 1905, 11,949 m.; in 1907, 12,877 m.; and in 1908, 13,066 m. Most of this mileage is in the eastern part of the state, the western and southern portions having slight railway facilities. The principal railway systems are the Southern Pacific, the Santa Fé, the Texas & Pacific and the Colorado & Southern. The inland waterways include the 25 ft. ship canal from the Gulf to Port Arthur (the Port Arthur Canal), opened in 1899, and transferred to the United States government in 1906; the Galveston and Brazos River canal, 29·5 m. long and of a ruling depth of 3 ft., also acquired by the government in 1902, and a privately owned canal, 9 m. long and from 6·5 ft. to 10 ft. deep, extending from Corpus Christi to Aransas Bay. Other important waterways which have been authorized by the United States government and on which work was proceeding in 1910 are canals from the Rio Grande river to the Mississippi river at Donaldsonville, Louisiana; and "a navigable channel depth of 5 ft. in a canal along the coast of Texas, underlying the lagoons lying between the islands and the mainland" to develop light navigation to points not reached by the railways. Another important undertaking is the deepening of the Trinity river to Dallas, a distance of 511 m., thereby affording a navigable waterway almost to the northern boundary of the state. Congressional appropriations for the survey, improvement and maintenance of waterways began in 1852; amounted to $15,055,688 between 1891 and 1896 inclusive, and $1,613,829 between 1897 and 1907; the total appropriated being $23,249,419. The ports of entry of Texas are Galveston, Corpus Christi, Eagle Pass, El Paso and Brownsville.

Population.—The population in 1880 was 1,591,749; in 1890, 2,235,523; in 1900, 3,048,710; and in 1910, 3,896,542.[3] Of the population in 1900, 94·1 per cent. was native born, 79·6 per cent. was white and 20·4 per cent. (or 620,722) was negro, or of negro descent. There were in 1900, 2,249,088 native whites, 179,357 persons of foreign birth, 836 Chinese, 470 Indians and 13 Japanese. Of the inhabitants born in the United States 130,389 were natives of Tennessee, 129,945 of Alabama, 90,584 of Mississippi, 77,950 of Georgia and 75,633 of Arkansas; and of the foreign-born 71,062 were Mexicans, 48,295 Germans, 9204 Bohemians, 8213 English, 6870 Austrians and 6173 natives of Ireland. Of the total population 471,573 were of foreign parentage—*i.e.* either one or both parents were foreign-born, and of those both of whose parents were foreign-born 70,736 were of German, 10,967 of Bohemian, 7759 of Irish and 6526 of Austrian parentage. In 1906 1,226,906 inhabitants of the state were members of religious societies. Of these 401,720 were Baptists; 317,495 Methodists; 308,356 Roman Catholics; 62,090 Presbyterians; 39,550 Disciples of Christ; 34,006 members of the Churches of Christ; 27,437 Lutherans; 14,246 Protestant Episcopalians; 7745 members of the German Evangelical Synod of North America, and 1856 Congregationalists. The principal cities are San Antonio, Houston, Dallas, Galveston, Fort Worth, Austin, the capital, Waco, El Paso, Laredo, Denison and Sherman.

Administration.—Texas as a part of Mexico was governed under the constitution (1827) of the "Free State of Coahuila and Texas"; a separate constitution adopted in 1835 was never recognized by the Mexican government and never went into effect. The Texan Declaration of Independence, adopted in November 1835, was accompanied by a provisional constitution; and with the Declaration of Independence of March 1836 there were adopted an executive ordinance and a constitution. As a state of the United States Texas adopted a constitution in 1845, another in 1866, and a third in 1868, and is now

Emery Walker sc.

governed under the constitution of 1876, with amendments of 1879, 1883, 1890, 1891, 1897, 1904 and 1906. All male citizens over twenty-one years of age and resident in the state for one year and in the county or election precinct for six months immediately preceding election (except paupers, idiots, lunatics, felons, United States soldiers, marines and seamen, and persons who have taken part, either as principal or second, in fighting a duel or in sending a challenge) have the right of suffrage. The constitution originally forbade the registration of voters, but an amendment of 1891 permits it in cities having a population of ten thousand or more, and the Australian ballot system was adopted in such cities by an act of the twenty-second legislature in 1892. An amendment to the constitution may be proposed by a two-thirds vote of all members elected to each house of the legislature, and is adopted if it is approved by a majority of the popular vote on the amendment.

The executive department consists of a governor, lieutenant-governor, secretary of state, comptroller of public accounts, treasurer, commissioner of the general land office, and attorney-general. Contrary to the usual custom in other states, the secretary of state is appointed by the governor. The other officials are elected by popular vote for two years' terms. The governor and lieutenant-governor must be, at the time of election, at least thirty years of age, citizens of the United States, and residents of the state for the preceding five years. The governor receives an annual salary of $4000 and the use of the governor's mansion. His functions are rather more extensive than those of the average American executive. In addition to the usual privilege of granting pardons and reprieves, he controls considerable patronage, and possesses a power of veto which extends to separate items in appropriation bills. A two-thirds majority in each house is necessary to override a veto.

The legislature of the state is composed of a Senate and a House of Representatives. The Senate consists of thirty-one members, chosen by popular vote for four years, one-half retiring every two years. Representatives are elected biennially. Their number, originally ninety-three, is determined by apportionment bills passed after the publication of each Federal census, but under the constitution it can never exceed one hundred and fifty. Senators and representatives must be at least twenty-six years old, citizens of the United States, qualified electors of the state, and residents of the state for two years, and of the district for one year, preceding the election. The unusual provision that two-thirds of each house shall constitute a quorum would probably prove inconvenient, if the political parties were approximately equal in strength. Bills for raising revenue may originate only in the House of Representatives, but may be amended or rejected by the Senate. Meetings of the legislature are biennial, although special sessions may be called by the governor.

The judicial system, revised by a constitutional amendment of 1891, consists of a supreme court of three members, elected for a term of six years, with civil jurisdiction only, largely appellate; a court of criminal appeals, of three members, elected for six years, with appellate jurisdiction in criminal cases; courts of civil appeals (number determined by the legislature) of three members each, elected for six years; district courts, each with one judge, elected for four years, with original jurisdiction in the more important civil and criminal (felony) cases and a limited appellate jurisdiction; county and justice of the peace courts with original jurisdiction in misdemeanours and petty civil cases. The commissioners' court of five members, including the presiding judge, attends to county business matters, the county being the unit of local government.

Miscellaneous Laws.—The long domination of Spain and Mexico exercised an influence on the institutions of the state, but it can easily be exaggerated. It must be remembered that during the colonial period the Spanish and Mexican population was never very large, that the first permanent Anglo-American settlement was not established until 1821, that there was ill-feeling between the two peoples almost from the very beginning, and that in fifteen years the Americans carried through a successful rebellion. The framework of the governments established in 1836–37 and 1845 was not essentially different from those with which the framers were familiar in the United States. But while this was true of the outward structure it was impossible to disregard entirely private rights based upon Spanish and Mexican legislation. In other words, the system of jurisprudence is the most striking example of Spanish influence. There was the same conflict between the English Common Law and the Roman Civil Law which had taken place in Louisiana a few years before (see LOUISIANA); but the result was different. Owing to the peaceful character of its acquisition and the relative strength of the Romance (French) element, Louisiana continued the use of the Civil Law. The Texas invaders, on the other hand, adopted the Common Law, but with the addition of many Civil Law principles. For example, the state has never made any distinction between law and equity, and it has always followed the Civil Law procedure by petition and answer.[1] The independent existence of Texas as a republic (1836–45) was also not without influence. By strengthening the feeling of local pride it added force to the states' rights sentiment, and it enabled the state on coming into the Union to retain possession of all its public lands. This vast domain has been utilized to provide homes for settlers, to encourage education, to subsidize railways, and to build the state capitol. There is a general land office at Austin under the charge of a commissioner. Among other features of interest the constitution forbids the suspension of the writ of *habeas corpus*, makes duelling a disqualification for holding office or exercising the right to vote, and authorizes the exclusion of atheists from office. There is also a clause which exempts from seizure for debt the homestead, not more than two hundred acres of land in the country, or a house of any value in a city or town on a lot or lots not exceeding five thousand dollars in value at the time of its designation as the homestead. The object is the protection of widows and orphans, but the right has been very much abused, and its abuse is in part responsible for the high rate of interest which prevails. State-wide prohibition of the sale of intoxicating liquors was voted down in 1887 and a local option law went into effect; in 1907, when there was no licence in 145 (out of 243) counties and licence only in parts of 51 other counties, a law was passed giving local option to parts of cities and towns. In 1908–09 there was an unsuccessful attempt to pass in the legislature a constitutional amendment providing for state-wide prohibition; the amendment was favoured by the Democratic state platform, but the hostility of the legislature to Governor Campbell, who favoured the amendment, secured its defeat.

Both husband and wife retain their separate title to the property which each owned before marriage and to that acquired after marriage by gift, devise or descent, and to the increase of all lands thus acquired, but the husband has the sole management both of his own and of his wife's separate property. However, should the husband neglect to sue for the recovery of any separate property of his wife she may, with the permission of the court, sue for it in her own name; or should the husband refuse to support his wife and educate her children as her fortune would warrant, the county court may in answer to her complaint require a fixed portion of the proceeds from her property to be paid to her. All property which either husband or wife acquires during the marriage, other than by gift, devise or descent, is their common property, and during coverture may be disposed of by the husband only; on the death of the husband the widow has one-half of the property, which they held in common. The causes for a divorce are cruelty, adultery, desertion for three years, or conviction after marriage of a felony and imprisonment in the state prison without being pardoned within one year after conviction; the plaintiff must reside in the county six months before beginning suit.

Education.—Educational matters are supervised by a state board, composed of the governor, comptroller and secretary of state, by a superintendent of public instruction, who is *ex officio* secretary of the board, by county superintendents (in counties having a school population of 3000 or more), by superintendents and boards of trustees in corporate towns and cities, and by school commissioners in the rural districts. The permanent public school fund is the largest of any state in the Union; in 1908 it included $38,406,222 in land notes, $15,136,808 in bonds, $7,915,257 (estimated) in leased lands, and $67,956 in cash awaiting investment. The invested fund is largely in Federal, state and county bonds. The revenue for schools in 1907–08 was $8,020,229, of which $2,761,651 was from the state tax, $2,080,159 from the local tax, $1,640,969 from the one dollar poll tax on males between the ages of twenty-one and sixty, $481,899 from a state occupation tax, $429,365 from county funds, and $105,806 from tuition fees. The state apportionment to the districts was $5 per capita of school population in 1906–07, and was $6 in 1907–08. In the latter year the total enrolment in public schools was 777,545, of whom 145,748 were negroes. Separate schools are maintained for white and negro children and impartial provision is made for both races. In 1839 the Congress of the Republic set apart fifty square leagues (221,420 acres) of land for the establishment of two universities. The state legislature approved this grant in 1858, added to the endowment one section (640 acres) out of every ten appropriated to encourage the building of railways, and provided that there should be one university instead of two. The Civil War and Reconstruction delayed the execution of the plan, and the university of Texas was not opened until September 1883. The main university is at Austin, and the medical department (established 1891) at Galveston. The state also supports, wholly or in part: the Agricultural and Mechanical College at College Station (opened in 1876; a land grant college under the Morrill Act of 1862), near Bryan, which has a course in textile engineering besides the courses usually given in state agricultural and mechanical

[1] For a full discussion of this question see E. W. Townes, *Quarterly of the Texas State Historical Association*, ii. 29–53, 134–151 (July and October 1898).

colleges; the Sam Houston Normal Institute (1879) at Huntsville, the North Texas State Normal (1901) at Denton, the South-west Texas Normal (1903) at San Marcos, the School of Industrial Arts for girls at Denton, and the Prairie View Industrial and Normal School (1876) for negroes near Hempstead. The system is not unified or organized: the university's department of education, the school for girls at Denton and the negro normal school all issue teachers' certificates, but are not under the control of the State Department of Education or the State Board of Education. The state library and museum are a part of the Department of Banking, Statistics, History and Insurance. Denominational schools are: Baylor University (Baptist; 1845), at Waco, with a medical department at Dallas; the East Texas Normal and Industrial Academy (Baptist; 1905), at Tyler; Trinity University (Cumberland Presbyterian; 1869), at Waxahachie; Austin College (Presbyterian; 1850), at Sherman; South-western University (Methodist Episcopal; 1873), at Georgetown, with a medical department at Dallas; the Polytechnic College (Methodist Episcopal, South; 1891), at Fort Worth; Texas Holiness College (Holiness; 1899), at Peniel, near Greenville; Texas Christian University (Christian; 1873 until 1895 at Thorp's Spring; until 1902 Add-Ran College), at Waco; St Edward's College (Roman Catholic, under the Congregation of the Holy Cross; 1885), at Austin; St Mary's University (1854; since 1884 under the Society of Jesus), at Galveston; St Basil's College (under the Basilian Fathers; 1899), at Waco; for girls, Baylor Female College (Baptist; 1845), at Belton; San Antonio Female College (Methodist Episcopal, South; 1894), at San Antonio; North Texas Female College (Methodist Episcopal, South; 1877), at Sherman; and the Academy of Our Lady of the Lake, under the Sisters of Divine Providence, at San Antonio; and for negroes Paul Quinn College (African Methodist Episcopal; 1881), at Waco; Tillotson College (Congregational; 1881), at Austin; Samuel Huston College (Methodist Episcopal; 1900), at Austin; Bishop College (Baptist; 1881), at Marshall; Wiley University (Methodist Episcopal; 1873), at Marshall; and Texas College (Coloured Methodist Episcopal; 1895), at Tyler.

Charitable and Penal Institutions.—Texas has done more than any other Southern state for the humane and scientific treatment of its dependent and defective classes. There are insane asylums at Austin (the State Lunatic Asylum), San Antonio (the South-western Insane Asylum), and Terrell (North Texas Hospital for the Insane); the Texas School for the Deaf (1857), an institution for deaf, dumb and blind coloured youths (1889), a School for the Blind (1856), and a home for dependent Confederate soldiers, at Austin, a state orphan home (1889) at Corsicana, an epileptic colony at Abilene, and a state reformatory (1889) for boys under seventeen years at Gatesville. A statute of 1899, authorized by a constitutional amendment of 1897, instituted a system of pensions for Confederate veterans. For this purpose $200,000 was appropriated during the fiscal year 1902–1903. The maximum permitted by the constitution is $250,000 per annum. The penitentiaries are at Huntsville and Rusk, and there is a reform school for juvenile offenders at Gainesville. The convict lease system in its most objectionable form was abolished in 1883, and convicts are now employed on state account or by private contract. There are several state farms in successful operation. Each of these institutions, penal and charitable, has its own superintendent and board of managers, appointed by the governor.

Finance.—The heavy debt incurred in the struggle with Mexico was paid out of the $10,000,000 received from the United States government under the Compromise of 1850. New loans were made during the Civil War, but they were repudiated by the constitution of 1866, and were made void by the Fourteenth Amendment to the Federal constitution. The extravagance of the Reconstruction governments resulted in the accumulation by 1876 of a debt of $4,792,394. The constitution of 1876 forbids the borrowing of money except to supply casual deficiencies of revenue (amount limited to $200,000 at a time), repel invasion, suppress insurrection, defend the state in war, or pay existing debts. The nominal amount of the public debt on the 1st of September 1908 was $3,989,400, but the figures are misleading, because, with the exception of $22,000 (held partly by counties), all of these obligations were in the permanent school fund or in funds for the University, the Agricultural and Mechanical College, and the various charitable institutions. Owing to a clause in the constitution forbidding the issue of bank charters, the financial business of the state was controlled by national and private banks until 1904, when the constitution was amended and provision was made for the incorporation of state banks under a system of state supervision, regulation and control, deposits being guaranteed as in the Oklahoma banking system.

History.—The history of Texas may be regarded as a step in the great struggle between England, France and Spain for the possession of America. The earliest explorations were made by the Spaniards, Cabeza de Vaca, 1528–36, and Francisco Vasquez de Coronado, 1540–42, but the first colony was that planted on Matagorda Bay in 1685 by the French under the Sieur de la Salle. This was, however, soon abandoned, and the field left to the Spanish. Beginning in 1690 they established several ecclesiastical, military and civil settlements known respectively as missions (Franciscan), presidios, and pueblos. In or near the city of San Antonio are the ruins of five missions built of stone; and missions were more numerous in east Texas, but they were built of wood and nothing remains to mark their location. In 1727 the territory, with vaguely defined limits, was formed into a province and named Tejas, or Texas, after the tribe or the confederacy of Tejas Indians. For more than a century the conditions were favourable for colonization. The French in Louisiana proved to be peaceable neighbours, and that province, both under French (to 1763) and under Spanish rule (1763–1803) served as a protection against the English. Spain failed to take advantage of the opportunity, however, and it was lost when the United States purchased Louisiana in 1803. Three abortive Anglo-American invasions during the first few years of the century indicated the future trend of events. The first, under Philip Nolan, in 1799–1801, was poorly supported, and was crushed without difficulty; the second, under Bernardo Gutierrez and Augustus Magee, 1812–13, captured San Antonio and defeated several Mexican armies, but was finally overpowered; the third, under James Long, an ex-officer of the United States army, 1819–21, was less formidable. The year 1821 marks a significant turning-point in the history. By the Florida treaty, finally ratified at that time, the claims of the United States to Texas, based on the Louisiana purchase, were given up, and the eastern and northern boundaries of the province were determined. They were to be, in general terms, the Sabine river, the 94th meridian (approximately), the Red river, the 100th meridian, the Arkansas river, and the 42nd parallel. So far as Spain was concerned this was only a form, inasmuch as Mexico, of which Texas formed a part, was just completing its long struggle for independence (1810–21). In that year also (December 1821) Stephen F. Austin established the first permanent Anglo-American settlement at San Felipe de Austin on the Brazos river. This was followed by an extensive immigration from the United States during the period of Mexican rule (1821–36). It is estimated that the population, exclusive of Indians, increased from four thousand in 1821 to ten thousand in 1827, and nearly twenty thousand in 1830. Most of the settlers came from the southern section of the Union and of course brought their slaves with them, but there is no evidence to show that their object was the territorial extension of slavery, or that the revolt against Mexico was the result of dissatisfaction with that country's anti-slavery policy. Texas was joined to Coahuila in 1827 to form a state of the Mexican federation. Although the attempt to force the Roman Catholic religion upon the people, the federal decree of 1830 forbidding further immigration from the states, and the reckless grants of land to Mexican favourites aroused some ill-feeling, the government on the whole was fairly liberal. The peace party, led by Stephen F. Austin, was able to restrain the more warlike followers of William H. Wharton and Henry Smith (1794–1851) until 1835, when Santa Anna overthrew the federal constitution of 1824 and established a dictatorship. A consultation of representatives from the various settlements met at San Felipe de Austin, October to November 1835. Under Austin's influence the delegates rejected an independence resolution and recommended a union with the Mexican Liberals for the restoration of the constitution of 1824. A provisional government was organized with Henry Smith as governor and James W. Robinson (d. 1853) as lieutenant-governor, Sam Houston as major-general of the armies of Texas; and Austin, Wharton and Branch T. Archer (1790–1858) were elected commissioners to seek aid in the United States. Hostilities had already begun. The Texans routed the Mexicans near Gonzales on the 2nd of October. About a hundred men under Colonel James Bowie and Captain J. W. Fannin defeated a Mexican force near Mission Conception on the 28th of October; and after a campaign of nearly two months Béjar was surrendered to them on the 11th of December.

In the Matamoras expedition the Texan forces were severely crippled on account of a quarrel between Governor Smith, who desired independence, and the majority of his council, who favoured union with the Mexican Liberals. The command was divided between Houston, who was supported by the governor, and two leaders, Frank W. Johnson and J. W. Fannin, who were appointed by the council. The Mexicans under Santa Anna captured the Alamo on the 6th of March 1836 and slaughtered its garrison of 183 men; on the 20th of the same month they captured Fannin and his force of 371 men, and a week later slaughtered all except twenty who escaped. Houston now assumed active command and retreated before Santa Anna until he reached the San Jacinto river, where he dealt the enemy a crushing blow and brought the war to an end; nearly all of Santa Anna's army were killed, wounded or taken prisoners, and even Santa Anna himself was captured the next day, while the Texans lost only two killed and twenty-three wounded. The weakness of the Mexican Liberals and the necessity of securing aid in the States led the Austin party to abandon their opposition to independence. A convention, assembled in the town of Washington on the 1st of March, adopted a declaration of independence on the 2nd and a republican constitution on the 17th. Houston was elected president in September 1836, and the independence of the republic was recognized in 1837 by the United States, Great Britain, France and Belgium. After a long conflict over the slavery question, the state was admitted into the Union under a joint resolution of Congress adopted on the 1st of March 1845,[1] on condition that the United States should settle all questions of boundary with foreign governments, that Texas should retain all of its vacant and unappropriated public lands, and that new states, not exceeding four in number, might be formed within its limits. The western boundary claimed by the republic was the Rio Grande to its source and the meridian of longitude from that point to the forty-second parallel, although as a political division of Mexico its limits never extended farther west than the Nueces and the Medina. The United States government asserted the Rio Grande claim and prepared to enforce it at the cost of war; at the same time the Mexican government considered annexation, regardless of the boundary question, a declaration of war by the United States. An army of 2000 men under Zachary Taylor (*q.v.*) arrived on the north bank of the Rio Grande, opposite Matamoras, on the 28th of March 1846. The Mexican commander, Pedro de Ampudia, demanded Taylor's withdrawal beyond the Nueces within twenty-four hours. He did not obey, and Mariana Arista, Ampudia's successor, opened hostilities. The Americans, outnumbered three to one, defeated the Mexicans in the battles of Palo Alto (May 8th) and Resaca de la Palma (May 9th). The war terminated in the treaty of Guadalupe Hidalgo (February 2, 1848) by which Mexico accepted the Rio Grande boundary. By the Compromise of 1850 Texas received $10,000,000 for its territory lying north and west of a line drawn from the 100th meridian to the Rio Grande, following 36° 30′ N., 103° W. and 32° N. The final step in the determination of the present boundaries of the state was taken in 1896, when the Supreme Court of the United States decided the Greer county case. Under the Florida treaty of 1819–21 a portion of the Red river was to be the northern boundary of Texas east of the 100th meridian, but as there are two branches of the river meeting east of the meridian the enclosed territory (Greer county) was in dispute. The decision of 1896 selected the southern branch and thus deprived Texas of a large tract of fertile land over which it had previously exercised jurisdiction.

In the crisis of 1860–61 Texas sided with the other Southern States in spite of the strong Unionist influence exerted by the German settlers and by Governor Sam Houston. An ordinance of secession was adopted February 1, 1861, and Governor Houston was deposed from office on March 16th. The state was never the scene of active military operations during the Civil War (1861–65), although it is interesting to note that the last battle of the conflict was fought on its soil, at Palmito, near Palo Alto, on the 13th of May 1865, more than a month after the surrender at Appomattox. In conformity with President Johnson's plan of reconstruction, a constitution recognizing the abolition of slavery, renouncing the right of secession, and repudiating the war debt was adopted in 1866, and J. W. Throckmorton, Unionist Democrat, was elected governor. When, in 1867, the Congressional plan of reconstruction was substituted, Texas was joined to Louisiana to constitute the fifth military district, and the first commander, General P. H. Sheridan, removed Throckmorton from office as "an impediment to reconstruction" and appointed E. M. Pease in his place. Delegates to a new constitutional convention were elected in 1868, the constitution framed by this body was ratified in November 1869, state officers and congressmen were elected the same day, the new legislature ratified the Thirteenth and Fourteenth Amendments, and on the 30th of March 1870 Texas was readmitted to the Union. But the state remained under the rule of negroes and carpet-baggers, supported by United States troops until the inauguration of Governor Richard Coke in 1874. It has since been consistently Democratic. The supremacy of the party was threatened for a time by the growth of Populism, but the danger was avoided by the acceptance of free silver, and the partial adoption of the Populist local programme. This surrender aroused strong opposition among the conservative or Cleveland Democrats, which culminated in the Hogg-Clark gubernatorial campaign of 1892. The victory of the Radicals resulted in the establishment of a railway rate commission, based upon a constitutional amendment of 1890 and a statute of 1891, the passage of an alien land law in 1891, which was declared unconstitutional and amended in 1892, the adoption of the Australian ballot system for cities and towns of more than 10,000 inhabitants (1892), the retirement of Roger Q. Mills from the United States Senate (1899) and the sending of free silver delegations to the national conventions of 1896 and 1900.

[1] This acquisition of foreign territory by joint resolution instead of by treaty was followed in the case of Hawaii in 1898.

Governors

Spanish Period (1690–1821)[2]

Domingo Terán de los Rios.
Don Gaspardo de Anaya.
Don Martin de Alarcón.
Marquis San Miguel de Aguayo.
Fernando de Almazan.
Melchior de Mediavilla y Arcona.
Juan Antonio Bustillos y Cevallos.
Manuel de Sandoval.
Carlos de Franquis.
Prudencio de Oribio de Basterra.
Justo Boneo.
Jacinto de Barrios y Jaûrequi.
Antonio de Martos y Navarrete.
Juan Maria Baron de Ripperda.
Domingo Cabello.
Rafael Pacheco.
Manuel Muñoz.
Juan Bautista Elgûezabal.
Antonio Cordero.
Manuel de Salcedo.
Juan Bautista Casas, provisional.
Manuel de Salcedo.
Christoval Dominquez.
Antonio Martinez.

Mexican Period (1821–36)[3]

Trespalacios.
Don Luciana Garcia, provisional.
Rafael Gonzales, provisional.
Victor Blanco.
José Maria Viesca.
José Maria Letona.
Francisco Vidauri y Villaseñor, provisional.
José Maria Goribar, Juan José Elguezebal, } rival claimants.
Augustin Viesca.
Henry Smith, provisional 1835–36

Period of the Republic (1836–46)[4]

David G. Burnet, provisional	1836
Sam Houston	1836–38
Mirabeau B. Lamar	1838–41
Sam Houston	1841–44
Anson Jones	1844–46

BIBLIOGRAPHY.—For general physical description see *Annual Reports of the Texas Geological Survey* (Austin, 1890 sqq.), F. W. Simonds, *Geography of Texas* (New York, 1905), W. L. Bray, *Distribution and Adaptation of the Vegetation of Texas* (Austin, 1905). For economic description see *The Natural Resources and Economic Conditions of the State of Texas* (New York, 1901). On the fauna and flora see Vernon Bailey, *Biological Survey of Texas* (Washington, D.C., 1905) in North American Fauna, No. 25.

On the administration: see the *Constitution of the State of Texas, with Amendments* (Austin, 1891); John and Henry Sayles, *Annotated Civil Statutes of Texas* (2 vols., St Louis, 1897); *The Session Laws*, Twenty-fifth to Twenty-ninth Legislature (Austin, 1897–1905); W. M. Gonge, *The Fiscal History of Texas* (Philadelphia, 1852), for the early financial history; O. M. Roberts in D. G. Wooten's history (see below), ii. 7–325, for an account of legislative and judicial history; and J. J. Lane in Wooten for the educational system. Some valuable statistics will be found in C. W. Raines, *Year-Book for Texas, 1901* (Austin, 1902).

An excellent guide to the history of the state is C. W. Raines, *Bibliography of Texas* (Austin, 1896). The best history of the state is George P. Garrison's *Texas* (Boston and New York, 1903), in the American Commonwealths series, but its treatment of the period since 1845 is too brief. John Henry Brown's *History of Texas from 1685 to 1892* (2 vols., St Louis, 1892) is a detailed, rather biased treatment, by an old Texas pioneer who had access to a large mass of unprinted material. The best of the older works and the basis for subsequent books on the period which it covers is Henderson Yoakum's *History of Texas from its first Settlement in 1685 to its Annexation to the United States in 1846* (2 vols., New York, 1856). See also David B. Edward, *The History of Texas* (Cincinnati, 1836), slightly pro-Mexican in sympathy; H. H. Bancroft, *History of Texas and the North Mexican States* (2 vols., San Francisco, 1884–89), valuable for authorities cited in the footnotes; and H. M. Williams, *Sam Houston and the War of Independence in Texas* (Boston and New York, 1893), the best life of Houston. Dudley G. Wooten (ed.), *A Comprehensive History of Texas, 1685–1897* (2 vols., Dallas, 1898), contains a reprint of Yoakum with notes and several chapters by various writers on Anglo-American colonization, the revolution against Mexico, the land system, the educational system, &c. A series of monographs dealing mostly with the period before 1845 will be found in *The Quarterly of the Texas State Historical Association* (Austin, 1897 sqq.). Among the manuscript treasures at Austin may be mentioned the diplomatic correspondence of the Republic in the state department, the Nacogdoches archives and the W. D. Miller papers in the state library, and the Bexar archives and the Guy M. Bryan (Austin) papers in the university.

TEXT (Lat. *textum*, woven fabric, from *texere*, to weave), a term which is applied with several varieties of meaning to the actual words of an author as written; it is thus used of the original composition as opposed to the commentary, paraphrase, notes, &c., written by others upon it, and to the written printed matter as opposed to the illustrations, diagrams, &c., accompanying it (see TEXTUAL CRITICISM below). A specific meaning is that of a passage of Scripture used as the subject of a sermon or discourse, as an argument or illustration in theological discussion or as a means of edification, exhortation or admonition. Technically the term is also applied to a particular form of writing in MSS. before the age of printing, and so, in composition, in such uses as "text-hand," "text-writer," &c. A "text-book" is a manual or handbook of instruction, such as is used by students as the standard book on the subject which they may be studying.

TEXTILE-PRINTING. "Textile" (see WEAVING) is a general name for all woven fabrics (Lat. *texere*, to weave), and the art of ornamenting such fabrics by printing on designs or patterns in colour is very ancient, probably originating in the East. It has been practised in some form, with considerable success, in China and India from time immemorial, and the Chinese, at least, are known to have made use of engraved wood-blocks many centuries before any kind of printing was known in Europe. That the early Egyptians, too, were acquainted with the art is proved not merely by the writings of Pliny but by the discovery, in the Pyramids and other Egyptian tombs, of fragments of cloth which were undoubtedly decorated by some method of printing.

The Incas of Peru, Chile and Mexico also practised textile-printing previous to the Spanish Invasion in 1519; but, owing to the imperfect character of their records before that date, it is impossible to say whether they discovered the art for themselves, or, in some way, learnt its principles from the Asiatics.

There is no doubt that India was the source from which, by two different channels, Europeans derived their knowledge of block-printing. By land its practice spread slowly westwards through Persia, Asia Minor and the Levant, until it was taken up in Europe—during the latter half of the 17th century. Almost at the same time the French brought directly by sea, from their colonies on the east coast of India, samples of Indian blue and white "resist" prints, and along with them, particulars of the processes by which they had been produced.

I. TECHNOLOGY

Textile-printing was introduced into England in 1676 by a French refugee who opened works, in that year, on the banks of the Thames near Richmond. Curiously enough this is the first print-works on record; but the nationality and political status of its founder are sufficient to prove that printing was previously carried on in France. In Germany, too, textile printing was in all probability well established before it spread to England, for, towards the end of the 17th century, the district of Augsburg was celebrated for its printed linens—a reputation not likely to have been built up had the industry been introduced later than 1676.

On the continent of Europe the commercial importance of calico-printing seems to have been almost immediately recognized, and in consequence it spread and developed there much more rapidly than in England, where it was neglected and practically at a standstill for nearly ninety years after its introduction. During the last two decades of the 17th century and the earlier ones of the 18th new works were started in France, Germany, Switzerland and Austria; but it was only in 1738 that calico-printing was first practised in Scotland, and not until twenty-six years later that Messrs Clayton of Bamber Bridge, near Preston, established in 1764 the first print-works in Lancashire, and thus laid the foundation of what has since become one of the most important industries of the county and indeed of the country. At the present time calico-printing is carried on extensively in every quarter of the globe, and it is pretty safe to say that there is scarcely a civilized country in either hemisphere where a print-works does not exist.

From an artistic point of view most of the pioneer work in calico-printing was done by the French; and so rapid was their advance in this branch of the business that they soon came to be acknowledged as its leading exponents. Their styles of design and schemes of colour were closely followed—even deliberately copied—by all other European printers; and, from the early days of the industry down to the latter half of the 19th century, the productions of the French printers in Jouy, Beauvais, Rouen, Alsace-Lorraine, &c., were looked upon as representing "all that was best" in artistic calico-printing. This reputation was established by the superiority of their *earlier* work, which, whatever else it may have lacked, possessed in a high degree the two main qualities essential to all good decorative work, viz., appropriateness of pattern and excellency of workmanship. If, occasionally, the earlier designers permitted themselves to indulge in somewhat bizarre fancies, they at least carefully refrained from any attempt to produce those pseudo-realistic effects the undue straining after which in later times ultimately led to the degradation of not only French calico-printing design, but of that of all other European nations who followed their lead. The practice of the older craftsmen, at their best, was to treat their ornament in a way at once broad, simple and direct, thoroughly artistic and perfectly adapted to the means by which it had to be reproduced. The result was that their designs were characterized, on the one hand, by those qualities of breadth, flatness of field, simplicity of treatment and pureness of tint so rightly prized by the artist; and, on the other, by their entire freedom from those meretricious effects of naturalistic projection and recession so dear to the modern mind and so utterly opposed to the principles of applied art.

Methods of Printing.

Broadly speaking textile-printing means the local application, to textile fabrics, of any colour in definite patterns or designs, but in properly printed goods the colour becomes part and parcel of the fibre, or, in other words, the latter is dyed so as to resist washing and friction. Textile-printing, then, may be looked upon as a form of dyeing; but, whereas in dyeing proper the whole fabric is uniformly covered with one colour, in printing one or more colours are applied to it in certain parts only, and in sharply defined patterns. In principle these two branches of textile colouring are closely allied, for the colouring matters used in each case are practically identical, but in practice the means whereby their respective objects are attained bear little or no resemblance to each other. In dyeing, for instance, it is sufficient, for the most part, to immerse the fabric in an aqueous solution of the dye-stuff, stirring it about constantly or otherwise manipulating it to prevent unevenness. In printing, however, the colour must be applied by special means—either by a wooden block, a stencil or engraved plates, or rollers—and thickened to prevent it from spreading, by capillary attraction, beyond the limits of the pattern or design. Many colours also contain, besides the colouring matter and thickening, all the substances necessary for their proper fixation on the cloth when the latter is simply passed through a subsequent process of steaming, and others again require to be subjected to many after treatments before they are thoroughly developed and rendered fast to light and washing.

There are five distinct methods at present in use for producing coloured patterns on cloth:—

(1) Hand block-printing.

(2) Perrotine or block-printing by machine.

(3) Engraved plate-printing.

(4) Engraved roller-printing.

(5) Stencilling, which although not really a printing process may be classed here as one.

(1) *Hand Block-Printing.*—This process, though considered by some to be the most artistic, is the earliest, simplest and slowest of all methods of printing.

The blocks may be made of box, lime, holly, sycamore, plane or pear wood, the latter three being most generally employed. They vary in size considerably, but must always be between two and three inches thick, otherwise they are liable to warp—a defect which is additionally guarded against by backing the wood chosen with two or more pieces of cheaper wood, such as deal or pine. The several pieces or blocks are tongued and grooved to fit each other, and are then securely glued together, under pressure, into one solid block with the grain of each alternate piece running in a different direction.

The block, being planed quite smooth and perfectly flat, next has the design drawn upon, or transferred to it. This latter is effected by rubbing off, upon its flat surface, a tracing in lamp-black and oil, of the outlines of the masses of the design. The portions to be left in relief are then tinted, between their outlines, in ammoniacal carmine or magenta, for the purpose of distinguishing them from those portions which have to be cut away. As a separate block is required for each distinct colour in the design, a separate tracing must be made of each and transferred (or "put on" as it is termed) to its own special block.

Having thus received a tracing of the pattern the block is thoroughly damped and kept in this condition by being covered with wet cloths during the whole process of "cutting." The block-cutter commences by carving out the wood around the heavier masses first, leaving the finer and more delicate work until the last so as to avoid any risk of injuring it during the cutting of the coarser parts. When large masses of colour occur in a pattern, the corresponding parts on the block are usually cut in outline, the object being filled in between the outlines with felt, which not only absorbs the colour better, but gives a much more even impression than it is possible to obtain with a large surface of wood. When finished, the block presents the appearance of flat relief carving, the design standing out like letterpress type.

Fine details are very difficult to cut in wood, and, even when successfully cut, wear down very rapidly or break off in printing. They are therefore almost invariably built up in strips of brass or copper, bent to shape and driven edgewise into the flat surface of the block. This method is known as "coppering," and by its means many delicate little forms, such as stars, rosettes and fine spots can be printed, which would otherwise be quite impossible to produce by hand or machine block-printing.

Frequently, too, the process of "coppering" is used for the purpose of making a mould, from which an entire block can be made and duplicated as often as desired, by casting. In this case the metal strips are driven to a predetermined depth into the face of a piece of lime-wood cut across the grain, and, when the whole design is completed in this way, the block is placed, metal face downwards, in a tray of molten type-metal or solder, which transmits sufficient heat to the inserted portions of the strips of copper to enable them to carbonize the wood immediately in contact with them and, at the same time, firmly attaches itself to the outstanding portions. When cold a slight tap with a hammer on the back of the lime-wood block easily detaches the cake of the type-metal or alloy and along with it, of course, the strips of copper to which it is firmly soldered, leaving a matrix, or mould, in wood of the original design. The casting is made in an alloy of low melting-point, and, after cooling, is filed or ground until all its projections are of the same height and perfectly smooth, after which it is screwed on to a wooden support and is ready for printing. Similar moulds are also made by burning out the lines of the pattern with a red-hot steel punch, capable of being raised or lowered at will, and under which the block is moved about by hand along the lines of the pattern.

In addition to the engraved block, a printing table and colour sieve are required. The table consists of a stout framework of wood or iron supporting a thick slab of stone varying in size according to the width of cloth to be printed. Over the stone table top a thick piece of woollen printer's blanket is tightly stretched to supply the elasticity necessary to give the block every chance of making a good impression on the cloth. At one end, the table is provided with a couple of iron brackets to carry the roll of cloth to be printed and, at the other, a series of guide rollers, extending to the ceiling, are arranged for the purpose of suspending and drying the newly printed goods. The "colour sieve" consists of a tub (known as the swimming tub) half filled with starch paste, on the surface of which floats a frame covered at the bottom with a tightly-stretched piece of mackintosh or oiled calico. On this the "colour sieve" proper, a frame similar to the last but covered with fine woollen cloth, is placed, and forms when in position a sort of elastic colour trough over the bottom of which the colour is spread evenly with a brush.

The *modus operandi* of printing is as follows:—The printer commences by drawing a length of cloth, from the roll, over the table, and marks it with a piece of coloured chalk and a ruler to indicate where the first impression of the block is to be applied. He then applies his block in two different directions to the colour on the sieve and finally presses it firmly and steadily on the cloth, ensuring a good impression by striking it smartly on the back with a wooden mallet. The second impression is made in the same way, the printer taking care to see that it fits exactly to the first, a point which he can make sure of by means of the pins with which the blocks are provided at each corner and which are arranged in such a way that when those at the right side or at the top of the block fall upon those at the left side or the bottom of the previous impression the two printings join up exactly and continue the pattern without a break. Each succeeding impression is made in precisely the same manner until the length of cloth on the table is fully printed. When this is done it is wound over the drying rollers, thus bringing forward a fresh length to be treated similarly.

If the pattern contains several colours the cloth is usually first printed throughout with one, then dried, re-wound and printed with the second, the same operations being repeated until all the colours are printed.

Many modifications of block-printing have been tried from time to time, but of these only two—"tobying" and "rainbowing"—are of any practical value. The object of "tobey-printing" is to print the several colours of a multicolour pattern at one operation, and for this purpose a block with the whole of the pattern cut upon it, and a specially constructed "colour sieve" are employed. The sieve consists of a thick block of wood, on one side of which a series of compartments are hollowed out, corresponding roughly in shape, size and position to the various objects cut on the block. The tops of the dividing walls of these compartments are then coated with melted pitch, and a piece of fine woollen cloth is stretched over the whole and pressed well down on the pitch so as to adhere firmly to the top of each wall; finally a piece of string soaked in pitch is cemented over the woollen cloth along the lines of the dividing walls, and after boring a hole through the bottom of each compartment the sieve is ready for use. In operation each compartment is filled with its special colour through a pipe connecting it with a colour box situated at the side of the sieve and a little above it, so as to exert just sufficient pressure on the colour to force it gently through the woollen cloth, but not enough to cause it to overflow its proper limits, formed by the pitch-soaked string boundary lines.

The block is then carefully pressed on the sieve, and, as the different parts of its pattern fall on different parts of the sieve, each takes up a certain colour which it transfers to the cloth in the usual way. By this method of "tobying" from two to six colours may be printed at one operation, but it is obvious that it is only applicable to patterns where the different coloured objects are placed at some little distance apart, and that, therefore, it is of but limited application.

Block-printing by hand is a slow process; it is, however, capable of yielding highly artistic results, some of which are unobtainable by any other means, and it is, therefore, still largely practised for the highest class of work in certain styles.

(2) *Perrotine-Printing.*—The "perrotine" is a block-printing machine invented by Perrot of Rouen in 1834, and practically speaking is the only successful mechanical device ever introduced for this purpose. For some reason or other it has rarely been used in England, but its value was almost immediately recognized on the Continent, and although block-printing of all sorts has been replaced to such an enormous extent by roller-printing, the "perrotine" is still largely employed in French, German and Italian works.

The construction of this ingenious machine is too complex to describe here without the aid of several detailed drawings, but its mode of action is roughly as follows:—Three large blocks (3 ft. long by 3 to 5 in. wide), with the pattern cut or cast on them in relief, are brought to bear successively on the three faces of a specially constructed printing table over which the cloth passes (together with its backing of printer's blanket) after each impression. The faces of the table are arranged at right angles to each other, and the blocks work in slides similarly placed, so that their engraved faces are perfectly parallel to the tables. Each block is moreover provided with its own particular colour trough, distributing brush, and woollen colour pad or sieve, and is supplied automatically with colour by these appliances during the whole time that the machine is in motion. The first effect of starting the machine is to cause the colour sieves, which have a reciprocating motion, to pass over, and receive a charge of colour from the rollers, fixed to revolve, in the colour troughs. They then return to their original position between the tables and the printing blocks, coming in contact on the way with the distributing brushes, which spread the colour evenly over their entire surfaces. At this point the blocks advance and are gently pressed twice against the colour pads (or sieves) which then retreat once more towards the colour troughs. During this last movement the cloth to be printed is drawn forward over the first table, and, immediately the colour pads are sufficiently out of the way, the block advances and, with some force, stamps the first impression on it. The second block is now put into gear and the foregoing operations are repeated for both blocks, the cloth advancing, after each impression, a distance exactly equal to the width of the blocks. After the second block has made its impression the third comes into play in precisely the same way, so that as the cloth leaves the machines it is fully printed in three separate colours, each fitting into its proper place and completing the pattern. If necessary the forward movement of the cloth can be arrested without in any way interfering with the motion of the blocks—an arrangement which allows any insufficiently printed impression to be repeated in exactly the same place with a precision practically impossible in hand-printing.

For certain classes of work the "perrotine" possesses great advantages over the hand-block; for not only is the rate of production greatly increased, but the joining up of the various impressions to each other is much more exact—in fact, as a rule, no sign of a break in continuity of line can be noticed in well-executed work. On the other hand, however, the "perrotine" can only be applied to the production of patterns containing not more than three colours nor exceeding five inches in vertical repeat, whereas hand block-printing can cope with patterns of almost any scale and containing any number of colours. All things considered, therefore, the two processes cannot be compared on the same basis: the "perrotine" is best for work of a utilitarian character and the hand-block for decorative work in which the design only repeats every 15 to 20 in. and contains colours varying in number from one to a dozen.

(3) *Engraved Copperplate-Printing.*—The printing of textiles from engraved copperplates was first practised by Bell in 1770. It is now entirely obsolete, as an industry, in England, and is only mentioned here because it is, to a slight extent, still used in Switzerland for printing finely engraved borders on a special style of handkerchief the centre of which is afterwards filled in by block-printing.

The presses first used were of the ordinary letterpress type, the engraved plate being fixed in the place of the type. In later improvements the well-known cylinder press was employed; the plate was inked mechanically and cleaned off by passing under a sharp blade of steel; and the cloth, instead of being laid on the plate, was passed round the pressure cylinder. The plate was raised into frictional contact with the cylinder and in passing under it transferred its ink to the cloth.

The great difficulty in plate-printing was to make the various impressions join up exactly; and, as this could never be done with any certainty, the process was eventually confined to patterns complete in one repeat, such as handkerchiefs, or those made up of widely separated objects in which no repeat is visible, like, for instance, patterns composed of little sprays, spots, &c.

(4) *Roller-Printing, Cylinder-Printing, or Machine-Printing.*—This elegant and efficient process was patented and worked by Bell in 1785 only fifteen years after his application of the engraved plate to textiles. It will probably remain a moot question as to whether he was the originator of the idea, but it is beyond doubt that he was the first man to put into practice the continuous printing of cloth from engraved copper rollers. Bell's first patent was for a machine to print six colours at once, but, owing probably to its incomplete development, this was not immediately successful, although the principle of the method was shown to be practical by the printing of one colour with perfectly satisfactory results. The difficulty was to keep the six rollers, each carrying a portion of the pattern, in perfect register with each other. This defect was soon overcome by Adam Parkinson of Manchester, and in 1785, the year of its invention, Bell's machine with Parkinson's improvement was successfully employed by Messrs Livesey, Hargreaves, Hall & Co., of Bamber Bridge, Preston, for the printing of calico in from two to six colours at a single operation.

What Parkinson's contribution to the development of the modern roller-printing machine really was is not known with certainty, but it was possibly the invention of the delicate adjustment known as "the box wheel," whereby the rollers can be turned, whilst the machine is in motion, either in or against the direction of their rotation.

In its simplest form the roller-printing machine consists of a strong cast iron cylinder mounted in adjustable bearings capable of sliding up and down slots in the sides of the rigid iron framework. Beneath this cylinder the engraved copper roller rests in stationary bearings and is supplied with colour from a wooden roller which revolves in a colour-box below it. The copper roller is mounted on a stout steel axle, at one end of which a cog-wheel is fixed to gear with the driving wheel of the machine, and at the other end a smaller cog-wheel to drive the colour-furnishing roller. The cast iron pressure cylinder is wrapped with several thicknesses of a special material made of wool and cotton—lapping—the object of which is to provide the elasticity necessary to enable it to properly force the cloth to be printed into the lines of engraving. A further and most important appliance is the "doctor"—a thin sharp blade of steel which rests on the engraved roller and serves to scrape off every vestige of superfluous colour from its surface, leaving only that which rests in the engraving. On the perfect action of this "doctor" depends the entire success of printing, and as its sharpness and angle of inclination to the copper roller varies with the styles of work in hand it requires an expert to "get it up" (sharpen it) properly and considerable practical experience to know exactly what qualities it should possess in any given case. In order to prevent it (the "doctor") from wearing irregularly it is given a to-and-fro motion so that it is constantly changing its position and is never in contact with one part of the engraving for more than a moment at a time. A second "doctor" of brass or a similar alloy is frequently added on the opposite side of the roller to that occupied by the steel or "cleaning" doctor; it is known technically as the "lint doctor" from its purpose of cleaning off loose filaments or "lint" which the roller picks off the cloth during the printing operation. The steel or "cleaning doctor" is pressed against the roller by means of weighted levers, but the "lint doctor" is usually just allowed to rest upon it by its own weight as its function is merely to intercept the nap which becomes detached from the cloth and would, if not cleaned from the roller, mix with the colour and give rise to defective work.

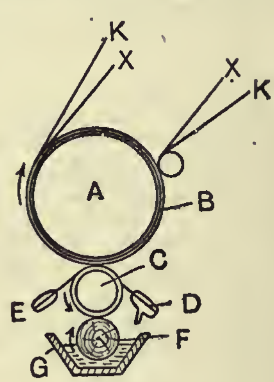

FIG. 1.

The working of the machine will be best understood by referring to the accompanying diagrammatic sketch of a single colour (fig. 1).

A is the cast iron pressure cylinder; B the lapping with which it is usually wrapped; C the engraved copper printing roller; D the steel "cleaning doctor"; E the brass "lint doctor"; F the colour-furnishing roller; G the colour-trough or "box" in which the latter (F) works partly immersed in colour; X an endless woollen blanket continually circulating between the cloth to be printed (K) and the cylinder A; and K the cloth in question. In operation, the cylinder A is screwed down with an even pressure into frictional contact with the roller C; the machine is then set in motion, turning in the direction indicated by the arrows; the cloth is now introduced between A and C and as it leaves the machine fully printed it is carried over a series of drying cylinders situated above and heated by steam. The printing roller C is the only part of the machine directly connected with the motor or main drive of the works through the cog-wheel on its axle—the "mandril"—all the other parts deriving their motion from *it*, either by friction as in the case of the cylinder or by a spur wheel as in that of the colour-furnishing roller. The mode of printing is almost self-evident; the roller C revolving in the direction of the arrow takes colour from the "furnisher" F, the excess is scraped off by the "doctor" G and, in continuing its course, it comes in contact with the cloth K, which being pressed by the cylinder A into the engraving abstracts the colour therefrom and of course receives an exact impression of the engraved pattern.

Larger machines printing from two to sixteen colours are precisely similar in principle to the above, but differ somewhat in detail and are naturally more complex and difficult to operate. In a twelve-colour machine, for example, twelve copper rollers, each carrying one portion of the design, are arranged round a central pressure cylinder, or bowl, common to all, and each roller is driven by a common driving wheel, called the "crown" wheel, actuated, in most cases, by its own steam-engine or motor. Another difference is that the adjustment of pressure is transferred from the cylinder to the rollers which work in specially constructed bearings capable of the following movements: (1) Of being screwed up bodily until the rollers are lightly pressed against the central bowl; (2) of being moved to and fro sideways so that the rollers may be laterally adjusted; and (3) of being moved up or down for the purpose of adjusting the rollers in vertical direction. Notwithstanding the great latitude of movement thus provided each roller is furnished with a "box-wheel," which serves the double purpose of connecting or gearing it to the driving wheel, and of affording a fine adjustment. Each roller is further furnished with its own colour-box and doctors.

With all these delicate equipments at his command a machine-printer is enabled to fit all the various parts of the most complicated patterns with an ease, despatch and precision which are remarkable considering the complexity and size of the machine.

In recent years many improvements have been made in printing machines and many additions made to their already wonderful capacities. Chief amongst these are those embodied in the "Intermittent" and the "Duplex" machines. In the former any or all of the rollers may be moved out of contact with the cylinder at will, and at certain intervals. Such machines are used in the printing of shawls and "sarries" for the Indian market. Such goods require a wide border right across their width at varying distances—sometimes every three yards, sometimes every nine yards—and it is to effect this, with rollers of ordinary dimensions, that "intermittent" machines are used. The body of the "sarrie" will be printed, say for six yards with eight rollers; these then drop away from the cloth and others, which have up to then been out of action, immediately fall into contact and print a border or "crossbar," say one yard wide, across the piece; they then recede from the cloth and the first eight again return and print another six yards, and so on continually.

The "Duplex" or "Reversible" machine derives its name from the fact that it prints both sides of the cloth. It consists really of two ordinary machines so combined that when the cloth passes, fully printed on one side from the first, its plain side is exposed to the rollers of the second, which print an exact duplicate of the first impression upon it in such a way that both printings coincide. A pin pushed through the face of the cloth ought to protrude through the corresponding part of the design printed on the back if the two patterns are in good "fit."

The advantages possessed by roller-printing over all other processes are mainly three: firstly, its high productivity—10,000 to 12,000 yds. being commonly printed in one day of ten hours by a single-colour machine; secondly, by its capacity of being applied to the reproduction of every style of design, ranging from the fine delicate lines of copperplate engraving and the small "repeats" and limited colours of the "perrotine" to the broadest effects of block-printing and to patterns varying in "repeat" from 1 to 80 in.; and thirdly, the wonderful exactitude with which each portion of an elaborate multicolour pattern can be fitted into its proper place, and the entire absence of faulty joints at its points of "repeat" or repetition—a consideration of the utmost importance in fine delicate work, where such a blur would utterly destroy the effect.

(5) *Stencilling.*—The art of stencilling is very old. It has been applied to the decoration of textile fabrics from time immemorial by the Japanese, and, of late years, has found increasing employment in Europe for certain classes of decorative work on woven goods for furnishing purposes.

The pattern is cut out of a sheet of stout paper or thin metal with a sharp-pointed knife, the uncut portions representing the part that is to be "reserved" or left uncoloured. The sheet is now laid on the material to be decorated and colour is brushed through its interstices.

It is obvious that with suitable planning an "all over" pattern may be just as easily produced by this process as by hand or machine printing, and that moreover, if several plates are used, as many colours as plates may be introduced into it. The peculiarity of stencilled patterns is that they have to be held together by "ties," that is to say, certain parts of them have to be left uncut, so as to connect them with each other, and prevent them from falling apart in separate pieces. For instance, a complete circle cannot be cut without its centre dropping out, and, consequently, its outline has to be interrupted at convenient points by "ties" or uncut portions. Similarly with other objects. The necessity for "ties" exercises great influence on the design, and in the hands of a designer of indifferent ability they may be very unsightly. On the other hand, a capable man utilizes them to supply the drawing, and when thus treated they form an integral part of the pattern and enhance its artistic value whilst complying with the conditions and the process.

For single-colour work a stencilling machine was patented in 1894 by S. H. Sharp. It consists of an endless stencil plate of thin sheet steel which passes continuously over a revolving cast iron cylinder. Between the two the cloth to be ornamented passes and the colour is forced on to it, through the holes in the stencil, by mechanical means.

(6) *Other Methods of Printing.*—Although most work is executed throughout by one or other of the five distinct processes mentioned above, combinations of them are not infrequently employed. Sometimes a pattern is printed partly by machine and partly by block; and sometimes a cylindrical block is used along with engraved copper-rollers in the ordinary printing machine. The block in this latter case is in all respects, except that of shape, identical with a flat wood or "coppered" block, but, instead of being dipped in colour, it receives its supply from an endless blanket, one part of which works in contact with colour-furnishing rollers and the other part with the cylindrical block. This block is known as a "surface" or "peg" roller. Many attempts have been made to print multicolour patterns with "surface" rollers alone, but hitherto with little success, owing to their irregularity in action and to the difficulty of preventing them from warping. These defects are not present in the printing of linoleum in which opaque oil colours are used—colours which neither sink into the body of the hard linoleum nor tend to warp the roller.

The printing of yarns and warps is extensively practised. It is usually carried on by a simple sort of "surface" printing machine and calls for no special mention.

Lithographic printing, too, has been applied to textile fabrics with somewhat qualified success. Its irregularity and the difficulty of printing "all over" patterns to "repeat" properly, have restricted its use to the production of decorative panels, equal in size to that of the plate or stone, and complete in themselves.

Engraving of Copper Rollers

The engraving of copper rollers is one of the most important branches of textile-printing and on its perfection of execution depends, in great measure, the ultimate success of the designs. Roughly speaking, the operation of engraving is performed by three different methods, viz. (1) By hand with a graver which cuts the metal away; (2) by etching, in which the pattern is dissolved out in nitric acid; and (3) by machine, in which the pattern is simply indented.

(1) Engraving by hand is the oldest and most obvious method of engraving, but is the least used at the present time on account of its slowness. The design is transferred to the roller from an oil-colour tracing and then merely cut out with a steel graver, prismatic in section, and sharpened to a bevelled point. It requires great steadiness of hand and eye, and although capable of yielding the finest results it is only now employed for very special work and for those patterns which are too large in scale to be engraved by mechanical means.

(2) In the etching process an enlarged image of the design is cast upon a zinc plate by means of an enlarging camera and prisms or reflectors. On this plate it is then painted in colours roughly approximating to those in the original, and the outlines of each colour are carefully engraved in duplicate by hand. The necessity for this is that in subsequent operations the design has to be again reduced to its original size and, if the outlines on the zinc plate were too small at first, they would be impracticable either to etch or print. The reduction of the design and its transfer to a varnished copper roller are both effected at one and the same operation in the pantograph machine. This machine is capable of reducing a pattern on the zinc plate from one-half to one-tenth

of its size, and is so arranged that when its pointer or "stylus" is moved along the engraved lines of the plate a series of diamond points cut a reduced facsimile of them through the varnish with which the roller is covered. These diamond points vary in number according to the number of times the pattern is required to repeat along the length of the roller. Each colour of a design is transferred in this way to a separate roller. The roller is then placed in a shallow trough containing nitric acid, which acts only on those parts of it from which the varnish has been scraped. To ensure evenness the roller is revolved during the whole time of its immersion in the acid. When the etching is sufficiently deep the roller is washed, the varnish dissolved off, any parts not quite perfect being retouched by hand.

(3) In machine engraving the pattern is impressed in the roller by a small cylindrical "mill" on which the pattern is in relief. It is an indirect process and requires the utmost care at every stage. The pattern or design is first altered in size to repeat evenly round the roller. One repeat of this pattern is then engraved by hand on a small highly polished soft steel roller, usually about 3 in. long and ½ in. to 3 in. in diameter; the size varies according to the size of the "repeat" with which it must be identical. It is then repolished, painted with a chalky mixture to prevent its surface oxidizing and exposed to a red-heat in a box filled with chalk and charcoal; then it is plunged in cold water to harden it and finally tempered to the proper degree of toughness. In this state it forms the "die" from which the "mill" is made. To produce the actual "mill" with the design in relief a softened steel cylinder is screwed tightly against the hardened die and the two are rotated under constantly increasing pressure until the softened cylinder or "mill" has received an exact replica in *relief* of the engraved pattern. The "mill" in turn is then hardened and tempered, when it is ready for use. In size it may be either exactly like the "die" or its circumferential measurement may be any multiple of that of the latter according to circumstances.

The copper roller must in like manner have a circumference equal to an exact multiple of that of the "mill," so that the pattern will join up perfectly without the slightest break in line.

The *modus operandi* of engraving is as follows:—The "mill" is placed in contact with one end of the copper roller, and being mounted on a lever support as much pressure as required can be put upon it by adding weights. Roller and "mill" are now revolved together, during which operation the projection parts of the latter are forced into the softer substance of the roller, thus engraving it, in intaglio, with several replicas of what was cut on the original "die." When the full circumference of the roller is engraved, the "mill" is moved sideways along the length of the roller to its next position, and the process is repeated until the whole roller is fully engraved.

Preparation of Cloth for Printing

Goods intended for calico-printing ought to be exceptionally well bleached, otherwise mysterious stains, and other serious defects, are certain to arise during subsequent operations. Particulars of bleaching will be found in the article Bleaching (*q.v.*).

The chemical preparations used for special styles will be mentioned in their proper places; but a general "prepare," employed for most colours that are developed and fixed by steaming only, consists in passing the bleached calico through a weak solution of "sulphated" or turkey red oil containing from 2½ per cent. to 5 per cent. of fatty acid. Some colours are printed on pure bleached cloth, but all patterns containing alizarine red, rose and salmon shades, are considerably brightened by the presence of oil, and indeed very few, if any, colours are detrimentally affected by it.

Apart from wet preparations the cloth has always to be brushed, to free it from loose nap, flocks and dust which it picks up whilst stored. Frequently, too, it has to be "sheared" by being passed over rapidly revolving knives arranged spirally round an axle, which rapidly and effectually cuts off all filaments and knots, leaving the cloth perfectly smooth and clean and in a condition fit to receive impressions of the most delicate engraving. Some figured fabrics, especially those woven in checks, stripes and "cross-overs," require very careful stretching and straightening on a special machine, known as a "stenter," before they can be printed with certain formal styles of pattern which are intended in one way or another to correspond with the cloth pattern. Finally, all descriptions of cloth are wound round hollow wooden or iron centres into rolls of convenient size for mounting on the printing machines.

Preparation of Colours

The art of making colours for textile-printing demands both chemical knowledge and extensive technical experience, for their ingredients must not only be properly proportioned to each other, but they must be specially chosen and compounded for the particular style of work in hand. For a pattern containing only one colour any mixture whatever may be used so long as it fulfils all conditions as to shade, quality and fastness; but where two or more colours are associated in the same design each must be capable of undergoing without injury the various operations necessary for the development and fixation of the others.

All printing pastes whether containing colouring matter or not are known technically as "colours," and are referred to as such in the sequence.

Colours vary considerably in composition. The greater number of them contain all the elements necessary for the direct production and fixation of the colour-lake. Some few contain the colouring matter alone and require various after-treatments for its fixation; and others again are simply "mordants" thickened. A mordant is the metallic salt or other substance which combines with the colouring principle to form an insoluble colour-lake, either directly by steaming, or indirectly by dyeing.

All printing colours require to be thickened, for the twofold object of enabling them to be transferred from colour-box to cloth without loss and to prevent them from "running" or spreading beyond the limits of the pattern.

Thickening Agents.—The thickening agents in most general use as vehicles in printing, are starch, flour, gum arabic, gum senegal and gum tragacanth, British gum or dextrine and albumen.

With the exception of albumen all these are made into pastes, or dissolved, by boiling in double or "jacketed" pans, between the inner and outer casings of which either steam or water may be made to circulate, for boiling and cooling purposes. Mechanical agitators are also fitted in these pans to mix the various ingredients together, and to prevent the formation of lumps by keeping the contents thoroughly stirred up during the whole time they are being boiled and cooled.

Starch Paste.—This is made by mixing 15 ℔ of wheat starch with a little cold water to a smooth creamy paste; a little olive oil is then added and sufficient water to bring the whole up to 10 gallons. The mixture is then thickened by being boiled for about an hour and, after cooling, is ready for use.

Starch is the most extensively used of all the thickenings. It is applicable to all but strongly alkaline or strongly acid colours. With the former it thickens up to a stiff unworkable jelly, while mineral acids or acid salts convert it into dextrine, thus diminishing its thickening power. Acetic and formic acids have no action on it even at the boil.

Flour paste is made in a similar way to starch paste. At the present time it is rarely used for anything but the thickening of aluminium and iron mordants, for which it is eminently adapted.

Gum arabic and gum senegal are both very old thickenings, but their expense prevents them from being used for any but pale delicate tints. They are especially useful thickenings for the light ground colours of soft muslins and sateens on account of the property they possess of dissolving completely out of the fibres of the cloth in the washing process after printing. Starch and artificial gums always leave the cloth somewhat harsh in "feel" unless they are treated specially, and are moreover incapable of yielding the beautifully clear and perfectly even tints resulting from the use of natural gums. Very dark colours cannot well be obtained with gum senegal or gum arabic thickenings; they come away too much in washing, the gum apparently preventing them from combining fully with the fibres. Stock solutions of these two gums are usually made by dissolving 6 or 8 ℔ of either in one gallon of water, either by boiling or in the cold by standing.

British gum or dextrine is prepared by heating starch. It varies considerably in composition—sometimes being only slightly roasted and consequently only partly converted into dextrine, and at other times being highly torrefied, and almost completely soluble in cold water and very dark in colour. Its thickening power decreases and its "gummy" nature increases as the temperature at which it is roasted is raised. The lighter coloured gums or dextrines will make a good thickening with from 2 to 3 ℔ of gum to one gallon of water, but the darkest and most highly calcined require from 6 to 10 ℔ per gallon to give a substantial paste. Between these limits all qualities are obtainable. The darkest qualities are very useful for strongly acid colours, and with the exception of gum senegal, are the best for strongly alkaline colours and discharges.

Like the natural gums, neither light nor dark British gums penetrate into the fibre of the cloth so deeply as pure starch or flour, and are therefore unsuitable for very dark strong colours.

Gum tragacanth, or "Dragon," is one of the most indispensable thickening agents possessed by the textile printer. It may be mixed in any proportion with starch or flour and is equally useful for pigment colours and mordant colours. When added to starch paste it increases its penetrative power, adds to its softness without diminishing its thickness, makes it easier to wash out of the fabric and produces much more level colours than starch paste alone. Used by itself it is suitable for printing all kinds of dark grounds on goods which are required to retain their soft clothy feel. A tragacanth mucilage may be made either by allowing it to stand a day or two in contact with cold water or by soaking it for twenty-four hours in warm water and then boiling it up until it is perfectly smooth and homogeneous. If boiled under pressure it gives a very fine smooth mucilage (not a solution proper), much thinner than if made in the cold.

Albumen.—Albumen is both a thickening and a fixing agent for insoluble pigments such as chrome yellow, the ochres, vermilion and ultramarine. Albumen is always dissolved in the cold, a process which takes several days when large quantities are required. The usual strength of the solution is 4 ℔ per gallon of water for blood albumen, and 6 ℔ per gallon for egg albumen. The latter is expensive and only used for the lightest shades. For most purposes one part of albumen solution is mixed with one part of tragacanth mucilage, this proportion of albumen being found amply sufficient for the fixation of all ordinary pigment colours. In special instances the blood albumen solution is made as strong as 50 per cent., but this is only in cases where very dark colours are required to be absolutely fast to washing. After printing, albumen-thickened colours are exposed to hot steam, which coagulates the albumen and effectually fixes the colours.

Formerly colours were always prepared for printing by boiling the thickening agent, the colouring matter and solvents, &c., together, then cooling and adding the various fixing agents. At the present time, however, concentrated solutions of the colouring matters and other adjuncts are often simply added to the cold thickenings, of which large quantities are kept in stock.

Colours are reduced in shade by simply adding more starch or other paste. For example, a dark blue containing 4 oz. of methylene blue per gallon may readily be made into a pale shade by adding to it thirty times its bulk of starch paste or gum, as the case may be. Similarly with other colours.

Before printing it is very essential to strain or sieve all colours in order to free them from lumps, fine sand, &c., which would inevitably damage the highly polished surface of the engraved rollers and result in bad printing. Every scratch on the surface of a roller prints a fine line in the cloth, and too much care, therefore, cannot be taken to remove, as far as possible, all grit and other hard particles from every colour.

The straining is usually done by squeezing the colour through fine cotton or silk cloths. Mechanical means are also employed for colours that are used hot or are very strongly alkaline or acid.

Styles of Printing

The widely differing properties of the hundreds of colouring matters now on the market give rise to many different styles of textile-printing. Generally speaking, these fall into the following four great divisions:—

(1) Direct printing.
(2) The printing of a mordant upon which the colour is afterwards dyed.
(3) The discharge style.
(4) The resist or reserve style.

The fact that each of these divisions is further sub-divided into many smaller divisions renders it out of the question to give more than a few typical examples of the various styles they include.

(1) *Direct Printing.*—This style is capable of application to almost every class of colour known. Its essential feature is that the colouring matter and its fixing agent are both applied to the fabric simultaneously. In some instances the fabric requires to be previously prepared for certain of the colours used along with those characteristic of the process; but this is one of many cases where two styles are combined, and it must be classed with the one which it most resembles.

(*a*) *Application of Mordant Dye-Stuffs.*—Mordant colours include both artificial and natural dye-stuffs (see also under Dyeing), the most important of all being *alizarine*, an artificial preparation of the colouring-principle of the madder root. With different metallic oxides alizarine forms different colour-lakes all exceedingly fast to light and soap. Aluminium mordant gives red and pink lakes; iron mordant, purples and lavenders; chromium yields maroons; and uranium gives grey shades. Mixture of iron and aluminium produce various tones of chocolate and brown.

In addition to alizarine the following are a few of the more important mordant dye-stuffs employed in textile-printing:—

Alizarine orange with aluminium and chrome mordants for orange and warm brown shades respectively; alizarine bordeaux, with alumina, for violets; alizarine blue with chrome and zinc for quiet blue shades; coeruleine and alizarine viridine for greens and olives with chromium mordants; gallocyanine, chrome violet blue, alizarine cyanines, &c., with chromium for various shades of blue and violet; alizarine yellows and anthracene brown for yellows and fawn shades respectively with either aluminium or chrome mordants. The natural dye-stuffs belonging to this series are chiefly: logwood, with chromium and iron mordants, for blacks; Persian berries and quercitron bark, with aluminium, tin and chromium mordants, for colours ranging from brilliant yellow to quiet old golds and browns; catechu, with chromium, for very fast dark browns; and, occasionally, in mixtures, sapan-wood, peach-wood, Brazil-wood, and divi-divi extracts with any of the above-mentioned mordants.

The mordants are mostly in the form of acetates which are stable in the cold but decompose during the steaming process, and combine as hydroxides with the colours, forming and fixing on the fabric the insoluble lake.

Alizarine reds and pinks are the most complicated of the mordant colours, requiring for their proper production the addition of brightening agents, such as oxalate of tin, oils, tartaric acid, and also acetate of lime. This also applies to alizarine orange, but all the other colours are very simple to compound and are stable for a long time after making. Reds, pinks and oranges are best prepared freshly each day; their constituents are liable to combine if the colour stands twenty-four hours before printing.

The following types of recipes will give some idea of the way in which colours are mixed:—

Red. 6½ gallons thick starch and tragacanth paste.
1¼ ,, alizarine (20 per cent. commercial paste).
1 ,, nitrate of alumina, 18° Tw.
½ ,, acetate of lime, 28° Tw.
¼ ,, oxalate of tin, 10° Tw.
½ ,, 10 per cent. solution of tartaric acid.

Pink. 6½ gallons starch-tragacanth paste.
1 ,, blue shade alizarine (20 per cent. paste).
1¼ ,, sulphocyanide of alumina, 18° Tw.
⅜ ,, acetate of lime, 28° Tw.
¼ ,, oxalate of tin.
½ ,, citrate of alumina, 40° Tw.

For reds and pinks the nitrate, sulphocyanide and citrate of alumina are generally preferred in practice to the acetate though the latter is also largely used. Oranges from alizarine orange are made similarly.

Purple. 9⅛ gallons starch paste.
⅛ ,, blue shade alizarine, 20 per cent.
½ ,, acetic acid.
⅛ ,, acetate of lime, 28° Tw.
⅛ ,, acetate of iron, 24° Tw.

Maroon. 5½ gallons paste.
1 ,, alizarine, 20 per cent.
¾ ,, acetate of chrome, 32° Tw.
⅜ ,, acetate of lime, 28° Tw.

Blues and the other colours are made by leaving out the lime in the last recipe and replacing the alizarine with another colour.

Alizarine Blue. ½ ℔ alizarine blue shade (powd.).
(*Light Shade.*) 1 gallon water.
3½ ,, thick paste.
1½ ,, acetate of chrome, 40° Tw.

Logwood and other natural colours are specially boiled.

Logwood Black.
15 ℔ starch.
10 ,, British gum.
4½ gallons water.
¾ ,, acetic acid.
1½ ,, logwood extract, 48° Tw.
⅜ ,, quercitron extract, 48° Tw.

Boil, cool and add:—
½ ℔ red prussiate of potash.
¼ gallon water.
2 ,, acetate of chrome, 40° Tw.
2 oz. chlorate of potash.

Quercitron Yellow. 1½ gallons quercitron extract, 48° Tw.
6½ ,, water.
11 ℔ starch.

Boil, cool and add:—
¾ gallon acetate of chrome, 30° Tw.

The proportions here given are liable to variations according to circumstances. Indeed, no two works employ quite the same recipes, although the proportion of mordant to dye-stuff is pretty generally known and observed.

After printing, the goods are dried, steamed for one hour, and then washed and finished.

(*b*) *Application of Basic Aniline Dye-Stuffs.*—These colours all form insoluble lakes with tannic acid; hence tannic acid is the common fixing agent of the group. Arsenic in combination with alumina also gives basic-colour lakes, but their poisonous character and their inferior fastness to most reagents considerably limit their application.

The more important basic dye-stuffs are: methylene blue, methyl violet, rhodamine, auramine yellow, safranine emerald green and indoine blue. Most of them are fairly fast to soaping, but towards the action of light they vary a good deal, methylene blue being perhaps as good as any, and the malachite greens the least stable.

Their application is simple. A solution of the colouring matter is added to the requisite quantity of starch paste or gum, and, when well mixed in, the tannin is added in the form of a solution also. If desired they may be boiled up like the extract dye-stuffs (logwood, &c.), but this is not necessary unless large quantities are required, when it would be more convenient to boil the whole at once than to mix small batches by hand.

Methylene blue will serve as a type of the method by which all basic colours are compounded.

Blue. 2 gallons methylene blue, 10 per cent. solution in water and acetic acid.
6 ,, thick starch paste.
1 ,, tragacanth mucilage.
1 ,, tannic acid solution, 50 per cent.

10 gallons.

All other basic colours are made up for printing in a similar way by replacing the blue with the required dye-stuff.

After printing, goods containing basic dyes are "steamed," and passed through a solution of tartar emetic, or other salt of antimony, whereby an insoluble double tannate of antimony and colouring matter is formed, which constitutes a much faster colour than the single tannate of the dye-stuff.

Basic colours may be printed along with "mordant" and albumen colours.

(*c*) *Application of Direct Dyeing Colours.*—These colours have a natural affinity for the cotton fibre and therefore require no mordant. They are not very "fast," however, and, though used enormously in the dyeing of plain shades, they find but little employment in printing except for the tinting of printed goods, and for the "crepon" style, where the colours must be able to withstand the action of caustic soda.

They are usually printed with the addition of a slightly alkaline salt (phosphate of soda) and sulphate of soda. Amongst the hundreds of direct colours equally suitable for printing mention may be made of erica for pinks; diamine sky-blue for blues; diamine violet, and diamine, chrysamine, chloramine and dianil yellows. In fact, most of the benzidine, diamine, dianil and Congo dye-stuffs can be used for printing, but with the exception of the yellows none of them will resist the action of light and washing to anything like the extent that "mordant" and basic colours will. The general formula for printing these colours is as follows:—

4 oz. colouring matter.
¼ gallon water.
¾ ,, starch or tragacanth thickening.
4 oz. phosphate of soda.
2 oz. sulphate of soda.

After printing, with direct colours, the goods are first steamed, then slightly washed in a weak tepid soap solution and finally finished.

(*d*) *Application of Pigment Colours.*—Before the introduction of coal-tar colours, pigments and lakes played a much more important part in textile-printing than they do at present, though they are still largely used for certain styles of work. They form a series of colours more difficult to work than those already mentioned, but very fast to soap and light.

Pigment colours, being insoluble mineral precipitates or lakes, can only be fixed on the fibre mechanically; consequently they require to be applied in conjunction with vehicles which cause them to adhere to the fabric in much the same way that paint adheres to wood.

Of these vehicles, albumen is the most important and the best. It forms a smooth viscous solution with cold water, mixes readily with all the colours used in pigment printing, and possesses the property of coagulating when heated to the temperature of boiling water. When cloth printed with colours containing albumen is passed through hot steam or hot acid solutions, as in the indigo discharge style, the albumen coagulates, forming a tough insoluble colloidal deposit, which firmly fixes on the fibre any colour with which it is mixed.

The colours chiefly employed in pigment printing are: chrome yellow and orange, Guignet's green or chrome green; artificial ultramarine; lamp black for greys; the various ochres for golds and browns; zinc oxide; vermilion and its substitutes, and occasionally lakes of the natural and artificial colouring matters. All these bodies are applied in exactly the same way and may be mixed together in any proportion to form compound shades. The amount of albumen necessary to fix them varies according to the depth of shade required (between 10 and 25 per cent. of the total weight of the made-up printing colour), and although it is usually considered in text-books as a thickening agent it is rarely used as such in practice on account of its expense. As a rule the colouring matter is beaten up into a smooth paste with the necessary quantity of a strong solution of albumen and then reduced to its proper strength by the addition of tragacanth mucilage or starch paste.

The main factor in the successful working of pigment colours is their fineness of division; the finer they are the better they print and the more beautiful is their quality of colour. If they are too coarse they give rise to innumerable defects, either by sticking in the engraving or by scratching the roller, or, if they print at all, by yielding uneven masses of colour, granular and speckled in appearance and quite unsaleable. Even when finally ground they are liable to clog the engraving of the rollers—a defect which is more or less successfully overcome by replacing the colour-furnishing roller in the printing machine by a revolving brush.

The following formula of dark ultramarine blue will serve as a type of all other pigment printing colours:—

24 lb artificial ultramarine.

Place in grinding machine and beat up gradually with
4½ gallons 40 per cent. blood albumen solution.
2½ ,, tragacanth mucilage, 8 oz. per gallon.
1/32 ,, ammonia.
1/16 ,, glycerin.
1/32 ,, turpentine.
1/16 ,, olive or cotton-seed oil.

Make to 8 gallons with tragacanth or water, and grind the whole until perfectly homogeneous.

The small quantities of ammonia, turpentine, glycerin and oil are added to prevent the colour from frothing during the printing process.

Chrome yellows and oranges are frequently mixed with a little cadmium nitrate to counteract the action of sulphuretted hydrogen on the lead salts.

The great disadvantage of pigment colours is that although extremely fast to light and soap they are liable to rub off, if the fabric is subjected to much friction in washing. They also impart considerable stiffness to the goods, and for these two reasons they are therefore restricted to the printing of small patterns, or are used for such styles as window-blinds where the stiffness is not objectionable. In very pale shades they are used for printing the grounds or "blotches" of multicolour patterns, the small quantity of albumen they then contain being insufficient to appreciably affect the softness of the cloth. In several discharge styles too—notably indigo—they find extensive use, and on the whole they constitute a most useful class of colours.

(*e*) *Application of Indigo.*—Indigo is printed on cloth by several different methods, the chief of which are: (1) Schlieper and Baum's glucose process; (2) the hydrosulphite process; and (3) the production of indigo on the fibre itself by means of Kalle's indigo salt and several other artificial preparations. The first and second processes depend upon the facts that indigo in presence of caustic alkalis may be converted into indigo-white by reducing agents, and that the indigo-white, being soluble in the alkali, penetrates into the fibres of the cloth, where it is subsequently re-oxidized to its original insoluble state.

In Schlieper and Baum's process (also known as the glucose process) the cloth is first prepared in glucose, and then printed with a colour containing finely ground indigo, caustic soda and dextrine thickening (also made with caustic soda). After printing, the cloth is "aged," that is, passed through damp steam for a few minutes to effect the reduction and solution of the indigo, and is then hung up in a cool chamber for a day or two, in order to re-oxidize the indigo-white to indigo by the action of the oxygen in the air. A wash in cold water finally completes the fixation of the indigo, and the cloth may then be soaped and finished as usual. The cloth is prepared by running through a box containing a 30 per cent. solution of glucose in water; the excess is squeezed out in a mangle, and the cloth dried. It is then printed with the following colours according to shade required:—

	Dark Blue.	Medium Blue.	Light Blue.
Alkaline dextrine paste	7½ gals.	8 gals.	8 gals.
Caustic soda, 38° Tw.	1 ,,	1¼ ,,	1¾ ,,
Indigo 20 per cent. paste . . .	1½ ,,	¾ ,,	¼ ,,
	10 gals.	10 gals.	10 gals.

The printed goods should be dried quickly, and "aged" as soon as possible to prevent the absorption of carbonic acid gas from the air, after which the operations already mentioned may be proceeded with at leisure.

The well-known blue and red pattern is produced by this process, the only difference being that, instead of white cloth, turkey red dyed cloth is used, the strong alkali dissolving out, or "discharging," completely the colour from those parts of the cloth upon which it falls, and leaving the indigo as a blue pattern on a red ground.

In the *hydrosulphite process*, which is much quicker than the preceding, the reducing agent, the indigo and the alkali are all printed together on unprepared white cloth. The goods are then "aged," and allowed to lie a short time, after which they are washed-off in cold water first, until the indigo is thoroughly re-oxidized, and then in hot water or soap.

The hydrosulphite printing colour is as follows:—

$\left\{\begin{array}{l}\text{200 parts hydrosulphite N.F. (or 100 of the concentrated product).}\\ \text{450 ,, alkaline dextrine paste.}\end{array}\right.$

$\left\{\begin{array}{l}\text{150 ,, indigo 20 per cent. paste (ground up in gum).}\\ \text{200 ,, alkaline dextrine paste.}\end{array}\right.$

Thickening $\left\{\begin{array}{l}\text{150 parts dextrine or British gum.}\\ \text{850 ,, caustic soda, 70° Tw.}\end{array}\right.$

Print, dry, "age" and wash off in a copious supply of cold water

The third process with Kalle's salt is not properly speaking the printing of indigo, but of a special preparation capable of forming indigo when treated with caustic alkalis. The salt is merely dissolved and thickened with gum or starch, printed, and then passed direct through a solution of caustic soda, when the indigo is immediately developed. Instead of being passed through the alkali, which is apt to cause the colour to run before it is properly developed, the cloth is more commonly printed with thickened caustic soda, whereby the indigo is equally well produced without any fear of "running."

Besides indigo, other vat dye-stuffs, such as indanthrenes, the algol, helindone and ciba colours, thioindigo scarlet, &c., are also printed largely at the present time, yielding colours of hitherto unattained fastness to washing and to light.

(*f*) *Insoluble Azo-Colours.*—These colours do not exist as such, but require to be produced on the fibre itself from their components. They form a range of exceedingly fast colours, including orange, red, pink, maroon, brown, chocolate, blue and black, and are produced by the combination of various diazo-bodies with phenols, the most important of which latter is β-naphthol (beta-naphthol).

In practice their application is briefly as follows:—The bleached cloth is prepared in a solution of β-naphthol in caustic soda (naphtholate of soda), then gently dried and printed with the thickened diazotized amine required to produce the desired shade. The printing colour must be cooled with ice to prevent its decomposition; hence such colours are sometimes known as "ice colours."

The two colours most extensively used are para-nitraniline red and α-naphthylamine maroon, both of which are bright fast colours, only equalled by turkey red and madder chocolate for general usefulness.

On β-naphthol prepare the following colours may be obtained:—

Red with paranitraniline.
Maroon with α-naphthylamine.
Orange with orthonitrotoluidine.
Pink with azo pink 2 B.
Chocolate with benzidine.
Brown with benzidine and orthonitrotoluidine.
Blue with dianisidine.
Black with dianisidine and benzidine.

Other naphthols and other bases give a still greater variety of shades.

The naphthol prepare requires to be freshly made, and the cloth prepared with it carefully dried, if good results are to be obtained.

Paranitraniline is made up for printing by dissolving in hydrochloric acid. Nitrite of soda is then added, and, after standing a short time to complete the reaction, the resulting diazo-solution is mixed with thickening, and acetate of soda is then added to neutralize any free mineral acid still remaining, the presence of which would prevent the formation of the colour.

In practice the following formulae have given good results:—

(1) Paranitraniline Red

Prepare the bleached cloth in:—

47 parts β-naphthol.
3 ,, naphthol R.
107 ,, caustic soda, 50° Tw.
400 ,, hot water.
10 ,, tartar emetic.
12 ,, tartaric acid.

Make up to 1000 parts with hot water.

The cloth is passed through a trough containing this solution, the excess is squeezed out between two wooden rollers, and the cloth is gently dried and then printed with:—

36 parts paranitraniline C.
100 ,, ice.
100 ,, hydrochloric acid, 30° Tw.
70 ,, water.

Mix and add quickly:

24 parts nitrite of soda, 93 per cent.
70 ,, water (cold).

And just before printing add further:

100 parts acetate of soda.
100 ,, ice in large pieces.
400 ,, tragacanth mucilage, 12 per cent.

Print, dry and wash.

A similar prepare without the naphthol R. may be used for α-naphthylamine maroons, the printing colour for which is made up as follows:—

36 parts α-naphthylamine.
93 ,, hydrochloric acid, 30° Tw.
171 ,, tragacanth mucilage.

Grind till perfectly smooth in a mill and then add:

100 parts ice.
20 ,, nitrite of soda of 93 per cent. strength.
80 ,, water.
400 ,, starch and tragacanth thickening.
25 ,, benzine.
75 ,, acetate of soda.
1000

Print, dry and wash.

Immediately these diazo-colour pastes come in contact with the naphthol-prepared cloth the colour itself is formed and fixed and requires no further treatment except that of washing to remove the naphthol from the unprinted parts of the cloth.

The other bases are diazotized in precisely the same way, the quantities of acid and nitrite of soda being varied according to the molecular weights of each base.

Several processes of printing azo-colours directly, without any previous preparation of the cloth, have been proposed, but they are not in general use as yet; those which have passed the experimental stage are not very successful on the large scale, and have, for the most part, been abandoned.

(*g*) *Application of Sulphur Dyes.*—Of late years the class of colours known as "sulphur colours" have assumed a prominent place in textile-printing. They are really direct dyeing colours, but their special properties entitle them to be classed apart from those usually known under this name.

There are now an enormous number of sulphur-colours on the market under many different names, but, as they are all similar in general properties, it is needless to mention more than one series. The "thiogen colours" of Meister, Lucius and Bruning will serve as well as any to exemplify the application of these dye-stuffs in printing. They comprise yellows, golds, browns, violets, blues, greys and blacks, all fairly, and some very, fast to light and soap, and, under proper conditions, easy of application to a variety of styles.

The general recipe for printing is as under:—

30 parts by weight of colouring matter.
50 ,, ,, ,, glycerin.
80 ,, ,, ,, water.
50 ,, ,, ,, china clay beaten up with
50 ,, ,, ,, water.
40 ,, ,, ,, concentrated hydrosulphite N.F., 50 per cent. solution.
700 ,, ,, ,, alkaline British gum thickening.
1000

This paste is printed on unprepared bleached cloth, gently dried and then passed through a rapid steam ager, in from 4 to 7 minutes in dry steam at 212° F. to 220° F. (or twice for 3 minutes), after which the cloth is passed in the open width through the washing and soaping machines, and finally dried up and finished.

The sulphur colours may be used in combination with the azo-colours, on naphthol-prepared cloth, for the production of multi-colour effects, and are eminently adapted also to the production of coloured discharges on paranitraniline red and the direct-dyeing colours.

(*h*) *Aniline Black.*—Aniline black was discovered and first used by Lightfoot in 1863. It is one of the fastest blacks known, and is equally useful for direct printing by itself, and for working along with printed mordants and discharge pastes. Aniline black is formed by the oxidation of aniline.

As a rule the oxidation of the aniline is brought about by means of sodium chlorate in presence of suitable oxygen carriers such as copper sulphide, vanadium chloride or potassium ferrocyanide. Copper and vanadium blacks are usually developed after printing by being aged in a moderately warm room for a day or two, when they become converted into "emeraldine," at which stage they are taken down, and passed through a hot solution of bichromate of potash to complete the oxidation of the aniline. Great care is required in printing these two blacks, as if overdried they take fire and have occasionally caused considerable damage to buildings in consequence. The blacks made with ferrocyanide, on the contrary, may be printed in conjunction with "steam" colours, and, after a preliminary passage through a rapid steam ager, and an ammonia "gassing" box, will withstand the long steaming necessary for alizarine colours.

A copper aniline black may be made as follows:—

15 ℔ starch.
8 ℔ British gum or dextrine.
5¼ gals. water.
4 ℔ chlorate of soda.
¼ gal. olive oil.

Boil, cool and add:

8 ℔ aniline salt.
3 ℔ aniline oil.
5 ℔ sulphide of copper (precipitate pressed to a 30 per cent. paste).
1 gal. water.

This black may be either hung to develop, which is the safer course, or, if printed in fine shirting patterns, it may be "aged" through steam for 2 to 3 minutes. Whichever method is adopted the printed cloth must afterwards be passed through hot bichromate —"chroming"—and then well washed.

The following ferrocyanide black works well in practice:—

10 lb starch.
2 lb British gum.
6 lb yellow prussiate (ferrocyanide) of potash.
7 gals. water.

Boil, turn off the steam, and add:
$2\frac{3}{4}$ lb chlorate of soda in powder.

Cool and add:
$8\frac{1}{4}$ lb aniline salt.

Print, age 4 minutes through the rapid ager, chrome, wash and soap. If printed with alizarine steam colours it must be passed through ammonia vapour after "ageing," and then be steamed for one hour before chroming and washing. Sometimes the chroming is omitted, but the colour is then apt to become green after a short time owing to the action of sulphur dioxide present in the air.

Aniline black is now used almost exclusively for printing along with mordants for the madder style, and for black ground goods that were formerly dyed with logwood on an iron mordant. Shirtings and all single-colour black dress goods are also executed in aniline black, which is faster to light, washing, and perspiration than any other black except some of the sulphur blacks.

(2) *Printing of Mordants*.—This, the second of the great styles of textile printing, was, at one time, the most extensively practised of all, and is still the most important for all classes of work where the fastest colours are required. It may be conveniently divided into two branches: (*a*) the madder style, and (*b*) the printing of other mordants such as chrome, tannic acid, β-naphthol, &c.

(*a*) *The Madder Style*.—In this style the only mordants used are those of aluminium and iron.

Aluminium alone yields various shades of red and pink when dyed up in madder, or its artificial competitor alizarine. Iron alone yields with the same dye-stuffs shades varying from black to the palest lavender. Iron and aluminium mordants in combination yield colours ranging in shade from claret through all gradations of bordeaux and maroon to the deepest chocolates, according to which of the two mordants predominates in the mixture. Browns and allied colours may be dyed on the same mordants with either nitroalizarine alone, or with alizarine itself mixed with dyewood extracts—logwood, Persian berry or quercitron bark, &c.

Both aluminium and iron mordants consist of the acetates of their respective metals. The iron mordant which gives the best results is known as "black liquor." It is a crude acetate containing a good deal of organic matter which appears to regulate the speed of its oxidation and so produce much more level colours than have ever been obtained from any other iron mordant.

Aluminium acetate in the pure state is also rarely employed, the crude commercial "red liquor" being found in practice to yield the best results, both as regards colour and ease of working. The "red liquors" vary considerably in composition, some being normal acetates, others basic acetates, some normal sulphate-acetates, others basic sulphate-acetates, but their mode of application is always the same, that is, they are thickened, printed, aged and dyed in alizarine. If they are too basic they decompose on boiling, or on dilution, and become utterly useless; but this rarely happens nowadays and need not be further gone into. Many difficulties occur in the printing of mordants and their subsequent dyeing, but if the following points are observed most of them may be surmounted; (1) after printing the cloth must be gently dried, otherwise the mordants become dehydrated or "burnt," and instead of dyeing up evenly they appear patchy and very light in the overdried parts; (2) the dye-stuff must not be used in excess; and (3) the temperature of the dye-bath must be kept as low as is consistent with the fixation of the colour. If these last two points are neglected the unprinted parts of the cloth, which should remain a pure white when it is finished, will be soiled beyond repair unless indeed the "whites" are cleared at the expense of weakening the colour. Iron mordants especially are liable to unevenness due to the oxidation being too rapid; and as this defect is most noticeable in purples and lavenders, the pyrolignite of iron or "black-liquor" is frequently boiled for half an hour or more with 1 per cent. of its weight of arsenious acid, or "white arsenic," a substance which retards its oxidation. For this purpose the goods are printed with either aluminium or iron acetates, and hung or "aged" for 2 to 3 days in a brick chamber containing moist air at about 30° C. dry bulb, and 27° C. wet bulb thermometer. In this operation the "ageing" (which is really the volatilization of the acetic acid, leaving the hydrated oxide on the fibre) goes on slowly and evenly. After hanging, the last traces of acid are removed and the hydroxide thoroughly fixed by "dunging," a process in which the goods are passed through a mixture of cow-dung and chalk at a temperature of about 50° C. In this "dunging" bath they are worked altogether about $1\frac{1}{2}$ hours, at the end of which the mordants are thoroughly fixed, and all the thickening agents perfectly eliminated, thus leaving the cloth in the best condition to absorb the dye-stuff. The dyeing is carried out by working the goods at 60° C. in a mixture of alizarine, a little chalk, and glue size for 1 to $1\frac{1}{2}$ hours. They are then well washed, soaped, and the whites cleaned by a passage through weak bleaching powder solution, followed by a passage through steam. Further soaping and washing is then resorted to until the goods are quite clear and bright.

In the case of cloth dyed in red and pink alone the goods after dyeing are well washed, passed through a bath of alizarine oil containing oxalate of ammonia, and then steamed for one hour at 15 lb pressure. This brightens the colours by removing the brown appearance they possess after dyeing. When reds are associated with chocolates and purples, however, the oiling process must be carefully conducted, otherwise the two latter suffer; frequently it is omitted altogether, the brightening being effected by vigorous soaping.

By printing the following mordants a six-colour design may be produced with a single dye-stuff and in one dyeing:—

	Red.	Pink.	Chocolate.	Dark Purples.	Violet.	Black.
Aluminium acetate, 6° Tw.	12 gals.	3 gals.	$10\frac{1}{2}$ gals.	.	..	..
Black liquor, 24° Tw.	..	..	$1\frac{1}{2}$ "	1 gal.	$\frac{1}{2}$ gal.	8 gals.
Water	..	8 gals.	..	11 "	$11\frac{1}{2}$ "	4 "
British gum	..	36 lb	..	..	36 lb	..
Acetic acid	..	1 gal.	..	..	..	..
Tin crystals	$1\frac{1}{2}$ lb	$\frac{3}{4}$ lb	..	..	..	..
Cotton-seed oil	$\frac{1}{4}$ gal.	..	$\frac{1}{4}$ gal.	$\frac{1}{4}$ gal.	..	$\frac{1}{4}$ gal.
Starch	16 lb	..	16 lb	16 lb	..	16 lb

The above mordants are printed on white bleached cloth, dried, hung 2 to 3 days, "dunged," dyed, washed, well soaped and washed again; then "chemicked" through weak bleaching powder solution, and finished.

The "dunging" is performed in vats through which the cloth circulates continually during the operation. As a rule dunging is done twice, the second bath being weaker than the first. The vats or "becks" contain a mixture of:—

100 gals. water
10 lb chalk
50 lb cow-dung } 1st dunging.
at 60° C.

100 gals. water
5 lb chalk
25 lb cow-dung } 2nd dunging.

Wash well after "dunging" and dye in alizarine, &c.

The dyeing is carried out in large becks over which a roller or bowl revolves, equal in length to the beck. Over this roller the cloth is wound spirally in large loose loops so that one end of the loop is on the roller and the other dips into the dye liquor. When about 700 yds. of cloth have been entered in this way the two ends of it are knotted together, thus forming an endless rope which circulates continuously in and out of the dye-liquor. The vat or beck is then charged with alizarine, chalk and glue, the proportions varying according to the amount of space covered by the mordants on the cloth. If, for instance, half the surface is printed then the dye-liquor might be made up as follows, the quantities being calculated on the weight of the cloth:—

$4\frac{1}{2}$ per cent. alizarine (blue shade), 20 per cent.
$1\frac{1}{2}$ " acetate of lime, 28° Tw.
10 " glue solution, or size, 15 per cent. } in a sufficiency of water.

The goods are entered into this solution cold. The temperature is gradually raised to 60° C., and the dyeing continued at this for one hour or more. The goods are then washed in a similar machine, soaped well and finished off by drying.

Aniline black may be printed along with "red liquor" and iron liquor, and many other modifications also employed, but the principle of dyeing is always the same.

(*b*) *The Printing of other Mordants*.—Of these the most important are tannic acid, chrome mordants and β-naphthol.

For printing tannic acid the following is used:—

{ 5 lb tannic acid dissolved in
1 gal. acetic acid and added to
9 " starch and tragacanth paste.

The goods are simply dried after printing and the tannic acid immediately fixed by passing through a solution of—

- 2 oz. tartar emetic.
- 1 oz. chalk.
- 1 gal. water at 60° C.

After washing they may be dyed up in any of the basic aniline colours.

Various chrome mordants are employed in printing, amongst which may be mentioned chromium chromate, and chromium acetate. The former is thickened with starch or gum, printed, and fixed by being passed through boiling sodium carbonate. The latter is applied in the same way but, after printing, is steamed before the carbonate treatment. Both these mordants are suitable for dyeing with any of the dyes mentioned under the direct printing of mordant colours, such as alizarine, alizarine bordeaux, coeruleine and the natural dye-wood extracts. They are dyed similarly to the madder colours, with an addition of glue size to preserve the white of the unprinted parts of the cloth.

(3) *The Discharge Style.*—This style is now one of the most important produced. Its range is so extensive, and its modifications so numerous, that it is impossible to mention more than a few of its chief applications. It may be used for locally destroying either the colours dyed on cloth, or the mordants with which they have been previously prepared. In both cases the resulting pattern appears in white, or colours, on a full rich ground the beauty of which cannot be equalled by direct printing.

The discharging agents consist of organic acids, caustic alkalis, oxidizing agents and reducing agents, each used according to the kind of colour or mordant to be discharged.

(*a*) *Discharge of Iron and Aluminium Mordants.*—The cloth is padded with a solution of these mordants, dried in hot air, and then printed with thickened citric acid or acid citrate of soda mixed with china clay to prevent the pattern running. It is then passed through the rapid ager once or twice, "dunged," washed, and dyed in the usual way for madder colours. Wherever the discharge has been printed the mordant is dissolved out, leaving a white pattern on a dyed ground.

(*b*) Tannate of antimony mordant is similarly discharged by printing on caustic soda. The goods are passed in like manner through the ager, well washed in water, and dyed-up in any basic aniline dye.

(*c*) The chrome discharge is produced by padding the goods in chromium bisulphite; then drying them, and printing-on citric acid, or chlorate of soda and yellow prussiate of potash. They are then steamed, passed through chalk and water, well washed and dyed up in any mordant dye.

(*d*) Turkey red may be discharged in both white and coloured patterns by either oxidizing agents or caustic alkalis. (1) The dyed cloth is printed with strong citric acid, or arsenic acid, at 180° Tw., and then run through bleaching powder solution, whereby the printed parts are completely decolorized. If colours are required, the citric acid is mixed with lead salts and Prussian blue, and the fabric after passing through the bleaching powder solution, is further treated in a bath of bichromate of potash which forms with the lead salts the insoluble chrome yellow. Green is obtained by the combination of Prussian blue with the chrome yellow.

Examples:—

White. 6 lb citric acid or tartaric acid.
1 gal. water.
4 lb British gum or dextrine.
Boil together.

Yellow. 15 lb British gum.
1½ gals. dark British gum paste, 30 per cent.
2½ ,, water.
20 lb tartaric acid.
12 lb nitrate of lead.

Print, dry, discharge through bleaching powder solution, 18° Tw., and chrome.

(*e*) The dyed cloth is printed with strongly alkaline discharge pastes, passed through the "ager" two or three times, and then washed off in silicate of soda. If blue, yellow and green discharges are desired the dyed cloth must first be passed through glucose solution, well dried, printed with the colours, "aged," passed through silicate of soda, chromed in bichromate, well washed and dried. Examples:—

White. 10 lb stannous chloride dissolved cold in
8 gals. alkaline thickening.
2 ,, silicate of soda, 70° Tw.

Blue. 15 lb indigo pure 20 per cent. paste.
1/32 gal. turpentine.
1/16 ,, glycerin.
1½ ,, British gum paste.
7 ,, alkaline thickening.

Green. 8 parts of the yellow without silicate.
1 part of blue.

Yellow. 30 lb lead hydrated 50 per cent.
2 gals. water.
¾ ,, silicate soda.
5¼ ,, alk. thickening.

Alkaline Thickening.

15 lb yellow dextrine.
8 gals. caustic soda, 100° Tw.

(*f*) *Paranitraniline red* is discharged by means of the new hydrosulphite-formaldehyde compounds. The dyed cloth is printed with the following:—

25 lb hydrosulphite N.F. conc., or hydraldite conc.
1½ gals. British gum paste.
Heat till dissolved and add—
1/32 gal. glycerin.
4½ ,, starch-tragacanth thickening.

After printing, age twice for 4 minutes through dry steam at 220° F., then wash well and soap.

Coloured discharges are obtained by mixing hydrosulphite, tannic acid, aniline or phenol, and basic colouring matters together. Mordant dyes fixed with chromium acetate may also be used.

On α-naphthylamine maroon the above discharge white requires the addition of induline scarlet, patent blue or anthraquinone, before it becomes effective, otherwise the procedure is the same as for paranitraniline red.

(*g*) Indigo is usually discharged by oxidation. For this purpose the dyed cloth is printed in two different ways. Firstly, with chlorate of soda, and red or yellow prussiate of potash together with a little citric acid or citrate of soda; secondly, with chromate of potash. In the first instance, the cloth is "aged" through the rapid ager after printing, and, in the second, is passed through a vat containing hot sulphuric acid and oxalic acid. Coloured discharges may be obtained in both methods by adding albumen and pigment colours to the discharging agents.

(1) Discharge by steaming:—

12 lb citric acid, dissolve in:
7 lb caustic soda, 70° Tw., and add:
12 lb sodium chlorate.
5 gals. British gum paste.
Heat till dissolved, cool and add:—
1¾ gals. British gum paste.
2 lb yellow prussiate of potash.
Print, steam and wash.

Chlorate of aluminium is also used for this process, but it acts very energetically and is apt to tender the cloth.

(2) Chromate discharge:—

White. 8½ gals. British gum paste.
12 lb bichromate of soda.
½ gal. turpentine.

Yellow. 32 lb chrome yellow pigment.
3 gals. 50 per cent. albumen solution.
½ ,, thick tragacanth mucilage.
¼ ,, oil (vegetable).
12 lb bichromate of soda neutralized with
¾ gal. caustic soda, 70° Tw.
½ ,, water.

Print, dry, pass through a "beck" (*i.e.* a bath) containing:—
100 gals. water.
50 lb sulphuric acid (168° Tw.).
50 lb oxalic acid.
Then well wash and dry.

With these oxidation discharges it is impossible to prevent the fibre being attacked in the discharged portions, with the result that it is partially converted into oxycellulose. Recently a method has been brought out for the production of a white discharge on indigo which is said to do away with the formation of oxycellulose and which consists in printing on a thickened solution of sodium nitrate and, after drying, running through sulphuric acid of 50° Tw.

Another method of producing white discharges on indigo consists in printing the dyed cloth with hydrosulphite N.F., then steaming and running through a boiling solution of caustic soda. Good whites are thus obtained without the formation of oxycellulose, but the process is expensive.

(*h*) *Direct dyeing* or *substantive colours* can be easily discharged with the hydrosulphite discharge used for paranitraniline red (see above). It must be reduced in strength to about one-fourth for dark shades, and much weaker for lighter colours. Direct colours were formerly discharged by stannous chloride or acetate, but the hydrosulphite has almost entirely displaced these salts for white discharges.

(*i*) Discharges on manganese bronze are of little importance at the present time. They are effected by means of stannous chloride, colours being obtained by the addition of basic dyes and dyewood extracts.

(*j*) Sulphur-colours, dyed basic colours, and some alizarine colours, are discharged with chlorate and prussiate like indigo.

(4) *The Resist or Reserve Style.*—Reserves are substances which, when printed, prevent the fixation or development of mordants and colours subsequently applied, and are used to produce effects similar to those obtained by discharge printing.

The principal reserves are those used for madder dyed goods, steam alizarine reds and pinks, steam basic colours, vat indigo blue, insoluble azo colours, sulphur-colours and aniline black.

(*a*) *Reserves under Aluminium and Iron Mordants.*—For the production of this important class of goods, use is made of the fact that alkaline citrates prevent the fixation of the mordants. The cloth is first printed with citrate of soda (or sometimes citric and tartaric acids for iron mordants), then dried, and again printed over the previous impression, with either a fine "all over" pattern or flat uniform ground, in iron or aluminium mordants. The fabric is then aged, "dunged," washed and dyed as already described, with the result that wherever the "reserve" of citrate or acid was printed a white pattern is left on a figured or plain ground. The fine patterns printed over "reserves" are called "covers" and the plain grounds "pads," hence the name "cover and pad" style in cases where, as frequently happens, a dark "cover" and a light "pad" are both printed over a white "reserve." The "cover and pad" style is, for the most part, restricted to dyed alizarine purples under which red, black, dark purple and white can all be reserved at the same time, thus giving rise to very pleasing effects. For example: white cloth is first printed with four "colours," viz., citrate of soda and citric acid for the white; logwood and iron for the black; strong iron mordant for the purple; and aluminium acetate at 6° Tw. with 8 oz. per gallon of stannous chloride for the red. (The stannous chloride acts as a resist for iron mordants.) The whole is then "covered" in a fine pattern printed in a fairly strong iron mordant, dried, and again printed, in a very weak iron mordant, with a pad roller, that is, a roller which prints a uniform ground over the whole surface of the cloth. After this last printing, the cloth is "aged" for a day or two, by being hung as previously described, then "dunged," washed and dyed in a blue shade of alizarine. When finally washed, soaped and "cleared" in bleaching powder solution the first printed pattern in white, red, black and purple is seen to stand out, clearly and sharply, from a figured background in two lighter shades of purple. This "cover and pad" style of reserve printing constitutes one of the staple processes of nearly all print-works, and is produced in enormous quantities for both home and foreign markets. Red is not often introduced as in the above example, the usual colours being white, black and two purples. The same method of working can be adopted with aluminium mordants for red and pink covers and pads, but they are better produced with the steam alizarine colours as below.

(*b*) *Reserves under Steam Alizarine Red and Pink.*—In this case a reserve composed of citrate of chromium alone, or in conjunction with citrate of soda, gives the best results. The goods are first prepared in alizarine oil and then printed with the following:—

10 lb china clay.
½ gal. citrate of soda, 54° Tw.
½ ,, citrate of chromium, 42° Tw.
½ ,, water.
2½ ,, British gum paste.

After printing the above, the goods are dried and again printed either with "cover" or "pad" or both, in alizarine pink, dried, steamed for 1½ hrs., well washed and soaped. On leaving the steamer the parts printed with the resist are yellow, but become quite white on soaping. Like the purples, the alizarine pinks can be reserved in colours. For blue, green, yellow and violet the ordinary steam basic colours are used with additions of citric or tartaric acid.

Example:—

7 lb china clay.
½ gal. water.
6¼ ,, British gum paste.
2 lb methylene blue.
1 lb citric acid.
1 gal. acetic acid.

Boil, cool, and add:—

1¼ gals. 50 per cent. tannic acid solution in acetic acid.

Red with steam alizarine red; yellow with thioflavine in place of methylene blue in above; green a mixture of blue and yellow. These colours with the white reserve may all be printed at once. Then steam as usual, pass through a solution of tartar emetic and chalk, wash well and soap.

(*c*) *Reserves under Insoluble Azo-Colours.*—These are based upon the action of stannous chloride, which prevents the combination between the β-naphthol and the diazo bodies by reducing the latter to hydrazines. The β-naphthol prepared cloth is printed with the following colours, then dried and passed through diazotized solutions of paranitraniline for red grounds; a-naphthylamine for maroon; ortho-nitrotoluidine for orange, &c., &c. The cloth is then washed and soaped until the "whites" are clean.

White Resist. 5 gals. gum senegal solution.
30 lb tin crystals.
5 lb tartaric acid.

For heavy rollers this may be reduced with more gum.

	Blue.	Yellow.	Green.	Pink.
New methylene blue N.	2 ½lb	..	..	..
Auramine G. (B.A.S.F.)	..	..	2 lb	..

Tannic acid sol., 50 per cent.	1½ ,,	2 ,,	1½ ,,	2 ,,
Tin crystals	20 lb	20 lb	20 lb	20 lb
Make up to	10 gals.	10 gals.	10 gals.	10 gals.

Potassium sulphite is also used as a white reserve under insoluble azo-colours with good results.

(*d*) *Reserves under Steam Basic Colours.*—The white cloth is printed with:—

20 lb china clay.
2½ gals. water.
15 lb British gum.
20 lb sodium tartar emetic.
20 lb zinc sulphate.

All boiled well together,

and then covered, or over-printed, with any steam basic colour—steamed one hour, passed through tartar emetic, then washed and soaped, when the reserve white above comes away, bringing along with it the colour printed upon it and leaving a white pattern on a printed ground.

(*e*) *Reserves under Vat Indigo Blue.*—This was formerly a very important style, but at present is only used in special cases. Resist or reserve effects are obtained by printing the white cloth with oxidizing agents, &c., and subsequently dyeing it in the indigo vat. In addition to oxidizing agents the reserve pastes contain lead sulphate, barium sulphate, resins, fats and thickenings in various proportions. The following is a good white reserve:—

15 lb flour.
6 gals. water.

Boil, cool a little, and add—

18 lb copper sulphate powdered.
2½ lb copper nitrate, 90° Tw.
1 pint alizarine oil.

Yellow. 2¾ gals. British gum paste.
33 lb lead sulphate, 66 per cent. paste.
18 lb zinc sulphate.
22 lb lead nitrate.

Print the white and yellow, dry, dye in the indigo vat—sour slightly in sulphuric acid, wash, and pass into a hot solution of bichromate of soda, which develops the lead yellow. Reserve whites also contain lead salts when used for white alone, but obviously the white given is best suited to white and yellow reserves, as its soluble copper salts wash out before the "chroming" stage is reached.

(*f*) *Reserves under Sulphur Colours.*—These are obtained with zinc chloride. They are not much used, but are capable of yielding fine effects.

(*g*) *Reserves under Aniline Black.*—Reserves under aniline black are produced with caustic alkalis, alkaline carbonates, silicates and sulphites, sulphocyanides, oxide of zinc and the acetates of magnesia, zinc and soda. The white and coloured resists may be printed upon either the undeveloped black or upon the cloth before the black is applied.

In the former case the cloth is slop-padded through a mangle-box with the following black:—

7½ lb aniline hydrochloride.
3½ lb sodium chlorate.
4 lb potassium ferrocyanide.
10 gals. water.

It is then very carefully dried in hot air so that it becomes no darker than a pale yellow; if it is green before printing, the white is sure to be bad.

The dried padded cloth is then printed with the "resist" colours, dried and steamed 3 to 4 minutes in a rapid ager, chromed through warm bichromate of potash, and finally washed and soaped. During the steaming the black is developed all over the cloth except where the colours are printed. Here its development is prevented by the alkali or the reducing agent, whichever may be present, in the colour, and instead of a plain black dyed piece a coloured design on a black ground is produced. The following formulae may be employed for white and coloured resists:—

White. 8 lb starch.
8 lb British gum.
30 lb potassium sulphite, 90° Tw.
3 gals. water.
15 lb soda acetate.
10 lb bisulphite of soda, 66° Tw.
¼ lb ultramarine blue.

Boil together.

	Red.	Pink.	Blue.	Yellow.	Green.	Violet.
Rhodamine 6 G. (100 per cent.)	2¼ lb	1 lb	..	..	..	..
Auramine O	¼ ,,	..	..	..	..	..
Acridine yell. G.	..	..	..	2 lb	2¼ lb	..
Thionine blue O.	..	..	2 lb	..	..	..
New solid green 2 B.	..	..	..	..	1 lb	..
Methyl violet, B. x.	..	..	..	..	..	2 lb
Water	1¾ gals.	1¾ gals.	1½ gals.	1½ gals.	1½ gals.	1½ gals.
Tragacanth mucilage	1 ,,	1 ,,	1 ,,	1 ,,	1 ,,	1 ,,
Glycerin	..	..	¼ ,,	¼ ,,	¼ ,,	¼ ,,
Albumen, 40 per cent. solution	1 gal.	1 gal.	1 ,,	1 ,,	1 ,,	1 ,,
Resist paste	6 ,,	6 ,,	6 ,,	6 ,,	6 ,,	6 ,,

Print on the padded cloth, age, chrome and wash. The resist paste is as under:—

Resist Paste. 10 lb zinc oxide.
1½ gals. magnesium acetate, 40° Tw.
2½ ,, tragacanth mucilage (dragon).
1 ,, starch paste.

For reducing the colours take 6 parts resist paste.
4 ,, starch paste.
4 ,, white resist.

Very good results can be obtained by the alternative method, *i.e.* printing the resists on white cloth and applying the black afterwards. The basic colours are chiefly used, though chrome yellow and ultramarine are also employed for some styles. The following formulae will serve as types of the composition of white and colours:—

White. 20 lb precipitated chalk.
5 lb potassium sulphite, 90° Tw.
5 lb acetate of soda.
½ lb ultramarine blue for sightening.
1 gal. water.
6 ,, starch paste.

The whole ground together in a mill.

Colour. 2 lb basic dye-stuff.
1 gal. water.
2¼ ,, starch paste.

17 lb zinc oxide.
1 gal. water.
¼ ,, glycerin.
¼ ,, turpentine.
¼ ,, bisulphite of soda.
3 ,, starch paste.

Print on white cloth, allow to lie a day or two, then slop-pad in the Prud'homme black already given, dry, age, chrome and soap.

Pigment colours may be applied on black padded cloth as follows:—

Yellow. 40 lb chrome yellow, &c. &c.
2½ gals. 40 per cent. albumen.
2½ ,, tragacanth water, 6 oz. per gal.
6 lb soda ash.
1 gal. citrate of soda, 40° Tw.

Other methods, varying in detail, have been used from time to time, but the above two are at the present time generally employed—especially the former, by which many fine patterns have been produced in all sorts of delicate and artistic shades.

The Treatment of Cloth after Printing.

After printing, the various classes of goods undergo many different treatments according to the character of the colours printed. These treatments include steaming, hanging in the ageing chamber, passing through tartar emetic, the chalk bath, washing, soaping, "chemicking" or clearing and finishing.

(1) The operation of steaming is necessary for all styles except those with the insoluble azo-colours, vat dyes discharged, and some colours that are precipitated on the fibre. The short steaming necessary for most discharges, indigo blue prints, and aniline black is effected in the Mather and Platt ager, of which a sketch is here given (fig. 2) showing its principle.

It consists of an iron box A A A through which the goods (indicated by the dotted line) pass in the direction of the arrows. They enter at B, and traverse the whole chamber over a series of top and bottom rollers C C C, finally emerging at the same point B, whence they are drawn forward, by mechanical means, and plaited down on a waggon placed conveniently near. Steam enters the chamber A A A by the steam pipe D at the bottom, and escapes through the same slot (B) that the cloth enters and leaves by. An engine or electric motor drives the gearing, and the whole process is continuous.

This ager affords quite a sufficient steaming for aniline blacks, printed indigo, chlorate discharges, and for some mordants, but alizarine reds and pinks, mordant dyes generally, and basic colours require much more than the 2 to 3 minutes' exposure to steam which is all that can be given in the ordinary Mather-Platt ager, although they are frequently passed through it to eliminate the greater part of the volatile acids they contain. Paranitraniline red discharged with hydrosulphite also requires a modification of the ager for its success—for the steam must be very hot and very dry if any of the azo-colours are to be effectively discharged by the hydrosulphite method.

A longer exposure to the action of steam is obtained by means of the *cottage steamer* and the *continuous steamer*, in both of which goods may be steamed for any length of time. The cottage steamer consists (1) of a cylindrical iron box or chamber fitted with a false bottom on which rails are laid, and under which lie the pipes for the admission of steam, and for the drawing off of the condensed water; and (2) of a carriage or iron framework mounted on wheels and furnished with a series of removable rods capable of being revolved by means of spur-wheel gearing. Convenient lengths of the cloth to be steamed, together with a "back grey" (a piece of unbleached calico) are then wound in the open width, into a sort of broad hank on a folding frame. As each hank, so to speak, is completed it is removed from the winding frame and hung over one of the rods, which is then placed in position on the carriage.

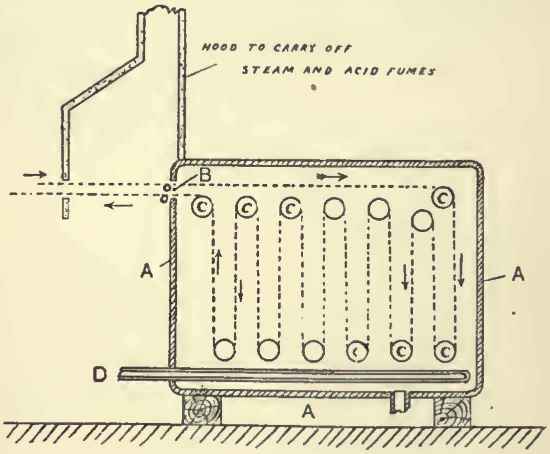

FIG. 2.

When the latter is fully loaded in this way it is run into the "cottage," the doors are closed, and steam turned in. The steaming is continued for various periods of time—from ¾ hour to 2 hours—according to the style of work in hand, and either with or without pressure, as may be required. The carriage is then withdrawn and the goods unwound in readiness for subsequent operations.

The object of enveloping the printed goods in a "back grey" is to prevent the colour from marking off from the face of one fold on to the back of the next, and also to minimize the risk of damage from drops of condensed water. This latter defect is further guarded against by heating up for an hour or so every morning before any goods are introduced.

In works where the modern continuous steaming apparatus is installed the cottage steamer is reserved for the treatment of dyed alizarine reds and for goods, such as heavy printed velvets, which are difficult to manipulate in the continuous steamer.

The continuous steamer was originally invented by Cordillot, but its present efficient form is due to Messrs Mather and Platt, who have continually improved it, so that now it bears but little resemblance to Cordillot's original machine. Its construction is too complex to be adequately described without the aid of detailed sketches. Generally speaking, it may be said to consist of a long, high, narrow chamber of brick, through which the cloth passes continuously in the form of long loops suspended from rods resting upon, and carried forward by travelling chains, situated at the top, and close to the sides, of the chamber. Steam is admitted to this chamber through a series of pipes at the bottom, and the cloth enters and emerges through slots at the top of its opposite ends. On entering, the cloth falls over one of the slowly travelling rods and continues to run downwards until a sufficient length to form the loop has run in. By this time the first rod has moved forward and a second taken its place, with the result that the cloth now falls over the second rod and commences to form the second loop. At this point—the commencement of a second loop—the second rod comes in contact with a brass bar carried by arms pivotted above. The object of this bar, which clips the continuously entering cloth firmly between itself and the rod until the second loop is complete, is twofold, namely (1) to prevent too much cloth being fed into the first loop, and (2) to prevent the weight of the first loop from pulling the cloth over the second rod during the formation of the second loop. By the time this latter is complete the second rod has moved sufficiently far forward to escape contact with the pivotted brass bar, which thereupon swings back and takes up a similar position on the third rod. In this way each rod is supplied with cloth, which it carries forward continuously until the other end of the steamer is reached, where both cloth and rods emerge—the former through the top of the chamber and the latter through a slotted opening at the top of the end wall. Through a similar slot, at the beginning end of the steamer, the rods are fed in automatically as long as any cloth remains to be steamed.

The usual time occupied in passing the goods through a "steamer" of this description is one hour, but it may be shortened or prolonged at will, and, if desirable, the goods may be allowed to remain in it for any length of time.

The room used for *ageing* is lofty and is furnished near the top with suspending rods of wood, and at the bottom with a series of steam inlet pipes through which thin streams of free steam may be introduced into the chamber, as required. Its temperature is generally kept about 36° C. on the dry-bulb thermometer and 32°–33° on the wet-bulb thermometer.

"*Dunging*" is carried out in a series of becks provided with rollers at the top and bottom, and heated by steam pipes. It may also be performed in becks through which the cloth passes in rope form. Many attempts have been made from time to time to replace cow-dung by sodium silicate, phosphate, arsenite and carbonate of ammonia, but none of them yield results quite so good as cow-dung.

The tartar emetic treatment is only used for the fixation of tannin mordants, and of basic aniline colours printed with tannic acid. It is performed by passing the cloth in the open width over and under a series of wooden rollers arranged in a water-tight box—a beck—containing the following solution:—

2 ℔ tartar emetic.
2 ℔ chalk.
16 gals. water at 60°–70° C.

The chalk is added simply to neutralize the acid salt produced in the bath—a salt which exerts a solvent action on the basic colour tannin lakes and utterly spoils any ultramarine blues that may have been printed in combination with them.

Chroming is only applied to a few styles, such as aniline black, catechu brown, and colours containing salts of lead which have to be converted into chrome yellow. "Chroming" is carried out in a beck similar to that used for tartar emetic. The cloth runs continuously through a 3 to 4 per cent. solution of bichromate of potash at 60° C.; the excess is squeezed out in a mangle, and the cloth then passes directly into a washing machine to clear it completely of the chrome. When alizarine reds, and other colours susceptible to chrome, are present, the chroming must be either omitted altogether or the operation conducted cold with a very weak solution.

Washing is a very important process, and upon its proper performance depends a good deal of the final success of the work. It may be carried out in several different ways according to the different styles of work to be treated. Alizarine reds and pink, both printed and dyed, dyed chocolates, purples, &c., aniline black, indigo blue, &c. &c., all very fast colours, are usually washed and soaped in the rope form in machines like that described for madder-dyeing. Other colours, especially pigments, must be washed, in the open width, through a series of wash-boxes furnished with rollers over which the cloth passes. In these boxes the water usually enters where the cloth leaves, thus ensuring that the cleanest cloth gets the cleanest water. Some of the boxes are occasionally fitted with heaters and others again with "spirt pipes" through which the water is forced at a high pressure for the purpose of causing it to pass straight through the cloth. Other types of machine are also used, for details of which some technical work must be consulted.

Soaping is also an important factor in the production of the best work. It clears the white parts of the goods, brightens the colours and generally improves the whole appearance of the cloth. The strength and temperature of the soap solution, the duration of the soaping and the type of machine used are all varied according to the fastness of the colours to be soaped. As in washing, the alizarine dyed colours, alizarine "steam" reds and pinks, aniline black and the ice-colours, will not only withstand a long, hot and strong soaping, but are greatly brightened and enhanced in beauty thereby. On the other hand, direct dyeing colours, basic colours, pigments and a few others require only a moderate soaping and that in the open width. Colours which will stand a drastic soaping are usually soaped, in spiral becks, in the rope state, and pass from one to another of these becks, going through as many as half a dozen times before being washed off in water. Goods requiring to be soaped in the open width are treated in a special soaping machine known as the "open soaper." In principle this is simply a range of watertight boxes each fitted with rollers at the top and bottom. The first two or three boxes contain hot soap solution and the rest hot or cold water or a series of "spirt pipes" to better wash out the soap. Very frequently open soapers are supplied with "tartar emetic" and "chroming" boxes, so that the goods can go through two or more processes directly and without any intermediate handling.

"*Chemicking.*"—In this process all traces of colour still remaining after soaping are removed from the white parts of the printed cloth, by a weak solution of bleaching powder. Two methods are used in applying the "chemick," or bleaching powder solution, to the cloth. In the first the cloth is passed between a pair of squeezing bowls the lower of which is of wood, and revolves partly immersed in a solution of bleaching powder or "chemick" varying in strength from ⅛° Tw. to ½° Tw. This lower bowl carries the chemick to the cloth, the excess is then squeezed by passing between the two, and the cloth goes forward over a set of steam-heated drying cylinders, during its passage over which the bleaching properties of the chemick effectually remove the last traces of colour on the white parts of the cloth and leave it perfectly clean and bright.

The second method of "chemicking" is employed when the cloth is too deeply stained to be successfully "cleared" by the first. All madder-dyed goods, and goods printed in strong heavy dark-coloured patterns, are liable to attract, to their white parts, a considerable amount of colour during the dyeing, washing and soaping operations. They therefore require a stronger "chemicking" to clear them, and this the second method supplies. The goods are passed successively through (1) a trough containing "chemick" at about ¼° Tw.; (2) a pair of squeezing rollers; (3) a small steam chest fitted with half a dozen guide rollers top and bottom, and a steam admission pipe; (4) a series of "spirt pipes" to wash out the bulk of the lime salts; and (5) through a washing-box and squeezing rollers, whence they go directly to a drying machine.

In both methods the strength of the "chemick" depends upon the power of the resistance to its action of the colours printed, and great care must therefore be taken to keep it weak enough.

Occasionally a little ultramarine blue is added to the chemick for the purpose of correcting the yellowish tinge usually possessed by bleached cotton.

From the fact that two or more styles can be combined in one pattern it is obviously impossible to formulate any general rule for the practical application of any of the foregoing after treatments.

For example, in aniline black resists the black ground will stand any amount of soaping, but the basic colours which constitute the pattern are only moderately fast to soaping, and, consequently, this process must be so regulated as to yield the best possible results. The same may be said of alizarine reds and pinks printed in combination with basic or pigment colours, and of paranitraniline red and other ice-colours associated with basic colours.

Finishing.—In this process the cloth undergoes various operations of softening, stiffening, embossing and polishing or smoothing, according to the requirements of the customer. The following substances are chiefly employed for the above purposes:—

Softening Agents.—Turkey red oil, tallow, paraffin, stearine, wax and certain soaps.

Stiffening Agents.—Starch of all sorts, dextrine, gum tragacanth, vegetable gelatine or Blandola, glue size, various preparations of soluble starch, lichens, &c. &c., all of which are applied on special finishing mangles, and either to one or both sides of the cloth.

Hygroscopic substances, such as zinc chloride, glycerin and glucose are added to the stiffening pastes for the purpose of softening the feel of the cloth without detracting from its "body."

The smoothing, polishing and embossing of the fabric are all performed on various types of calenders. Smoothing and polishing calenders have highly polished steel "bowls" which may be heated by steam or gas, embossing calenders have an engraved steel or brass bowl working against one of compressed paper, or one in which depressions are engraved to exactly correspond with the projections on its fellow. The cloth is run between these various kinds of bowls according to the effect desired. In the finishing process all creases are smoothed out of the cloth, and it is stretched to its proper width (and its weft straightened if awry) on special

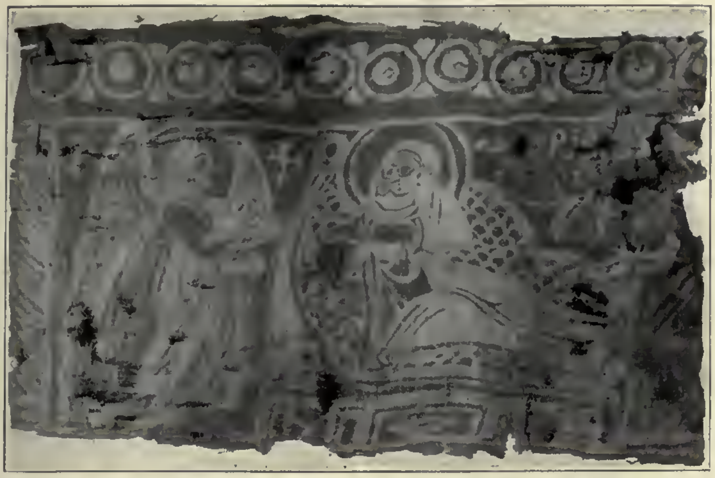

FIG. 1.—Linen, dyed blue, the "reserved" parts represent the Annunciation; above the reclining figure of the Virgin Mary is the word ΜΑΡΙΑ. Coptic, probably 5th or 6th century. 18 in. × 2 ft. 5 in.

FIG. 2.—Child's Tunic of linen dyed blue, the pattern being "reserved." Coptic, 4th century (?). 18¼ in. × 23½ in.

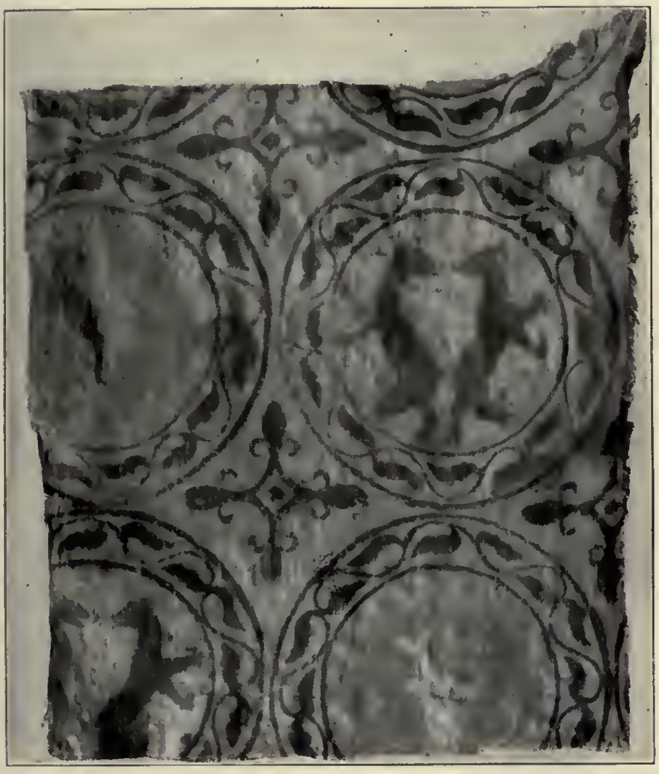

FIG. 3.—Piece of red silk, printed in red, green, and black from wood blocks, with a repeating pattern of black circles or roundels containing pairs of animals and dragons; floriated crosses in the interspaces. Rhenish, 12th or 13th century. 15⅞ in. × 12⅝ in.

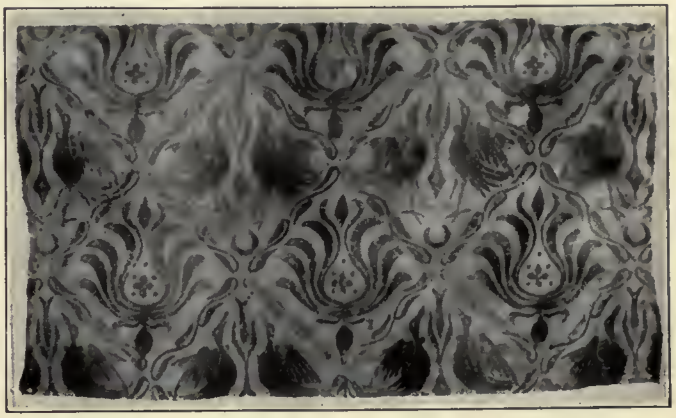

FIG. 4.—Piece of red silk, printed in black from wood blocks, with a trellis pattern enclosing pairs of birds and anthemions. Rhenish, 13th or 14th century. 8⅜ in. × 13¾ in.

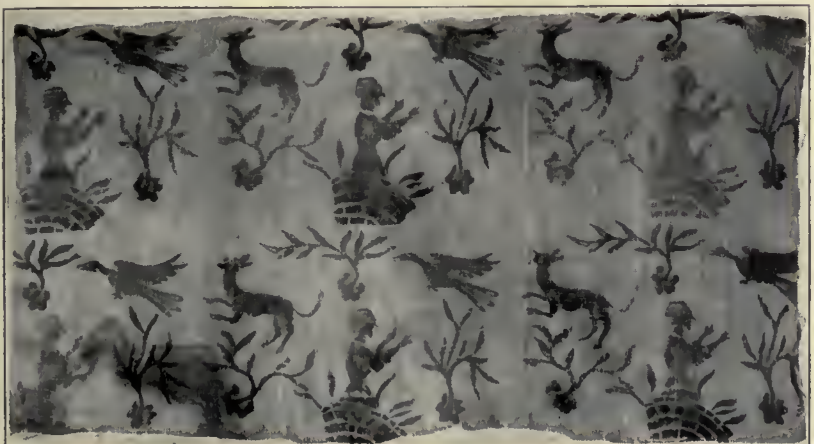

FIG. 5.—Piece of linen, printed in black from a wood block, with a pattern composed of repetitions of a lady on a turret, leafy sprays, a hound, and a bird on the wing. Rhenish, 14th century. 9½ in. × 19¾ in.

FIG. 6.—Strip of linen printed in deep purple from a wood block, with a repeating pattern of eagles and conventional leaf and fruit forms. Rhenish, 14th or early 15th century. 20¼ in. × 6½ in.

TEXTILE PRINTING

FIG. 7.—Portion of reddish linen lining for a chasuble printed in black from wood blocks, with a repeating pattern composed of five-lobed shapes enclosing conventional fruit device surrounded by small blossom and leaf forms. Rhenish, 15th century; from the neighbourhood of Düsseldorf. 3 ft. 8 in. × 24½ in.

FIG. 8.—Cotton print in colours. Dutch, 17th century. About 14 in. × 9 in.

FIG. 9.—Part of a coverlet of cotton, printed at Genoa, in colours, from metal plates engraved with trees, flowers, birds, and animals in the style of Indian palampores or printed calicoes. 19th century. About 6 ft. × 3 ft.

FIG. 10.—Part of a hanging of cotton, printed in red from metal plates engraved with repetitions of pictorial scenes. At the bottom is printed "D 5 T. P. Meillier & Ce de Beautiran près Bordeaux Bon Teint. MF. 3 X. Comm. 19." French, second half of 18th century. 4 ft. 6 in. × 3 ft. 4 in.

FIG. 11.—Part of a cotton chair back, printed in red from a metal plate engraved with a Chinese pagoda in a landscape; in front is a woman kneeling on the ground, while a priest stands to the left holding up an image. Marked "Collins Woolmers." English, dated 1766. 24 in. × 24¼ in.

FIG. 12.—Linen panel, with a stipple engraving printed in colours, for use as a small fire-screen. English, late 18th century. 2 ft. 4½ in. × 2 ft. 3½ in.

"stentering" machines. On these machines the damped cloth is carried forward, over steam-heated drying plates, by two travelling endless chains, each link of which is constructed to clip the selvedge of the cloth. The distance apart of these chains can be regulated to suit various widths of cloth and in travelling forward they diverge, so that as the cloth advances it gradually becomes stretched out to the required width and is dried at the same time to prevent it contracting when it is released from the pull of the chains, as it leaves the machine.

Finally the goods are cut into certain lengths, wound round flat boards, tied up, ticketed and packed.

Wool-Printing.

The printing of wool differs little from the printing of cotton in general. Most of the colours employed in the one industry are used in the other, and the operations of steaming, washing and soaping are almost identical.

Unlike cotton, however, wool requires to be specially prepared, after bleaching, if the full tinctorial value of the colours is to be obtained.

Two quite different methods of preparation are resorted to, namely (1) the chlorination of the wool; and (2) the precipitation of stannic acid on the fibre. In the first method the woollen fabric is first passed through a solution of bleaching powder, then well squeezed and passed, without washing, into dilute sulphuric or hydrochloric acid, squeezed again and well washed in water, after which it is dried. Great care and experience are demanded in this operation to prevent the wool from becoming hard and yellow.

In the second method the cloth is padded in stannate of soda, well squeezed, passed into dilute sulphuric acid, well washed and dried. For certain styles of work it is necessary to combine both preparations.

Although alizarine, mordant colours and dyewood extracts can be used on wool, the vast majority of patterns printed on wool are executed by means of acid dye-stuffs and basic colours, for both of which this fibre possesses a natural affinity. In most cases therefore these colours are simply dissolved in a little acetic and citric acids, thickened with gum and printed without any further addition. The addition of tannic acid, however, can be made to, and considerably increases the fastness of, the basic dyes. Mordant colours like logwood black are applied in the usual way.

The printing of wool is carried out exactly as for cotton, but if the best results are to be obtained, the engraving of the rollers must be deep, the blanket on the machine as soft as possible, and the drying of the printed cloth very gentle. After printing, the goods are steamed in moist steam or wrapped between moistened "greys" and steamed in a "cottage" steamer. If too little moisture is given, the colours lack both strength and brilliancy; if too much they run. The correct degree of dampness can only be determined by experience of the work, combined with a special knowledge of the particular apparatus employed.

After steaming, the printed goods are washed in plenty of water, then dried up and finished with a little glycerin or some waxy preparation.

Discharges may be very easily obtained on wool dyed in acid dye-stuffs, by means of stannous chloride and basic colours for the coloured effect, and hydrosulphite for the white.

Silk-Printing.

Silk-printing calls for no special mention. The colours and methods employed are the same as for wool, except that in the case of silk no preparation of the material is required before printing and the ordinary dry "steaming" is preferable to damp "steaming."

Both acid and basic dyes play an important rôle in silk-printing, which for the most part is confined to the production of articles for wearing apparel—dress goods, handkerchiefs, scarves, &c. &c.—articles for which bright colours are in demand. Alizarine and other mordant colours are mainly used, or ought to be, for any goods that have to resist repeated washings and prolonged exposure to light. In this case the silk frequently requires to be prepared in alizarine oil, after which it is treated in all respects like cotton—steamed, washed and soaped—the colours used being the same.

Silk is especially adapted to discharge and reserve effects. Most of the acid dyes can be discharged in the same way as when they are dyed on wool; and reserved effects are produced by printing mechanical resists, such as waxes and fats, on the cloth and then dyeing it up in *cold* dye-liquor. The great affinity of the silk fibre for basic and acid dye-stuffs enables it to extract colouring matter from cold solutions, and permanently combine with it to form an insoluble lake. After dyeing, the reserve prints are washed, first in cold water to get rid of any colour not fixed on the fibre, and then in hot water or benzene, &c., to dissolve out the resisting bodies.

As a rule, after steaming, silk goods are only washed in hot water, but, of course, those printed entirely in mordant dyes will stand soaping, and indeed require it to brighten the colours and soften the material. (E. K.)

II. Art and Archaeology

Printing patterns on textiles whether of flax, cotton or silk, by means of incised wooden blocks, is so closely related in its ornamental effects to other different methods of similar intention, such as by painting and by processes of dyeing and weaving, that it is almost impossible to determine from the picturesque indications afforded by ancient records and writings of pre-Christian, classical or even medieval times, how far, if at all, allusion is being made in them to this particular process. Hence its original invention must probably remain a matter of inference only. As a process, the employment of which has been immensely developed and modified in Europe during the last hundred years by machinery and the adoption of stereotypes and engraved metal plates, it is doubtless traceable to a primeval use of blocks of stone, wood, &c., so cut or carved as to make impressions on surfaces of any material; and where the existence of these can be traced in ancient civilizations, *e.g.* of the Chinese, Egyptians and Assyrians, there is a probability that printing ornament upon textiles may have been practised at a very early period.[1] Nevertheless, highly skilled as the Chinese are, and for ages have been, in ornamental weaving and other branches of textile art, there seem to be no direct evidences of their having resorted so extensively to printing for the decoration of textiles as peoples in the East Indies, those, for instance, of the Punjab and Bombay, from whose posterity 16th-century European and especially Dutch merchants bought goods for Occidental trade in "Indiennes" or printed and painted calicoes.

Whilst the earlier history of stamping patterns by hand on to textiles in the East has still to be written, a serious attempt has recently been made to account for the existence of this decorative process in Europe during several centuries prior to the introduction of the "Indiennes" above mentioned. As in the case of weaving and embroideries, specimens of printed stuffs have of recent years been obtained from disused cemeteries in Upper Egypt (Akhmîm and elsewhere) and tell us of Egypto-Roman use of such things. Some few of them are now lodged in European museums. For indications that earlier Egyptians, Greeks and Romans were likely to have been acquainted with the process, one has to rely upon less certain evidence. Of textiles painted by Egyptians there are many actual examples. Apart from these there are wall paintings, *e.g.*, those of Beni Hassan—about 2100 B.C.—in which are represented certain Asiatic people wearing costumes irregularly patterned with spots, stripes and zig-zags, which may have been more readily stamped than embroidered or woven. A rather more complicated and orderly pattern well suited to stamping occurs in a painting about 1320 B.C., of Hathor and King Meneptha I. Herodotus, referring to the garments of inhabitants of the Caucasus, says that representations of various animals were dyed into them so as to be irremovable by washing. Pliny describes "a very remarkable process employed in Egypt for the colouring of tissues. After pressing the material, which is white at first, they saturate it, not with colours, but with mordants that are calculated to absorb colour." He does not explain how this saturation is done. But as it is clearly for the purpose of obtaining a decorative effect, stamping or brushing the mordants into the material may be inferred. When this was finished the cloth was "plunged into a cauldron of boiling dye" and "removed the next moment fully coloured." "It is a singular fact, too, that although the dye in the pan is of one uniform colour, the material when taken out of it is of various colours according to the nature of the mordants that have been respectively applied to it." Egypto-Roman bits of printed stuffs from Akhmîm exhibit the use, some three hundred years later than the time of Pliny, of boldly cut blocks for stamping figure-subjects and patterns on to textiles. Almost concurrent

[1] When Cortes conquered Mexico he sent to Charles V. cotton garments with black, red, yellow, green and blue figures. The North American Indians have a mode of applying patterns in different colours to cloth (see Parnell's *Dyeing and Calico Printing*, p. 12).

with their discovery was that of a fragment of printed cotton at Arles in the grave of St Caesarius, who was bishop there about A.D. 542. Equal in archaeological value are similar fragments found in an ancient tomb at Quedlinburg. These, however, are of comparatively simple patterns. Other later specimens establish the fact that more important pattern-printing on textiles had become a developed industry in parts of Europe towards the end of the 12th and the beginning of the 13th century.

According to Forrer (*Die Kunst des Zeugdrucks*, 1898) medieval Rhenish monasteries were the cradles of the artistic craft of ornamental stamp or block cutting. In rare monastic MSS. earlier in date than the 13th century, initial letters (especially those that recurred frequently) were sometimes stamped from hand-cut blocks; and German deeds of the 14th century bear names of block cutters and textile stampers as those of witnesses. Between the 11th and 14th centuries there was apparently in Germany no such weaving of rich ornamental stuffs as that carried on in Spain and Italy, but her competitive and commercial instincts led her to adapt her art of stamping to the decoration of coarse textiles, and thus to produce rather rough imitations of patterns woven in the Saracenic, Byzantine and Italian silks and brocades. Amongst the more ancient relics of Rhenish printed textiles are some of thin silken stuff, impressed with rude and simplified versions of such patterns in gold and silver foil. Of these, and of a considerable number of later variously dyed stout linens with patterns printed in dark tones or in black, specimens have been collected from reliquaries, tombs and old churches. From these several bits of evidence Dr Forrer propounds an opinion that the printing of patterns on textiles as carried on in several Rhenish towns preceded that of printing on paper. He proceeds to show that from after the 14th century increasing luxury and prosperity promoted a freer use of woven and embroidered stuffs, in consequence of which textile-printing fell into neglect, and it was not until three centuries later that it revived, very largely under the influence of trade importing into Europe quantities of Indian printed and painted calicoes.

Augsburg, famous in the 17th century for its printing on linens, &c., supplied Alsace and Switzerland with many craftsmen in this process. After the revocation of the edict of Nantes, French refugees took part in starting manufactories of both painted and printed cloths in Holland, England and Switzerland; some few of the refugees were allowed back into France to do the same in Normandy: manufactories were also set up in Paris, Marseilles, Nantes and Angers; but there was still greater activity at Geneva, Neuchâtel, Zürich, St Gall and Basel. The first textile-printing works in Great Britain are said to have been begun towards the end of the 17th century by a Frenchman on the banks of the Thames near Richmond, and soon afterwards a more considerable factory was established at Bromley Hall in Essex; many others were opened in Surrey early in the 18th century. At Mulhouse the enterprise of Koechlin, Schmatzer and Dollfus in 1746, as well as that of Oberkampf at Jouy, led to a still wider spread of the industry in Alsace. In almost every place in Europe where it was taken up and followed, it was met by local and national prohibitions or trade protective regulations and acts, which, however, were gradually overcome.

Towards the end of the 18th century a revolution in the British manufacture of printed textiles was brought about through the invention of cylinder or roller printing from metal plates. This is usually credited to Oberkampf of Jouy, but it seems to have also occurred to a Scotsman named Bell, and was successfully applied in a large way about 1785 at Monsey near Preston. From this and the calico-printing works at Manchester in 1763, and in Scotland in 1768, the present huge proportions of the industry in the United Kingdom have grown.

Illustrations accompanying this brief account merely indicate a few types of patterns used in various European countries up to the beginning of the 19th century. Typical specimens of East Indian painted and printed calicoes for coverlets and other draperies are shown in the Indian division of the Victoria and Albert Museum. These are *sui generis*, and therefore differ from the bulk of Western prints on chintz, cretonne, &c., which together with a less quantity of printing on satin, silk, velvet, crêpe and the like are principally from adaptations of weaving patterns. An interesting series of over 2500 patterns, chiefly of this character, was made by M. Corimand between 1846 and 1860, and is preserved in the National Art Library at South Kensington. For many years of the latter part of the 19th century, William Morris designed and produced attractively ingenious floral and bird patterns, admirable in contrasts of bright colours, frequently basing his arrangement of crisply defined forms in them upon that of Persian surface ornament. His style, which on its appearance struck a distinctive note, has very considerably affected numbers of British and foreign designers of printed patterns whether for textiles or wall papers.

The portion of linen hanging or valance given in fig. 1 (Plate I.) comes from an ancient cemetery at Akhmîm in Upper Egypt. The linen dyed blue bears ornamentation with figures undyed or "reserved," through the previous application to it, by means of an engraved block, of some such saturating fluid as that mentioned by Pliny. The design and cutting of the block were no doubt the work of Coptic artificers, the style of the composition being Egypto-Roman of the 5th century A.D. On the child's tunic dyed blue (fig. 2) the simple trellis and blossom pattern is similarly produced by the "reserve" process, and the specimen is of the same *provenance* as that of fig. 1. It is perhaps rather earlier in date, *i.e.* 4th century A.D. Fig. 3 is from a fragment of red silk printed in red, green and black from wood-blocks, thus illustrating another method of applying colours to textiles. It is probably of Rhenish work in the 12th or 13th century, and came from the Eifel district. The ornament, however, is a survival of a scheme of pattern which was in use in Perso-Roman weavings as early as the 7th century A.D. Fig. 4 shows a piece of red silk printed with a Rhenish adaptation of a 13th-century North Italian weaving pattern possessing earlier Byzantine features. The design in fig. 5 is another Rhenish version of a richer style of 14th-century North Italian weaving. An advance in refinement of block-cutting is seen in fig. 6, a Rhenish adaptation of a 14th-century North Italian pattern often employed in brocade weaving of that period. The pattern in fig. 7 (Plate II.) is typical of a style introduced during the 15th century in sumptuous damask satins, and velvets woven at Florence, Genoa and Venice. Very different is the style exemplified in fig. 8, taken from a Dutch 17th-century "Indienne," the trade name for such prints. The repeated wide and narrow stripes recall a scheme of design which the Siculo-Saracens of the 11th century employed for brocades; the intertwining floral ornament closely resembles such as occurs in 16th-century Indian painted and printed cottons. Fig. 9 is a 19th-century Italian reproduction of the Persianesque spreading tree device often used in Indian palampores from the 16th century onwards to the present day. These, however, were either painted or printed from wood-blocks, whereas for this Italian copy engraved metal plates were used, after the manner of the process which was started, as already mentioned, by Oberkampf and Bell in the 18th century. The remaining figures 10, 11 and 12 are from stuffs metal-printed with subjects of a pictorial character which had a vogue for some time. In fig. 10—a French print—are family groups: shepherds and shepherdesses with their flocks; children at play; buildings, rocks, trees, &c.; the decorative effect of which, for the purposes of curtains and furniture covers, resulted mainly from the ordered repetition of these somewhat unrelated details. A landscape with a Chinese pagoda was repeated in lengths of the English cotton print, a piece of which was cut to fit the back of a chair as in fig. 11. Fig. 12 is from a linen panel printed in colours with a stipple engraving to be used as a small fire screen. The style reflects the pseudo-classical taste of the end of the 18th century in England. Beneath the group of figures in the original is an inscription, "London, engraved and published, August 1, 1799, by M—Bost No. 207 Piccadilly." This sort of printing has practically disappeared: it was unsuitable for manufacture on a large scale.

TEXTUAL CRITICISM, a general term given to the skilled and methodical application of human judgment to the settlement of *texts*. By a "text" is to be understood a document written in a language known, more or less, to the inquirer, and assumed to have a meaning which has been or can be ascertained.

The aim of the "textual critic" may then be defined as the restoration of the text, as far as possible, to its original form, if by "original form" we understand the form intended by its author.

Texts may be either *autographs* or they may be *transmitted* texts; the latter, again, being *immediate copies* of autographs or *copies of copies* in any degree.

Autographs (which may be taken to include whatever, though not actually in the writing of its author, has been revised and attested by him) are not exempt from the operations of textual criticism. Editors of journals remove the slips of the pens of their contributors; editors of books, nowadays usually in footnotes, the similar lapses of their authors. With this branch of textual criticism, however, modern scholarship is not largely concerned. Not so with *immediate copies*. Textual criticism is called upon to repair the mischief done to *inscriptions* (texts inscribed upon stones) by weathering, maltreatment or the errors of the stone-cutter. Any great collection, such as the *Corpus* of Latin inscriptions or the similar *Corpus* of Greek, will show at once its activity and ability in this direction.

The chief field of textual criticism is elsewhere. The texts of the older authors which have come down to us were written for the most part not on stone but on papyrus, parchment or other perishable material. Of these several copies had to be made, both by way of prevention against the wear and tear of use and as a means of satisfying the desire of other persons than the original possessor to be acquainted with their contents. Had the copies made of ancient writings been mechanical reproductions of the originals, such as the photographic facsimiles of modern times, there would have been little here for textual criticism to do. The ancient texts have not come to us in this way, but through copies made by the human hand directed more or less by the human intelligence. Now a copy made thus can in no circumstances be a quite exact rendering of that from which it is copied or its *exemplar*. A copy, *qua* copy, can never be the equal of the exemplar, and it may be much its inferior. This deterioration increases with the number of successive copyings. Let us suppose that from a text which we will call A a copy has been made which we will call B, and from this again a copy which we will call C. If the copyist of B goes wrong once and the copyist of C twice in a hundred times, then, assuming that there is no coincidence or cancelling of errors, the relative correctness of the three texts A, B, C will be 100 (absolute correctness), 99 and 97·02. If C had made his copy direct from A, his percentage would have been 98. The importance of this must be borne in mind when we are dealing with *transmitted texts*, which have passed through many stages of copying.

In the *Epidicus* of Plautus, I. I. 10, the right reading *habitior*, "more portly," has been preserved to us by Donatus, an ancient commentator on Terence (*Eunuchus*, 2. 2. 11). It was corrupted to *abilior* by omission of the *h* and confusion of *t* and *l*, and this corruption, which is attested by the oldest extant copy, the Ambrosian palimpsest, was still further corrupted in the other copies to *agilior*.

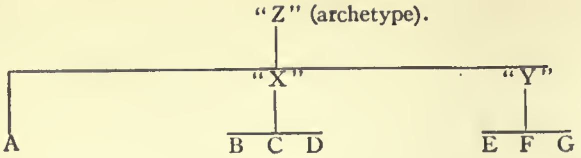
The first step towards the restoration of a text is the examination of the evidence upon which it is or is to be based. This begins with the investigation of its traditional or transmitted form. For this we have usually to rely upon *manuscripts* (MSS.). By manuscripts (*q.v.*) we understand copies of the text made before the art of printing came into general use. These may be either *extant* or *non-extant*. The evidence of extant manuscripts must be ascertained by *collation*. To collate a manuscript is to observe and record everything in it which may be of use towards determining what stood in the source or the sources from which it is derived. A manuscript is not usually a clean or single piece of writing; it is commonly found to contain alterations by erasure, addition or substitution. Such alterations may be due to the writer or writers of the MS., called the *scribe* or *scribes*, or to some other person or persons (for there may be several) called *correctors*. The relative importance of these corrections, it is obvious, may be very different. It is therefore necessary to distinguish the different *hands* which have been at work on the manuscript. Account must also be taken of the number of lines in each page, the number of pages in each quire, of gaps or lacunae in the manuscript, and so forth. The work cannot be considered complete till all the extant manuscripts have been collated or at least examined.

When this is done we shall have the materials for pronouncing a judgment upon the text as *directly transmitted*. Perhaps there is only one extant MS. of the text, as in the case of the *Mimes* of Herodas and the *Annals* and *Histories* of Tacitus. Then this part of our work is done.

But often we have to take account of a number, and it may be a large number, of manuscripts, whose respective claims to attention we must determine. In the first place we shall discard all manuscripts which are *derived* by copying *from other extant manuscripts*. If a MS. is immediately or ultimately derived by copying from another MS., it cannot, *qua* copy, tell us anything that we do not know already if the latter MS. is known to us. But how can we tell that a MS. is so derived? It must be later than the other MS., *and* the similarity between them must be such as to permit of no other explanation. In the absence of explicit dates the relative age of MSS. is often hard to determine, and hence the criterion of unmistakable resemblance is one of special importance. If the MSS. agree in singular though trivial mistakes, if they omit, apparently without motive, words and passages which other MSS. preserve, we shall be safe in pronouncing that there exists a close bond of connexion between them, and if one of them shows errors which, though strange in themselves, are quite intelligible when we see what stands in the other, then we shall be justified in concluding that the second is that from which the first is derived. For the proper consideration of such points a personal examination, *autopsy*, of the MSS. or of facsimiles of them, is very often indispensable. It was thought at one time that a MS. of the Latin poet Propertius at Naples (*Neap.* 268) might have independent value as an authority for the text. But its claims were disposed of when (amongst other facts) it was observed that at book iv. 8, 3, the MS. with which it most closely agreed (F, No. 36, 49 in the Laurentian library) had a gap at the beginning of the line and only the end words "uetus est tutela draconis," with the marginal note "*non potuit legi* in exemplari hoc quod deficit," and that *Neap.* 268 gives the line as follows, "*non potuit legi* uetus est tutela draconis."

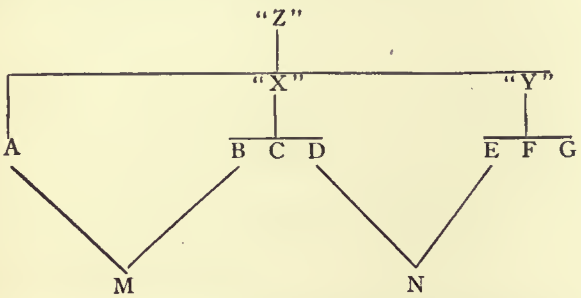
Accident apart, *identity of reading implies identity of sources*. The source of a transmitted reading may undoubtedly be the author's autograph: but if not, then it is some MS. in the line of transmission.

The peculiar resemblances of two MSS., though not sufficient to warrant the derivation of either from the other, may be sufficient to establish some connexion between them. From the axiom which has just been cited it follows that this connexion can be due only to community of source, and we thus arrive at the idea of *families of MSS*. Suppose that a text is preserved in seven MSS., A, B, C, D, E, F, G. If we find that of these A stands apart, showing no great similarity to any of the other six, while B, C, D on the one side, and E, F, G on the other, much resemble each other though differing considerably from the rest, we may express this by saying that B, C, D form a "family" descended from a hypothetical common "ancestor" which we may call X, and E, F, G another "family" descended from a hypothetical "ancestor" which we may call Y. The readings of X which can be deduced from considering the agreements in B, C, D will be of higher antiquity and of greater external authority than any of the readings in B, C, D taken singly. And similarly for the readings of Y and those of E, F, G. Nor shall we stop here: but we shall further compare the readings of X and Y with each other and with those of A, and thus deduce the readings of a still more remote ancestor which we may call Z. Z will be the *archetype* of all our existing MSS., and we may embody our results in a *pedigree* of manuscripts or *stemma codicum* as follows:—



If we have done our work properly, the texts that we arrive at for X and for Y will be freer from error than the texts of the separate members of the families B, C and D, and E, F, G respectively, and that of Z freer from error than that authenticated by any existing MS.

The procedure, however, is by no means always so simple. That a text may be improved by the comparison of different MSS. is not a modern discovery. It has long been known, and the knowledge has led to the production of what are known as *conflated manuscripts* or *Misch-codices*. These are MSS. produced by "crossing" or "intermixture." In the following stemma M and N are "mixed" or "conflated" MSS., being formed by the blending of readings from the "pure" or "unmixed" codices A, B and D, E respectively.



Intermixture may take place to any extent, and the more of it there has been the more difficult does it become to trace the transmission of a text.

Whether crossing improves a given text or not depends ultimately on the knowledge and the judgment of the crosser, and these will vary indefinitely. On the whole it is probable that it does, provided it is not accompanied by other attempts at improvement. If it be, as may very well be the case, the text will probably suffer. For but a small proportion of scholars' corrections are really amendments, and a far smaller proportion of scribes'.

The "genealogical" method, as we may call it, cannot in strictness be applied to conflated MSS., as their mutual relations can rarely be with certainty disentangled. But it is often possible to detect in such MSS. a common strain, shown by their agreement in peculiar corruptions or in probable readings when these latter would have been hard to discover by conjecture. This is practically an application of the method to a portion of such manuscripts.

A special value attaches to a conflated codex when one of the MSS. from which it has been compounded has perished and its readings are thus otherwise irrecoverable. This is exemplified in the *Neapolitanus* of Propertius, a manuscript now at Wolfenbüttel.

It not unfrequently happens that good or instructive readings are found in manuscripts which are in general of small trustworthiness (see below), and whose relations to the general tradition it is not worth while to investigate. These readings may be cited by the name of the MS., or if still greater brevity is required as the readings of inferior MSS. (*deteriores*), or, as is frequently done, by the symbol $\mathcal{S}$.

Non-extant Manuscripts.—Some of the most valuable of ancient MSS. have disappeared since their discovery in modern times. When this has happened we have to rely upon mere copies, many times of inferior quality, or upon the information which old scholars have given us respecting them. In the latter case what we have are not "collations," for the art of collation was not understood till the 19th century, but selections or "excerpts" of readings which we have reason to fear are often imperfect and erroneous. Further, it must not be assumed that all readings which are cited as being "*ex uetustis codicibus*" are necessarily from older or better MSS. than we now possess or indeed from MSS. at all. Scholars since the Renaissance have not always been above inventing codices to obtain currency for their own conjectures. The codices of Bosius (1535–1580) are just as imaginary as the "old plays" which appear as the source of so many of the quotations that head the chapters of the Waverley novels, and suspicion rests on Barth, Lambinus and others.

Some texts and portions of texts of ancient writers are now only known from printed books. The metrical treatise of Terentianus is now preserved in the *editio princeps* (1497) alone. All known MSS. of Silius Italicus have a considerable gap in the 8th book, first filled up on the authority of Jac. Constantius (1503), and not printed with the rest of the poem till the edition of Aldus (1523). The early printed books are often called by old scholars *codices impressi* (*typis*), "printed manuscripts," a phrase which at first seems curious to us but becomes perfectly intelligible when we examine these *codices impressi* and observe how closely they follow the *codices scripti*.

By the methodical employment of these means we shall arrive at a text different from any existing one. It will not be the best one, possible or existing, nor necessarily even a good one. But it will be *the most ancient one* according to the *direct line of transmission*, and the purest in the sense of being the freest from traceable errors of copying and unauthorized improvements.

The textual critic has occasionally to deal with the effects of *oral* transmission. A text so transmitted must in the lapse of time be profoundly though insensibly modified, its forms and expressions modernized, and, if widely disseminated, local variations introduced into it. This is the case with the Homeric poems, the ascertainment of the original form of which is a task beyond the powers of criticism. Even where, as in the Vedas, the sacred books of India, there is proof that the work has been transmitted without change through many centuries, the existence of unintelligible passages and unmetrical verses shows that here too there is work for textual criticism to perform, though in the opinion of most scholars it should be confined to the restoration of such forms as would be unconsciously and inevitably corrupted through changes of pronunciation and the like.

The invention of *printing* has naturally limited the province of textual criticism, and modified its operations. The writer's autograph, if it is preserved after it has been through the hands of the printer, has seldom more than an antiquarian value. As a source for the text it is superseded by the printed edition, and if there is more than one, then by the latest printed edition, which has been revised in proof by the author, or, in certain cases, by his representative; and the task of the textual critic is restricted to the detection of "misprints," in other words, of errors which the compositor (the modern analogue to the scribe) has made in "setting up" the manuscript, and which have escaped the notice of the proof-reader and the author or his representative. If, however, this revision has been neglected or incompetently performed, the number of such mistakes may be considerable.

Another question with which the textual critic of modern authors must be prepared to deal is the relative importance of different editions, each of which may have a prima facie claim to be considered authentic. Thus Shakespearean criticism must decide between the evidence of the first folio and the quartos: the critic of Shelley's poems must consider what weight is to be attached to the readings in the posthumous edition by Mrs Shelley, and in unpublished transcripts of various poems. Where there is great or complicated divergence between the editions, as in the case of Marlowe's *Faustus*, the production of a resultant text which may be relied upon to represent the ultimate intention of the author is well-nigh impossible.

For the bettering of the *transmitted text* we can call in aids of a partial or subsidiary character which are known in general as *testimonia*. Such are *Anthologies* or collections of extracts. The oldest authority for an epithalamium of Catullus (62) is an anthology at Paris written in the 9th century.

Translations from one language into another may help to fix the reading of the original, or this again that of the translation.

In Shelley's *Prometheus Unbound*, ii. 5, 54,—"Child of Light! thy limbs are burning | Through the vest which seems to hide them"—"limbs" is supported against "lips" (ed. 1) by "*membre*" in the Italian prose version made by Shelley himself: and similarly in l. 52 "looks" (not "locks") by the rendering "sguardi." In his translations of Euripides' *Cyclops*, 381, "a bowl | Three cubits wide and four in depth, as much | As would contain four amphorae" the Greek original clearly points to "*ten* amphorae" and *four* may have come from the previous line.

In *direct quotations*, either of passages or single words, and either with or without the author's name, we must be sure that the writer is quoting exactly.

A couplet of Propertius is written upon the walls of Pompeii in the following form: "Quisquis amator erit, *Scythiae* licet ambulet oris, | Nemo *adeo ut feriat*, barbarus esse uolet." Here the manuscripts have "*Scythicis*"—"*deo ut noceat*," of which *deo* is rejected by every one in favour of the Pompeian reading, but *Scythicis* and *noceat* are retained on the ground that they are in themselves better than the Pompeian readings, which may be simply due to lapse of memory. In Shelley's *Julian and Maddalo*, 40, —"(talk) such as once, so poets tell, | The devils held within the *dales* of Hell | Concerning God, freewill and destiny,"—*vales* has been suggested to make it harmonize with the passage of Milton to which reference is made: but the argument is not conclusive.

Parodies may prove of service in restoring the form of what is parodied or this in restoring the parody. So also *obvious imitations*, especially in a highly imitative literature such as Latin poetry. The connexion of the passages must in all these cases be unmistakable.

In Homer, *Iliad*, i. 4 seq., Aristarchus had the common reading αὐτοὺς δὲ ἑλώρια τεῦχε κύνεσσι | οἰωνοῖσί τε πᾶσι, but another Homeric critic of note, Zenodotus, read δαῖτα for πᾶσι, and this is supported by the obvious imitation in Aeschylus, *Supplices*, 800, who has ὄρνισι δεῖπνον.

The support which a reading gains from the evidence of the directly transmitted text *and* from the auxiliary testimonia may be called its *documental probability*. To restore a text from the documental evidence available we must know and weigh the causes which tend to vitiate this evidence in its various kinds. We shall speak first of those which affect the *direct* transmission of texts. These are either external or internal.

External.—A text may become illegible through damp or constant thumbing; portions of it may be torn away; if it is in book form, leaves or whole quires may be detached and either lost or misplaced. When this has taken place on a considerable scale, the critic is helpless; but minor injuries may sometimes be traced and remedied. The weakest parts of a MS. book were the outer margins; and hence the beginnings and the ends of lines, whether of verse or prose, were specially liable to injury. It obviously makes a difference upon which side of a leaf, whether on the verso or the recto, a line was written. Hence the determination of the paging of the archetype (as was done for the archetype of Lucretius by Lachmann) has more than a merely antiquarian value. In ancient classical MSS. the first letters of poems in verse and of paragraphs in prose usually, and the initial letters of lines in verse occasionally, were written separate and by another person than the scribe (who was called the *rubricator*), and hence were apt to be omitted. Other external circumstances may prejudicially affect a text. The copy from which Shelley's *Julian and Maddalo* was printed was written on very narrow paper, and the punctuation marks at the ends of the lines were frequently omitted.

Internal.—These errors arise from the default of the scribe or copyist, and, in the case of printed books, the compositor.[1] They are very numerous. They may be roughly arranged according to the degree in which the volition of the copyist is absent or present, as involuntary or mechanical, semi-voluntary and voluntary; or again as they affect single signs (letters, figures or symbols), words, lines or even larger units such as sentences or paragraphs.

[1] For the convenience of the general reader these errors have been illustrated as far as possible from English authors and especially from the poems of Shelley (ed. Hutchinson).

Simple Errors of the Eye.—(*a*) Confusions of letters. These are very numerous, and different in different scripts or styles of writing (see PALAEOGRAPHY). Thus the Roman letters *E* and *F* are liable to be confused in capital script, but not in cursive (*e*, *f*), *C*, *G*, in capitals, *c*, *e* in the cursive writing called Caroline minuscule, *c*, *t*, in the angular cursive of the 13th century and later. Texts which have had a long history will often show by the letter-confusions which they exhibit that they have passed through several distinct stages of copying. It is to be observed that two different styles of writing are often found in the same manuscript, the difference being utilized for the purposes of distinction. Thus in Greek cursive MSS. notes were often written in uncials; the use of majuscules or capitals for headings and for the initial letters of lines is well known. (*b*) Omissions of letters. (*c*) Shiftings of letters, sometimes by syllables. This is very common in half intelligent or half mechanical copying. In printing we get the disarrangement of type which is known as "pie." (*d*) Confusions of symbols and abbreviations.

(*a*) Examples of confusion of capital letters from Shelley's poems are: *Prometheus*, i. 553, "*M*ark that outcry of despair" for "*H*ark"; *Hellas*, 472, "*H*old each to the other in loud mockery" for "*T*old." Of *cursive letters: Marenghi*, 130, "the d*im* ocean" for "the d*un* ocean"; *Letter to Maria Gisborne* 126, sqq., "above | One chasm of Heaven smiles like the *age* of Love | On the unquiet world" for "*eye*." (*b*) *Translations from Goethe's Faust*, sc. i. 46, "To live more beas*t*ily than any beast," for "beas*tl*ily"; ii. 165, "eye" for "ey*ne*" (in spite of the rhyme with 163). (*c*) *Prometh.*, iv. 575, "Neither to change, nor f*la*tter, nor repent," for "falter." In Latin MSS. we often find a mere jumble of letters. (*d*) Confusion of words through abbreviations is very common in ancient MSS., where they were much employed. At a famous place in the doxology of 1 Timothy iii. 16, the MSS. vary between ὃς (or ὃ) and Θεός. In uncial writing OC (ὃς) might easily be miswritten or altered to ΘC (Θεός) or vice versa.

Loss of Letters, Syllables, Words or Lines, through Similarity of Writing: Homoeographon.—When similar letters or groups of letters stand next to each other, one of these is liable to be omitted. This is the simplest case and is called *haplography*.

Similarity operates differently if the similar groups stand in different lines of the exemplar. Then the copyist's eye is apt to slip from the first of two similarly written groups to the second; and he will thus omit all that is between. The term *homoeoteleuton* ("similarity of ending") is often used of these omissions, but it is not adequate, as similarity anywhere may produce the same result.

Examples of *homoeographon* and *haplography*. Shelley's *Cenci*, v. 4, 136, "whose love *was* [*as*] a bond to all our loves": a similar omission in *Witch of Atlas*, 599. In *Stanzas written in Dejection near Naples* the two lines 4, 5, "The purple noon's transparent *might*, | The breath of the moist earth is *light*," were printed in the 1st edition, "The purple noon's transparent *light*," owing to the *homoeographon* "might" "light."

Omissions through Simple Negligence.—Groups of letters, words, syllables and lines are often omitted without any contributory cause. Short words or such as are not necessary to the sense are especially prone thus to disappear.

Examples of *omission*. Shelley's *Prometheus*, iii. i, 70, "No refuge! No appeal! Sink with me [then];" *Cenci*, i. i, 26, "Respited [me] from Hell! So may the Devil | Respite their souls from Heaven!"; *Hellas*, 657, "Bask in the [deep] blue noon divine"; *Julian and Maddalo*, 218, where "Moans, shrieks, and curses, and blaspheming prayers" is absent in the earlier editions though required for the rhyme; so lines 299–301 of the *Letter to Maria Gisborne*.

Repetitions: Dittography.—Letters, groups of letters, words and lines may be written twice (or even oftener) instead of once.

Other repetitions of words already written and anticipations of words yet to be written are also found, through the scribe's eye wandering into the preceding or the following context. Wherever the word or group of words repeated is not the one that he has just copied loss is liable to occur.

Dittography is common enough in manuscripts but is usually detected in reading proofs. In the unique MS. of Cicero's treatise *De Republica*, 2, 33, 57, *secutus* appears as "*secututus secutus.*" Other kinds of repetition are Shelley's *Witch of Atlas*, 611 seq., "Like one asleep in a green hermitage, | With gentle *sleep* about its eyelids playing" (*sleep* for *smiles* has come from the previous line); *Revolt of Islam*, 4749, "Where" for "When" appears to have come from "*Where*" in 4750 or 4751. Often the word thus extruded is irrecoverable; *Ginevra*, 125 sqq., "The matin *winds* from the expanded flowers | Scatter their hoarded incense and awaken | The earth, until the dewy sleep is shaken | From every living heart which it possesses | Through seas and *winds*, cities and wildernesses"; the second "winds" is a repetition of the first, but what should stand in its place,—"lands" or "strands" or "waves" or something else—no one can say.

Confusions of Words.—Words are not only changed through confusion of single letters or abbreviations, but also through general resemblance or (a semi-voluntary change) through similarity of meaning.

Shelley, *Prometheus*, ii. 2, 53: "There streams a plume-uplifting wind" for "steams." In Shelley's lines, *When the lamp is shattered*, vv. 5–6, "When the lute is broken, | Sweet *tones* are remembered not," the printed edition had "notes" for "tones." In Mrs Gaskell's *Cranford*, ch. xiv. (near the end), "The lunch—a hot savoury mutton-chop, and a little of the cold *loin* sliced and fried —was now brought in" is the reading of most if not all the editions; but "*loin*" should be "lion," the reference being to the pudding, "a lion with currant eyes," described earlier in the chapter. In Shelley's "Evening: Ponte al Mare, Pisa," 20, "By darkest barriers of *enormous* cloud" for "*cinereous*"; "Hymn to Mercury" (trans.), 57, "And through the tortoise's hard *strong* skin" for "*stony*." Shelley's "The Boat on the Serchio," 117, "woods of stunted *fir*" for "*pine*" which the rhyme requires; *Prince Athanase*, 250, "And sea buds burst *beneath* the waves serene" for "*under*."

The same character frequently attaches to *transpositions of words and parts of words.* The copyist does not as a general rule consciously intend a change, but he falls into one through the influence of dominant associations. He substitutes an order of words which, in respect of syntax, metre or rhythm is more familiar to him.

Transpositions of words, if not purely accidental, as in Chaucer, "Parson's Tale," p. 689 (ed. Skeat), "God yaf (gave) his benison to *Laban* by the service of Jacob and to *Pharao* by the service of Joseph," where the MSS. transpose *Laban* and *Pharao*, are generally to a more usual order, as in Shelley's *Witch of Atlas*, 65, "She first was changed" to "she was first changed." An instance of transposition of words *in part* is in Shelley's "Invocation to Misery," l. 27, "And *mine* arm shall be *thy* pillow," where the 1st ed. had "*thine* arm" and "*my* pillow."

Faulty Divisions of Words.—These will generally imply an exemplar in which the words were without any division or without a sufficient one. Under this head we may class errors which arise from the omission or the insertion of such marks as the apostrophe and the hyphen.

Examples of *wrong division* of words. Chaucer's *House of Fame*, iii., 1975, "Of good or misgovernement" which should be "mis (*i.e.*, bad) governement"; Shelley's *Prometheus*, iii. 2, 22, "Round many peopled continents" for "many-peopled," *ib.* 26, "the light laden moon" for "light-laden"; *Revolt of Islam*, 4805, "Our bark hung there, as *one* line suspended | Between two heavens," for "*on a* line."

With this we may class *faulty division of sentences*. Wrong punctuation is a common error and usually easy to correct.

As an example of mispunctuation we may take Shelley's *Triumph of Life*, 188 sqq., "'If thou can'st, forbear | To join the dance, which I had well forborne' | Said the grim Feature of my thought 'Aware | I will unfold,'" &c., for "said the grim Feature (of my thought aware) 'I will unfold.'"

Grammatical Assimilations.—These are often purely mechanical errors: but they may be semi-voluntary or even voluntary, the copyist desiring to set the syntax right.

Examples: Shelley's *Rosalind and Helen*, 63, "A sound from *thee*, Rosalind dear" instead of *there; Mask of Anarchy*, 280 seq., "the daily strife | With common wants and common cares | Which *sow* the human heart with tares," for "*sows*."

Insertions (or Omissions) of Seemingly Unimportant Words.—These, inasmuch as they must often import some judgment on the sense of the passage copied, will be frequently semi-voluntary if not voluntary.

Examples: Shelley, *Prometheus*, iii. i, 5, "The soul of man like [*an*] unextinguished fire." So in *Triumph of Life*, 265, "Whom from the flock of conquerors | Fame singled *out* for her thunder-bearing minion," *out* seems to be due to the compositor.

False Recollections.—The passage which a copyist is reproducing may suggest to him something else and he will write down what is thus in his mind instead of what is before his eyes.

There is a noteworthy instance in Horace, *Odes*, iii. 18, 11 seq., "*festus in pratis uacat otioso* | *cum boue pagus*" where some MSS. give *pardus*, a reminiscence of Isaiah xi. 6, "The *leopard* (*pardus*) shall lie down with the kid." In iv. i. 20, for "*trabe citrea*" many MSS. have "*trabe Cypria*," which occurs in i. 1, 13.

Incorporation of Marginalia.—The copyist may erroneously suppose that something written in the margin, between the lines or at the top or the foot of the page which he is copying, is intended to be placed in the text. The words so incorporated may appear side by side with the genuine reading or they may expel it.

In Horace, *Odes*, iii. 27, 47, "amati | cornua *monstri*" (of the bull which carried off Europa), more than one MS. has "cornua *tauri*," an explanation of *monstri*. The celebrated passage about the three heavenly witnesses inserted in the Epistle of St John (v. 2) seems to have been originally a comment explanatory of the text.

Transpositions of Lines and Passages.—This kind of transposition is really arrested loss. An accidental omission is discovered, and the person responsible, or another, places what is omitted in the margin at the foot of the page or in some other part of the text, usually adding a mark to show where it ought to have been. The next copyist may easily overlook this sign and thus the passage may be permanently displaced.

In Chaucer's *Canterbury Tales*, most MSS. place the couplet, "And eek of many another maner cryme | Which nedeth nat rehercen at this tyme," which should stand after v. 8 of the "Friar's Tale," in the Prologue to the Tale before the fourth line from the end. In the "Monk's Tale" a block of 88 lines (3565–3652) is transposed in most MSS. to follow 3956.

Interpolation.—This is the deliberate alteration of an exemplar by way of substitution, addition or omission, but when it takes the particular form of omission it is naturally very hard to detect. Interpolation then always has a motive. The most frequent motive is the removal of some difficulty in the sense, expression or metre of the text, and especially obvious gaps or corruptions which the interpolator endeavours to fill or to heal. Fraudulent interpolation, whether the fraud be pious or otherwise, does occur, but is comparatively rare. The removal or the mitigation of objectionable matter is also occasionally found. Interpolation is then a voluntary alteration, but in practice it is often hard to distinguish from other changes in which its motive is absent.

The usual character of scribes' alterations is well illustrated by a passage in Bacon's *Advancement of Learning*, II. xix., "For these critics have often presumed that that which they understand not is false set down: as the Priest that where he found it written of St Paul *Demissus est per sportam*" [Acts ix. 25] "mended his book, and made it *Demissus est per portam*, because *sporta* was an hard word, and out of his reading." Shelley in *Triumph of Life*, 201 seq., wrote, "And if the spark with which Heaven lit my spirit | Had been with proper *nutriment* supplied," but the printed editions made it "*sentiment*." The transcript used for the printed edition of *Marenghi* apparently often corrupted what was rare and strange to what was commonplace; *e.g.*, l. 119, "dewglobes" to "dewdrops." Interpolation is sometimes due to an inopportune use of knowledge, as when a quotation or a narrative is made to agree with what the interpolator has read elsewhere. The text of the Septuagint, a translation of the Old Testament made from MSS. older than those accessible to Origen, was much altered by him in order to make it conform more closely to the Hebrew text with which he was familiar, and in the Synoptic Gospels changes are found, the aim of which is to "harmonize" the accounts given by the different evangelists. Deliberate alteration is occasionally due to disapproval of what stands in the text or even to less creditable reasons. There is an old and seemingly trustworthy tradition that some lines in Homer's "Catalogue of the Ships," *Iliad*, ii. 553–555 and 558, were introduced there to gratify the vanity or ambition of the Athenians. Insertions of this or of a similar character may be of almost any length, from a few words to a whole chapter or a complete poem. Literary forgery has never set any bounds to itself, and the history of every literature will supply examples of entire works being foisted upon authors and personages of repute. A notable one was the *Epistles* of *Phalaris*, a late Greek forgery, demonstrated to be such by Bentley in a treatise which is a model of what such a demonstration should be.

Special Conditions conducing to Corruption.—The chief of these is strangeness or difficulty in the matter to be copied. Proper names, technical expressions, quotations from foreign languages, and frequent change of subject, are all likely to cause difficulty to a scribe and error in his work.

Careful and continuous regard to the various kinds of errors and defaults that are found in transcription will enable us to judge whether a reading which it is suggested stood in the archetype of our text is likely to have been corrupted to the reading, or readings, which stand in the extant manuscripts or editions. If it is, we say of this reading that it is *transcriptionally probable.*

Some precautions must be observed. First we must rule out any proposal which assumes confusions of letters and abbreviations which are not attested for the particular tradition. Secondly, since different scribes are prone to different kinds of error, we must ever bear in mind the particular failings of the scribes responsible for the transmission of our text as these failings are revealed in the *apparatus criticus.*

Maxims of criticism to which we may here refer are that "harder readings are better than easier" and that "the shorter reading is generally the truer." The first maxim is indisputable, provided we understand by "harder" *harder to the scribe*, and by "easier" *easier to the scribe.* The characteristic of scribes' emendations or interpolations is that they are superficial. Their mark is that at the time of their making they "combine the appearance of improvement with the absence of its reality" (Westcott and Hort, *New Testament*, i. p. 27). The second maxim refers to the well-known fact that accretions from marginalia, &c., lengthen and at the same time weaken a text.

The virtues of a scribe are *honesty* and *care* (or in a single word *fidelity*) and *intelligence.* But it is rare to find these combined in a very high degree, and out of them we can least easily dispense with fidelity. Paradoxical as it may seem, the mechanical corruptions of a stupid but faithful copyist may tell us more than the intelligent copyings of a less faithful one.

A nice question is how far *any* alteration of the text of the exemplar is compatible with fidelity. Is a scribe, who recognizes under a corruption the word certainly intended, to perpetuate the error of the exemplar? Considering the liability of corruption to breed corruption we can hardly blame him if he does not, and we may say that it is no derogation to his *fides* if he makes self-evident corrections. But with these he must stop.

At certain epochs in the transmission of literature systematic efforts have been made to improve the transmitted texts, and these efforts have naturally been accompanied by a good deal of emendation both successful and unsuccessful. Such an epoch was the revival of Latin and Greek learning in the 15th century, and a modern scholar would for that reason naturally prefer to have a manuscript to work on, which was written immediately before this epoch to one which was written immediately after it.

The fidelity of a scribe has to be judged chiefly by *internal* tests, and these are best applied to his work in passages where there is no reasonable doubt of the correctness of the transmitted text. But there are two tests of a more objective character that may be used—orthography, and indication of lacunae or other faults in his exemplar. A scribe who preserves in his spelling the traces of a bygone age is probably trustworthy. If faithful in small things, he is likely to be faithful in great. A scribe again who scrupulously records the presence of a lacuna or illegibility in what he is copying, inspires us with confidence in the rest of his work.

As regards the use of *testimonia*, it may be observed to begin with that their value must depend on the trustworthiness of the texts of the writers from whom they are taken, and further upon that of the text used by the translator, the excerptor or the quoter, about which we can know nothing for certain, though we may sometimes make probable inferences. In the case of quotations we must allow for failures of memory.

Many times in the course of his investigations the critic will be confronted with problems which cannot be resolved by considerations of transcriptional or documental probability. To take an instance already referred to, it is not clear at first sight whether in the couplet from Propertius *Scythiae* is more likely to be a misrecollection of some text of the 1st century A.D., or *Scythicis* some scribe's assimilation which made its way into the transmitted text in the course of the next thousand years.

This leads us to consider *Intrinsic Probability.* By this is meant the likelihood that the writer of our text would at the time of writing have written, or not have written, a particular thing. Two questions which may be separated, though they are not entirely distinct, are here involved. What was the meaning of the writer? And how did he express it? The sense may be clear though the words may no longer be determinable.

A reading may be impugned on a number of grounds: that it gives no sense or an inappropriate sense, that it involves a usage or an idiom not current at the assumed time of writing, or foreign to the reputed author, or to the style in which he then was writing, that it involves some metrical or rhythmical anomaly, or that the connexion of thought which it produces is incoherent or disorderly. These charges cannot be played off against each other. It is no answer to the objection that a reading in some Roman poet makes nonsense to say that its Latinity is perfect or its metre excellent. But they may reinforce each other, and to such corroboration great weight must be assigned.

To set the meaning of a passage in a foreign language before us we must frequently have recourse to *translation.* But this method of representation is a very imperfect one; we may easily impose on ourselves and others by strained and ambiguous renderings. A more subtle danger to which we are especially liable in the case of a dead language is that of our acquiescing in a sense which satisfies us but which would not have satisfied the ancient writer. Above all we must avoid applying our own standards of taste, style and morality to the judgment of the text before us. The textual critic has no concern with what the writer ought to have thought or said; his business is solely with what he did say or think or might have said or thought. Amongst the legitimate reasons for suspecting the correctness of a text are patent contradictions in a passage or its immediate neighbourhood, proved and inexplicable deviations from the standards for forms, constructions and usages (mere rarity or singularity is not enough), weak and purposeless repetitions of a word (if there is no reason for attributing these to the writer), violations of the laws of metre and rhythm as observed by the author, obvious breaks in the thought (incoherence) or disorderly sequence in the same (double or multiple incoherence).

Where the critic has ascertained the earliest form of a reading in his text, he will apply to it the tests of intrinsic probability. No part of a text can be considered exempt from this scrutiny, though for a very large part of it it may be dispensed with. It should, however, be here observed, that whoever takes a reading without investigation, on the authority either of a manuscript or of a great scholar, or of a number of scholars, ceases for the time being to be a textual critic.

After every such critical examination four conclusions are possible—acceptance, doubt, rejection and alteration. In other words, a critic may deliberately pronounce that what stands in the text represents what the author wrote or might well have written, that it is doubtful whether it does, that it certainly does not, or, in the last event, that it may be replaced with certainty by something that does. In the three first cases his judgment will be governed by considerations of intrinsic probability alone: but in the last it must regard transcriptional probability as well. No alteration of a text, or *emendation,* is entitled to approval, unless in addition to providing the sense and diction required, it also presents a reading which the evidence furnished by the tradition shows might not improbably have been corrupted to what stands in the text. These tests, and these alone, are emendations bound to satisfy; but others are often tacitly imposed upon them. Of this the transposition of lines is the most notable example. This kind of change is troublesome to estimate and inconvenient to adopt, as it involves placing passages where we are not accustomed to look for them; but to the question, did the author write the passage here or there? the matter of *our* trouble or inconvenience is wholly irrelevant. There is, however, one class of cases in which no conclusion may be drawn, documental and intrinsic probability both failing us. This is where two alternative readings, neither of which can have come from the other, have equal external support and equal intrinsic merit. Isolated discrepancies of this kind may be due to some accident to our text at a period now beyond our power to trace. Numerous and striking discrepancies may be due to the fact that there was more than one edition or recension of it in early times, or to the author leaving his work in such a condition that such discrepancies must inevitably gain currency. In the case of dramas, different acting editions will give rise to them.

Up to this point all schools of textual criticism are theoretically at least in accord. But here begins a divergence which has done more than anything else to discredit the study with the outside world. It emerges because in all judgments on textual matters it is presupposed that they will be acted on, that a reading accepted will remain in the text, a rejected one obelized, enclosed between brackets or removed, and, in this last case, something else substituted in its place.

The "conservative" critic's chief concern is for the safety of the traditional and by preference the transmitted text. He urges very rightly that if alteration is carried beyond a certain point it cuts away its own foundation, and so all certainty is destroyed. His objective is the minimum of change. And as the need of making a text compels some sort of decision in every case, the "doubtful" readings of the tradition, some of which on the evidence would be doubtfully accepted and others doubtfully rejected, will all appear with the accepteds in the text. As to alterations (emendations) that are less than certain, his attitude is clearly if somewhat crudely expressed in the dictum that it is better to leave in the text "what if not the original reading is at least the remains of it." The corresponding thesis of the opposite school would be that it is better to present to the reader something which the author might have written than something which he could not: or, in other words, that "stopgaps" should be preferred to débris.

An editor of a corrupt and disputed text may reasonably adopt either of two methods of procedure. He may present the text in the purest form which the external evidence warrants, and place all plausible suggestions for its improvement in notes or appendices. The text will be faithful but unreadable, and his work will be that of an honest man but of a textual antiquarian, not a textual critic, since he declines the duty of "the restoration of the text, as far as possible, to its original form." On the other method the editor will provide all necessary information about the evidence for the text in the notes of his critical apparatus; but in the text itself he will give whatever in each case is supported by the balance of the probabilities. Each and every case he will decide on its own merits and without reference to decisions upon the other cases not now before him. Special consideration will be paid to "doubtful" readings, which will be distinguished in his work as "doubtfully accepted" or "doubtfully rejected." Legitimate doubt arises when the evidence *pro et contra* of documental and intrinsic probability is equal, or nearly equal, or when documental probability points strongly to one side and intrinsic probability to another. Illegitimate doubt is the uncertainty of the doubter as to whether he has examined the whole of the evidence. Such doubt is much more frequently felt than acknowledged, and its effect upon critical work is highly injurious. On the one hand, it is apt to take refuge in an uncritical acceptance of the traditional readings, and, on the other hand, to produce a crop of hesitant and mutually destructive conjectures which a reader naturally resents as a needless waste of his time.

The so-called "conservative text" is neither an antiquarian's text nor a critic's text, but a compromise between the two. When it is conscientiously obtained, it is arrived at by handicapping, more or less heavily, intrinsic probability as compared with documental probability, or by raising the minimum of probability which shall qualify a reading for admission into the text until it is in agreement with the notions of the editor. Both of these procedures are arbitrary in their principle, and liable to be erratic in their application. The text will suffer whichever course is adopted, and it will suffer the more the more conservative is the editor, as may easily be shown. Thus, to take the latter one, if we suppose that of two editors of equal competence A requires a probability of four-fifths to admit a reading into his text and B a probability of three-fifths only, then in all the cases in which the probability lies between these two fractions B will be right seven times to A's three, while outside these limits there will be no difference between them.

Many persons appear to suppose that decisions upon doubtful points can be avoided by the expedient of leaving the traditional reading in possession of the text. The rule is a simple one and easy to apply. But owing to the constitution of the human mind it has consequences which possibly they have not contemplated. The great works of classical literature are not studied as pathological specimens, and they will be studied the less the more they contain to repel and disquiet the reader. If a corruption is left in a text when something might be substituted which would at least, as a "stopgap," give the sort of sense required, then one of two things must happen. Either the sense of the passage is blotted out for the reader and the conservation of the corruption is tantamount to the expunging of the rest of the sentence, or else he will obtain the required sense by wresting the meaning of the other constituents of the context until they furnish it. So far so good: the requisite sense has been obtained, but the price has now to be paid. And the price is that the reader's perception of the signification of the word or words so wrested is dimmed and impaired, and his power of discriminating and understanding them when he meets them again is shot with doubt and error. In dealing with writings in dead languages this is particularly mischievous.

There are two reasons in particular why the part which emendation plays in the shaping of Greek and Latin texts is apt to be overlooked. Most people take their notions of a classical book not from its traditional form but from a "received" or *vulgate* text. This in the case of most writings is fairly readable, because it has been purged by the continuous emendation of scholars during several centuries. But the received conjectures which make this text acceptable have no more authority in themselves than equally good conjectures which have not yet won their way into the text, and it is clearly illogical to treat a text largely built upon conjectures as if it were now beyond the reach of conjecture. Again, it has often happened that readings which have been discovered by conjecture, and as such received into a text, have afterwards been found to have the support of MSS. Thus in one speech of Cicero, *pro Caelio*, some thirty conjectures of critics were found to be attested by a single recently discovered MS. Such readings it is now commonly the practice to transfer to the credit of the MS. and to suppress the fact that they were originally discovered by emendation. These *confirmations*, as they are called, should be carefully recorded in all critical texts, inasmuch as they constitute the most striking justification of the critical method.

Some examples from Shelley's poems are *Prometheus*, ii. 3, 50, "*See'st thou* shapes within the mist" (Zupitza for "*I see thin* shapes"); *ib.* iv. 4, 242, "Purple and azure, white *and* green, and golden" (*and* inserted by Rossetti); *Prince Athanase*, 150 sqq. "the rugged path | Where she once saw that horseman toil, with brief | And *blighting* hope, who with the news of death | Struck body and soul as with a mortal blight" (*blighting*, condemned by Rossetti, is cancelled in the Bodleian MS.).

It is a weakness of conservative critics to extol interpretation (or exegesis) at the expense of emendation. Some have even ventured to say that the successful defence of a passage in a text is a greater service than its successful correction. This is not true. The service to the text is the same, what was previously dark being now made clear. But the emendation deserves the higher praise as being in most instances the more difficult achievement. The fault of the opposite school, on the other hand, is to disparage interpretation and to regard correction as the proper field of a scholar and gentleman. This bias is reflected in the maxim that "correction should precede interpretation," which is no more than a half-truth. For emendation must inevitably fail unless it express the meaning which the proper interpretation of the passage has shown to be required. Further, a corrector may propose the right word with the wrong meaning. Yet the custom is to give the credit of the emendation to him, and not to a successor who has seen what the right sense was and that this was the only word to express it, whereas the first scholar blundered once if not twice, first assigning the wrong sense to the passage and then selecting what (in most cases) would be the wrong word to express it. The proper course would be not to mention the first conjecturer or to mention him only for his error.

One of the most vexed questions of textual criticism, and one which divides scholars more perhaps than any other, is the question to what extent admitted imperfections and inconsistencies may properly be left in a text as due to the default of an author rather than of a scribe or compositor. No universal rule is here attainable. Each case must be considered on its merits; and the critic's procedure must of necessity be "eclectic"—an epithet often used with a tinge of reproach, the ground for which it is not easy to discover. Two general considerations may be indicated. If the autograph of a work is not accessible, there is no means of distinguishing between the involuntary errors of a scribe and the involuntary errors—"slips of pen"—of an author. For the latter are in fact only scribe's mistakes, the author being his own amanuensis. To take the example given under *Confusions of Words* above, *loin* for *lion* in *Cranford* is probably a printer's error, but it is conceivable that it is due to a deflexion of the authoress's mind or pen through the accidental proximity of the "mutton chop."

Passing over this class we come to one about which there may frequently be serious doubt. What is clearly erroneous or faulty may as clearly be intended, and therefore *not* to be removed by the critic. In Chaucer's "Miller's Tale" (3451, 3457) *astromie* is used for *astronomie*, and *Noë* and *Noël* (Christmas) confused, "Nowélis flood" (3451, 3457), because the speaker is an illiterate carpenter. In the Prologue to the "Parson's Tale" (10) there is, on the other hand, a mistake of Chaucer's own, which no judicious critic would think of removing, the constellation Libra being said to be "*the moon's* exaltation" when it should be *Saturn's*. But this error in an astrological detail would not warrant us in assigning to the poet the blunder about Jacob and Laban in the same tale (see above). Much depends on the precision with which an error can be corrected: wherever there are more plausible ways than one of doing this, the faulty reading must be allowed to remain. Collateral as well as direct evidence must be obtained. If there are a number of instances where there is faultiness which is hard to remove, it is probable that the evil lies too deep for emendation. The author's own carelessness may be to blame, or, as in the case of Virgil and Lucan, he may not have been allowed to put the finishing touches to his work.

Certain lapses from grammatical correctness and metrical regularity that we find in the poems of Shelley are undoubtedly due to the author, though the number of these has been reduced (as Mr Buxton Forman has pointed out) with our improved knowledge of the sources of the text. Amongst such lapses we may instance *Prince Athanase* (287), "The shadow of thy moving wings *imbue* | Its deserts and its mountains"; "To a Skylark" (80), "Thou lovest—but ne'er *knew* love's sad satiety." The solecism in the Preface to the *Adonais*, "My known repugnance to the narrow principles of taste on which several of his earlier compositions were modelled *prove* at least that I am an impartial judge," would probably have been corrected by the poet if his attention had been called to it; but the two first ones, with others, cannot be thus regarded. We may detect occasional laxity also in his handling of his verse. Lines are left unrhymed: *e.g., Julian and Maddalo* (211); *Rosalind and Helen* (366). Or the same word is used in place of another rhyming word: *Revolt of Islam* (3573 and 3576, 3829 and 3831). In the *Daemon of the World* (341–2), Shelley himself cancelled a metrical reading for one that makes the verse a syllable too short. It is in this department of criticism that the personal equation has the freest play, and hence the natural adherents of either school of critics should be specially on their guard against their school's peculiar bias.

The part which conjectural emendation should play must obviously be very different in different texts. In the New Testament, for example, this part is very small indeed, though it cannot be altogether excluded. Colossians ii. 18 is corrupt as it appears; but the adoption of a correction recommended by Bishop Lightfoot and Dr C. Taylor will restore it to sense.

It has been maintained that emendation (being guessing) is no part of textual criticism at all, though judgment upon emendation is. The position approaches to paradox and is not likely to be generally accepted. But it does contain an element of truth and indicates a well-founded reproach against the majority of those who practise conjecture. Nothing has discredited emendation as a means of improving texts more than the want of method, common care and research, which those addicted to it show. Some of the most distinguished scholars have offended worst. The *Milton* of Bentley, England's greatest critic, is a by-word. To examine all the causes which may vitiate emendations would mean writing a treatise upon human frailty. But the reason why the vast majority of them fail is that the vast majority of them should never have been made at all. Their proposers do not take even elementary precautions to be right. An inquirer who examines the stars with a shilling telescope is not likely to make observations of value, and even a trained astronomer has to allow for his "personal equation"—a point to which even a finished critic rarely attends. Successful emendation requires a rare union of qualifications—insight, prudence, patience and familiarity with the author emended and the conditions of his text. If any of these is absent, the work is apt to be wasted.

Authority, as already hinted, has properly no place in textual criticism. For his facts a textual critic may, and often must, be beholden to others: but never for his opinions. It adds nothing to the evidence for a reading that it has been approved by a Lachmann or a Madvig or rejected by a Stoeber or a Carutti: and an appeal to names on any such question confuses issues and deters inquiry. But inasmuch as there are many persons, including most makers of school editions, who prudently and modestly desire a better road to truth than their own investigations can discover and think thus to find it, it will not be amiss to observe on the one hand that the concurrence of a succession of editors in a reading is no proof and often no presumption either that their agreement is independent or that their reading is right; and on the other that, though independence may generally be granted to coinciding emendations of different scholars, yet from the general constitution of the human mind it is likely that not a few of these will be coincidences in error rather than in truth.

One of the marks of a great textual critic is his attention to details. He will not consider his work upon the text complete until he has made it, as far as he can, such as the author would approve in every particular. Accordingly he will restore the spelling of the author if that can be ascertained: he will not accept the corruptions which have been introduced into it by copyists or printers, even though these may not affect its sense, nor will he modernize it so as to bring it into harmony with that of a later and to him a more familiar age. Thus, to take an example, he will not print a critical text of Plautus with two letters (Y and Z) which were no part of the Latin alphabet in the age of that comedian; still less will he introduce into Latin texts distinctions, such as *i*, *j* and *u*, *v*, which were not used till long after the middle ages.

As time goes on, textual criticism will have less and less to do. In the old texts its work will have been performed so far as it is performable. What is left will be an obstinate remainder of difficulties, for which there is no solution or only too many. In the newer texts, on the other hand, as experience has already shown, it will have from the outset but a very contracted field.

(J. P. P.)

TEZPUR, or TEJPUR, a town of British India, the administrative headquarters of Darrang district, Eastern Bengal and Assam, on the right bank of the Brahmaputra. Pop. (1901) 5047. It is the centre of a flourishing tea industry, and contains many houses of English residents. Communications are maintained by river steamer, while a light railway runs northward through the tea-growing tract.

THAʽĀLIBĪ [Abu Manṣūr ʽAbd ul-Malik ibn Mahommed ibn Isma'īl uth-Thaʽālibī] (961–1038), Arabian philologist, was born in Nīshāpūr, and is said to have been at one time a furrier. Although he wrote prose and verse of his own, he was most famous for his anthologies and collections of epigrams. Like many other Arabian writers, he does not always distinguish between his own and other people's work. Of the twenty-nine works known to have been written by him, the most famous is his *Kitāb Yatīmat ud-Dahr*, on the poets of his own and earlier times, arranged according to the countries of the poets, and containing valuable extracts (published at Damascus, 4 vols., 1887). Another of his works, the *Kitāb Fiqh ul-Lugha*, is lexicographical, the words being arranged in classes. It has been published at Paris (1861), Cairo (1867), and Beirūt (1885, incomplete).

For his other works see C. Brockelmann's *Geschichte der Arabischen Litteratur*, vol. i. (Weimar, 1898), pp. 284–86. (G. W. T.)

THACKERAY, WILLIAM MAKEPEACE (1811–1863), English novelist, only son of Richmond and Anne Thackeray (whose maiden name was Becher), was born at Calcutta on the 18th of July 1811. Both his father and his grandfather (W. R. Thackeray) had been Indian civil servants. His mother was only nineteen at the date of his birth, was left a widow in 1816, and afterwards married Major Henry Carmichael Smyth. Young Thackeray was brought home to England from India as a child, and was sent to private schools, first in Hampshire and then at Chiswick. In 1822 he was transferred to Charterhouse, at that time still on its ancient site near Smithfield. Anthony Trollope, in his book on Thackeray in the "English Men of Letters" series, quotes a letter written to him about Thackeray's schooldays by George Stovin Venables. "He came to school young," Venables wrote, "a pretty, gentle, and rather timid boy." This accords with the fact that all through Thackeray's writings the student may find traces of the sensitiveness which often belongs to the creative mind, and which, in the boy who does not understand its meaning and its possible power, is apt to assume the guise of a shrinking disposition. To this very matter Venables tersely referred in a later passage of the letter quoted by Trollope: "When I knew him better, in later years, I thought I could recognize the sensitive nature which he had as a boy." Another illustration of this idiosyncrasy is found in the statement, which will be recognized as exact by all readers of Thackeray, that "his change of retrospective feeling about his schooldays was very characteristic. In his earlier books he always spoke of the Charterhouse as Slaughter House and Smithfield. As he became famous and prosperous his memory softened, and Slaughter House was changed into Grey Friars, where Colonel Newcome ended his life." Even in the earlier references the bitterness which has often been so falsely read into Thackeray is not to be found. In "Mr and Mrs Frank Berry" (*Men's Wives*) there is a description of a fight at Slaughter House following on an incident almost identical with that used in *Vanity Fair* for the fight between Dobbin and Cuff. In both cases the brutality of school life, as it then was, is very fully recognized and described, but not to the exclusion of the chivalry which may go alongside with it. In the first chapter of "Mr and Mrs Frank Berry," Berry himself and old Hawkins both have a touch of the heroic, and in this story the bully whom Berry gallantly challenges is completely defeated, and one hears no more of him. In *Vanity Fair* Cuff the swaggerer is defeated as completely as is Berry's opponent, but regains his popularity by one well-timed stroke of magnanimity, and afterwards shows the truest kindness to his conqueror. Thackeray left Charterhouse in 1828 to join his mother and her husband at Larkbeare in Devonshire, near Ottery St Mary. Ottery St Mary is the "Clavering St Mary," as Exeter and Sidmouth are respectively the "Chatteris" and "Baymouth" of *Pendennis*.

In February 1829 Thackeray went to Trinity College, Cambridge, and in that year contributed some engaging lines on "Timbuctoo," the subject for the Prize Poem (the prize for which was won in that year by Tennyson), to a little paper called *The Snob*, a title which Thackeray afterwards utilized in the famous *Book of Snobs*. The first stanza has become tolerably well known, but is worth quoting as an early instance of the direct comic force afterwards employed by the author in verse and prose burlesques:—

> "In Africa—a quarter of the world—
> Men's skins are black; their hair is crisp and curled;
> And somewhere there, unknown to public view,
> A mighty city lies, called Timbuctoo."

One other passage at least in *The Snob*, in the form of a skit on a paragraph of fashionable intelligence, seems to bear traces of Thackeray's handiwork. At Cambridge, James Spedding, Monckton Milnes (Lord Houghton), Edward FitzGerald, W. H. Thompson (afterwards Master of Trinity), and others who made their mark in later life, were among his friends. In 1830 he left Cambridge without taking a degree, and went to Weimar and to Paris. His visit to Weimar bore fruit in the keen sketches of life at a small German court which appear in *Fitz-Boodle's Confessions* and in *Vanity Fair*. In G. H. Lewes's *Life of Goethe* is a letter containing Thackeray's impressions of the German poet. On his return to England in 1831 he entered the Middle Temple. He did not care to pursue the study of the law, but he found in his experience of the Temple the material for some capital scenes in *Pendennis*. In 1832 he came of age, and inherited a sum which, according to Trollope, "seems to have amounted to about five hundred a year." The money was soon lost—some in an Indian bank, some at play and some in two newspapers, *The National Standard* (with a long sub-title) and *The Constitutional*. In *Lovel the Widower* these two papers are indicated under one name as *The Museum*, in connexion with which our friends Honeyman and Sherrick of *The Newcomes* are briefly brought in. Thackeray's adventures and losses at play were utilized in his literary work on three occasions, in "A Caution to Travellers" (*The Paris Sketch-Book*), in the first of the Deuceace narrations (*The Memoirs of Mr C. J. Yellowplush*), and in *Pendennis*, vol. ii. chap. v., in a story (wherein Deuceace reappears) told to Captain Strong by "Colonel Altamont." As to Deuceace, Sir Theodore Martin has related how once in the playrooms at Spa Thackeray called his attention to a certain man and said presently, "That was the original of my Deuceace."

In 1834 or at the end of 1833 Thackeray established himself in Paris in order to study art seriously. He had, like Clive in *The Newcomes*, shown talent as a caricaturist from his early boyhood. His gift proved of great value to him in illustrating much of his own literary work in a fashion which, despite all incorrectness of draughtsmanship, conveyed vivid suggestions that could not have been so well given by anyone but himself. Perhaps his pencil was at its best technically in such fantastic work as is found constantly in the initial letters which he frequently used for chapters in his various kinds of work, and in those drawings made for the amusement of some child friends which were the origin of *The Rose and the Ring*.

In 1836 Thackeray married Isabella, daughter of Colonel Matthew Shawe. There were three daughters born of the marriage, one dying in infancy. The eldest daughter, Anne Isabella (b. 1837), married in 1877 Mr Richmond Ritchie, of the India Office, who in 1907 was created a K.C.B. She inherited literary talent from her father and wrote several charming works of fiction, notably *Miss Angel* (1875), and subsequently edited Thackeray's works and published some volumes of criticism and reminiscences. The younger daughter, Harriet Marian (b. 1840), married (Sir) Leslie Stephen in 1867 and died in 1875. Thackeray's own family life was early broken, for Mrs Thackeray, to quote Trollope, "became ill and her mind failed her," in 1840, and he "became as it were a widower to the end of his days"; Mrs Thackeray did not die till 1892.

In 1837 Thackeray came to London, worked at various kinds of journalism, and became a regular contributor to *Fraser's Magazine*. In this in 1841 appeared *The History of Mr Samuel Titmarsh and the Great Hoggarty Diamond*, a work filled with instances of the wit, humour, satire, pathos, which found a more ordered if not a fresher expression in his later and longer works. For freshness, indeed, and for a fine perception which enables the author to perform among other feats that of keeping up throughout the story the curious simplicity of its supposed narrator's character, *The Great Hoggarty Diamond* can scarcely be surpassed. The characters, from Lady Drum, Lady Fanny Rakes, Lady Jane and Edmund Preston, to Brough, Mrs and Miss Brough, Mrs Roundhand, Gus Hoskins, and, by no means least, Samuel Titmarsh's aunt, Mrs Hoggarty, with her store of "Rosolio," are full of life; the book is crammed with honest fun; and for pure pathos, the death of the child, and the meeting of the husband and wife over the empty cradle, stands, if not alone in its own line, at least in the company of very few such scenes in English fiction. *The Great Hoggarty Diamond*, oddly enough, met with the fate that afterwards befell one of Lever's best stories which appeared in a periodical week by week—it had to be cut short at the bidding of the editor. In 1840 came out *The Paris Sketch-Book*, much of which had been written and published at an earlier date. The book contains among other things some curious divagations in criticism, along with some really fine critical work, and a very powerful sketch called "A Gambler's Death." In 1838 Thackeray had begun, in *Fraser*, *The Yellowplush Papers*, with their strange touches of humour, satire, tragedy (in one scene, the closing one of the history of Mr Deuceace), and their sublimation of fantastic bad spelling (M'Arony for macaroni is one of the typical touches of this); and this was followed by *Catherine*, a strong story, and too disagreeable perhaps for its purpose, founded closely on the actual career of a criminal named Catherine Hayes, and intended to counteract the then growing practice of making ruffians and harlots prominent characters in fiction. Now, when *Pendennis* was coming out in serial form (1850), Miss Catherine Hayes, a singer of Irish birth and a famous *prima donna* (Sims Reeves described her as "the sweetest Lucia [di Lammermoor] he had ever sung with") was much before the public. A reflective passage in a number of *Pendennis* referred indignantly and scornfully to Catherine Hayes, the criminal of old time, coupling her name with that of a then recently notorious murderer. It would appear that Thackeray had for the moment, oddly enough, omitted to think of Miss Catherine Hayes, the justly famed soprano, while certain Irish folk were obviously ignorant or oblivious of the history of Catherine Hayes the murderess. Anyhow, there was a great outcry in the Irish press, and Thackeray was beset by private letters of indignation from enthusiastic compatriots of the *prima donna*. In deference to susceptibilities innocently outraged Thackeray afterwards suppressed the passage which had given offence. The thing is worth mention if only because it explains the initial letter drawn by Thackeray for chap. xv., vol. ii., of *Pendennis*. The drawing is in itself highly comic, but must seem quite meaningless without the key.

There soon followed *Fitz-Boodle's Confessions and Professions*, including the series *Men's Wives*, already mentioned; and slightly before these, the *Shabby Genteel Story*, a work interrupted by Thackeray's domestic affliction and afterwards republished as an introduction to *The Adventures of Philip*, which took up the course of the original story many years after the supposed date of its catastrophe. In 1843 also came out the *Irish Sketch-Book*, and in 1844 appeared the account of the journey *From Cornhill to Grand Cairo*, in which was included the excellent poem of "The White Squall." In 1844 there began in *Fraser* the *Memoirs of Barry Lyndon*, called in the magazine "The Luck of Barry Lyndon, a Romance of the Last Century." "Barry Lyndon" has, with a very great difference in treatment, some resemblance to Smollett's "Ferdinand, Count Fathom"—the hero, that is to say, is or becomes a most intolerable scoundrel, who is magnificently unconscious of his own iniquity. The form and pressure of the time depicted are caught with striking verisimilitude, and in the boyish career of Barry Lyndon there are fine touches of a wild chivalry, simplicity, generosity, which mingle naturally with those worse qualities that, under the influence of abominable training, afterwards corrupt his whole mind and career. The man is so infatuated with and so blind to his own roguery, he has so much dash and daring, and is on occasions so infamously treated, that it is not easy to look upon him as an entirely detestable villain until, towards the end of his course, he becomes wholly lost in brutish debauchery and cruelty. His latter career is founded on that of Andrew Robinson Stoney Bowes, who married the widow of John, 9th earl of Strathmore. There is also no doubt a touch of Casanova in Barry Lyndon's character. Thackeray became a contributor to *Punch* within the first year of its existence. John Leech, who was one of the earliest contributors, had been at Charterhouse with Thackeray and the two men were friends through life. Thackeray's first series contributed to *Punch* did not attain or indeed deserve signal success. He made his first hit with *Jeames's Diary*, begun in November 1845, and may be said to have established his reputation by the *Snob Papers* (1846), now better known as *The Book of Snobs*. These, besides greatly improving Thackeray's position, provoked much discussion of various kinds. Thackeray himself was naturally accused of being a snob. To this charge he had partly given an anticipatory answer (in the third chapter) in the statement that "it is impossible, in our condition of society, *not* to be sometimes a Snob," and in giving the name of "Mr Snob" to the supposed historian of snobs throughout the series. Thackeray's connexion with *Punch* came practically to an end in 1851. The severance was due partly to differences in political opinion. His personal relations with the staff of *Punch* always remained cordial. Special mention may be made of one other contribution of his to the paper, "*Punch's Prize Novelists*," containing some brilliant parodies of Edward Lytton Bulwer, Lever, Benjamin Disraeli (in "Codlingsby," perhaps the most perfect of the series), and others. Among minor but admirable works of the same period are found *A Legend of the Rhine* (a burlesque of the great Dumas's *Othon l'Archer*), brought out in George Cruikshank's *Table Book*, edited by Gilbert Abbott À Beckett, *Cox's Diary* (on which has been founded a well-known Dutch comedy, *Janus Tulp*), and *The Fatal Boots*. This is the most fitting moment for naming also *Rebecca and Rowena*, which towers, not only over Thackeray's other burlesques, excellent as they are, but over every other burlesque of the kind ever written. Its taste, its wit, its pathos, its humour, are unmatchable; and it contains some of the best songs of a particular kind ever written—songs rivalled only by Peacock's best of the same sort. In 1846 was published, by Messrs Bradbury and Evans, the first of twenty-four numbers of *Vanity Fair*, the work which first placed Thackeray in his proper position before the public as a novelist and writer of the first rank. It was completed in 1848, when Thackeray was thirty-seven years old; and in the same year Abraham Hayward paid a tribute to the author's powers in the *Edinburgh Review*. It is probable that on *Vanity Fair* has been largely based the foolish cry, now heard less and less frequently, about Thackeray's cynicism, a cry which he himself, with his keen knowledge of men, foresaw and provided against, amply enough as one might have thought, at the end of the eighth chapter, in a passage which is perhaps the best commentary ever written on the author's method. He has explained how he wishes to describe men and women as they actually are, good, bad and indifferent, and to claim a privilege.

"Occasionally to step down from the platform, and talk about them; if they are good and kindly, to love and shake them by the hand; if they are silly, to laugh at them confidentially in the reader's sleeve; if they are wicked and heartless, to abuse them in the strongest terms politeness admits of. Otherwise you might fancy it was I who was sneering at the practice of devotion, which

Miss Sharp finds so ridiculous; that it was I who laughed good-humouredly at the railing old Silenus of a baronet—whereas the laughter comes from one who has no reverence except for prosperity, and no eye for anything beyond success. Such people there are living and flourishing in the world—Faithless, Hopeless, Charityless: let us have at them, dear friends, with might and main. Some there are, and very successful too, mere quacks and fools; and it was to combat and expose such as those, no doubt, that laughter was made."

As to another accusation which was brought against the book when it first came out, that the colours were laid on too thick, in the sense that the villains were too villainous, the good people too goody-goody, the best and completest answer to that can be found by anyone who chooses to read the work with care. Osborne is, and is meant to be, a poor enough creature, but he is an eminently human being, and one whose poorness of character is developed as he allows bad influences to tell upon his vanity and folly. The good in him is fully recognized, and comes out in the beautiful passage describing his farewell to Amelia on the eve of Waterloo, in which passage may be also found a sufficient enough answer to the statement that Amelia is absolutely insipid and uninteresting. So with the companion picture of Rawdon Crawley's farewell to Becky Sharp: who that reads it can resist sympathy, in spite of Rawdon's vices and shady shifts for a living, with his simple bravery and devotion to his wife? As for Becky, a character that has since been imitated a host of times, there is certainly not much to be said in her defence. We know of her, to be sure, that she thought she would have found it easy to be good if she had been rich, and we know also what happened when Rawdon, released without her knowledge from a spunging-house, surprised her alone with and singing to Lord Steyne in the house in Mayfair. After a gross insult from Steyne, "Rawdon Crawley, springing out, seized him by the neckcloth, until Steyne, almost strangled, writhed and bent under his arm. 'You lie, you dog,' said Rawdon; 'you lie, you coward and villain!' And he struck the peer twice over the face with his open hand, and flung him bleeding to the ground. It was all done before Rebecca could interpose. She stood there trembling before him. She admired her husband, strong, brave, and victorious." This admiration is, as Thackeray himself thought it, the capital touch in a scene which is as powerful as any Thackeray ever wrote—as powerful, indeed, as any in English fiction. Its full merit, it may be noted in passing, has been curiously accented by an imitation of it in Alphonse Daudet's *Fromont Jeune et Risler Aîné*. As to the extent of the miserable Becky's guilt in the Steyne matter, Thackeray leaves it practically open to the reader to form what conclusion he will. There is, it should be added, a distinct touch of good in Becky's conduct to Amelia at Ostend in the last chapter of the book, and those who think that too little punishment is meted out to the brilliant adventuress in the end may remember this to her credit. It is supreme art in the treatment of her character that makes the reader understand and feel her attractiveness, though he knows her extraordinarily evil qualities; and in this no writer subsequent to Thackeray who has tried to depict one of the genus Becky Sharp has even faintly succeeded. Among the minor characters there is not one—and this is not always the case even with Thackeray's chief figures—who is incompletely or inconsistently depicted; and no one who wishes fully to understand and appreciate the book can afford to miss a word of it.

Vanity Fair was followed by *Pendennis*, *Esmond* and *The Newcomes*, which appeared respectively in 1850, 1852 and 1854. It might be more easy to pick holes critically in *Pendennis* than in *Vanity Fair*. Pendennis himself, after his boyish passion and university escapades, has disagreeable touches of flabbiness and worldliness; and the important episode of his relations with Fanny Bolton, which Thackeray could never have treated otherwise than delicately, is so lightly and tersely handled that it is a little vague even to those who read between the lines. It can hardly be said that there is adequate preparation for the final announcement that those relations have been innocent, and one can hardly see why it should have been so long delayed. This does not, of course, affect the value of the book as a picture of middle- and upper-class life of the time, the time when Vauxhall still existed, and the haunt for suppers and songs which Thackeray in this book called the Back Kitchen, and it is a picture filled with striking figures. In some of these, notably in that of Foker, Thackeray went, it is supposed, very close to actual life for his material, and in that particular case with a most agreeable result. As for the two "umbrae" of Lord Steyne, it is difficult to believe that they were intended as caricatures of two well-known persons. If they were, for once Thackeray's hand forgot its cunning. Here, as in the case of Amelia Sedley (*Vanity Fair*), the heroine has been thought a little insipid; and there may be good ground for finding Laura Pendennis dull, though she has a spirit of her own. In later books she becomes, what Thackeray's people very seldom are, a tiresome as well as an uninviting person. Costigan is unique, and so is Major Pendennis, a type which, allowing for differences of periods and manners, will exist as long as society exists, and which has been seized and depicted by Thackeray as by no other novelist. The Major's two encounters, from both of which he comes out victorious, one with Costigan in the first, the other with Morgan in the second volume, are true touches of genius. In opposition to the worldliness of the Major, with which Pendennis does not escape being tainted, we have Warrington, whose nobility of nature has come unscathed through a severe trial, and who, a thorough gentleman if a rough one, is really the guardian of Pendennis's career. There is, it should be noted, a characteristic and acknowledged confusion in the plot of *Pendennis*, which will not spoil any intelligent reader's pleasure.

Probably most readers of *The Newcomes* (1854) to whom the book is mentioned think first of the fine, chivalrous and simple figure of Colonel Newcome, who stands out in the relief of almost ideal beauty of character against the crowd of more or less imperfect and more or less base personages who move through the novel. At the same time, to say, as has been said, that this book "is full of satire from the first to the last page" is to convey an impression which is by no means just. There is plenty of kindliness in the treatment of the young men who, like Clive Newcome himself and Lord Kew, possess no very shining virtue beyond that of being honourable gentlemen; in the character of J. J. Ridley there is much tenderness and pathos, and no one can help liking the Bohemian "F. B.," and looking tolerantly on his failings. It may be that there is too close an insistence on the fiendish temper of Mrs Mackenzie and on the sufferings she inflicts on the colonel; but it must be remembered that this heightens the singular pathos of the closing scenes of the colonel's life. It has seemed convenient to take *The Newcomes* after *Pendennis*, because Pendennis and his wife reappear in this book as in *The Adventures of Philip*; but *Esmond* (1852) was written and published before *The Newcomes*. To some students *Esmond* seems and will seem Thackeray's capital work. It has not been rivalled as a romance reproducing with unfailing interest and accuracy the figures, manners and phrases of a past time, and it is full of beautiful touches of character. But Beatrix, upon whom so much hinges, is an unpleasing character, although one understands fully why men were captivated by her insolent beauty and brilliancy; and there is some truth in Thackeray's own saying, that "Esmond was a prig." Apart from this, the story is, like the illusion of a past time in the narrative, so complete in all its details, so harmoniously worked out, that there is little room for criticism. As to Esmond's marriage with the lady whom he has served and loved as a boy, that is a matter for individual judgment. Beatrix, it has been indicated above, is wonderfully drawn: and not the least wonderful thing about her is her reappearance as the jaded, battered, worldly, not altogether unkindly, Baroness in *The Virginians*. It was just what Beatrix must have come to, and her decline is handled with the lightest and finest touch.

In 1851 Thackeray had written *The English Humourists of the Eighteenth Century*, delivered as a series of lectures at Willis's

Rooms in the same year, and re-delivered in the United States in 1852 and 1853, as was afterwards the series called *The Four Georges*. Both sets were written for the purpose of lecturing. In 1854 was published a most delightful burlesque, *The Rose and the Ring*, whereof the origin has already been mentioned. In 1857 Thackeray stood unsuccessfully as a parliamentary candidate for Oxford against Mr Cardwell, and in the same year appeared the first number of *The Virginians*, a sequel to *Esmond*. This is a most unequal work—inferior, as sequels are apt to be, to *Esmond* as an historical romance, less compact and coherent, prone to divagation and desultoriness, yet charming enough in its lifelikeness, in the wit and wisdom of its reflexions, and, as has been said, in its portrait of Beatrix grown old. The last number of *The Virginians* came out in 1859, and in the same year Thackeray undertook the editorship of the *Cornhill Magazine*. This was a task which, as readers of his *Roundabout Paper* "Thorns in the Cushion" will remember, the kindliness and sensitiveness of his disposition made irksome to him, and he resigned the editorship in April 1862, though he continued to write for the magazine until he died. In the *Cornhill* appeared from his pen *Lovel the Widower*, previously written, with different names for some of the personages, in dramatic form; *The Adventures of Philip* (1861–62); the *Roundabout Papers;* and (1860–63) the story, unhappily never finished, called *Denis Duval*. *Lovel the Widower*, changed from the dramatic to the narrative form, remains a piece of high comedy in which the characters are indicated rather than fully worked out, with a bold and practised touch. The *Roundabout Papers*, a small storehouse of some of Thackeray's best qualities as an essayist, came out in the *Cornhill Magazine* simultaneously with *Lovel the Widower* and with *The Adventures of Philip*. Among these papers is one differing in form from the rest, called "The Notch on the Axe—a Story à la Mode." It is an almost perfect specimen of the author's genius for burlesque story-telling; but it contains an odd instance, which a careful reader will not fail to discover, of that odd habit of inaccuracy of which Thackeray himself was conscious. *The Adventures of Philip* is, as has been before said, in the nature of a sequel to or a completion of *A Shabby Genteel Story*. As with the other direct sequel, it is a work of great inequality. It contains scenes of humour, pathos, satire, which rank with Thackeray's best work; some old friends from others of the novels make brief but pleasant reappearances in its pages; there are fine sketches of journalistic, artistic and diplomatic life, and the scene from the last-named in Paris is inimitable. The Little Sister is altogether delightful; the Twysden family are terribly true and vastly diverting; the minor characters, among whom old Ridley, "J. J.'s" father, should be mentioned, are wonderfully hit off; nor did Thackeray ever write a better scene than that of the quarrel between Bunch, Baynes and M'Whirter in the Paris pension. Philip himself is impossible; one cannot say that the character is ill-drawn—it is not drawn at all. It is an entirely different personage in different chapters; and it has here and there a very unpleasant touch which may perhaps have come of rapid writing. Yet so admirable are many parts of the book that *Philip* cannot be left out of the list of Thackeray's most considerable works. *Denis Duval*, which reached only three numbers, promised to be a first-rate work, more or less in the *Esmond* manner. The author died while it was in progress, on the day before Christmas day 1863. He was buried in Kensal Green, and a bust by Marochetti was put up to his memory in Westminster Abbey.

Little has yet been said of Thackeray's performances in poetry. They formed a small but not the least significant part of his life's work. The grace and the apparent spontaneity of his versification are beyond question. Some of the more serious efforts, such as "The Chronicle of the Drum" (1841), are full of power, and instinct with true poetic feeling. Both the half-humorous, half-pathetic ballads and the wholly extravagant ones must be classed with the best work in that kind; and the translations from Béranger are as good as verse translations can be. Thackeray had the true poetic instinct, and proved it by writing poetry which equalled his prose in grace and feeling.

There can be little doubt that Thackeray will always be ranked among the foremost English writers of fiction, or that his more infrequent work as essayist and poet will go hand in hand with his wider achievements as a novelist. Many attempts have been made at many times to institute a comparison between Thackeray and Dickens as novelists. In truth it would be as much to the purpose, to borrow a homely metaphor, to compare chalk with cheese. The two authors were so radically different in their purviews, in their modes of thought, in their methods of expression, that critical comparison between them is of its nature absolutely unprofitable. It is better to recognize simply that the two novelists stood, each in his own way, distinctly above even their most distinguished contemporaries. As to preference, that is a matter with which criticism has nothing, and individual inclination has everything, to do.

The books of reference that can be best commended to the student of Thackeray's life and works are Merivale and Marzials' *Life of Thackeray* (1891); R. H. Shepherd, *Bibliography of Thackeray* (1880); C. P. Johnson, *The Early Writings of Thackeray* (1888); Charles Whibley's *Thackeray* (1905), a critical commentary; the edition of Thackeray's Works with biographical introductions (1897–1900), by his daughter, Lady Ritchie; the *Life of Thackeray* ("English Men of Letters Series," 1899) by Anthony Trollope. It is curious that Trollope showed in his own Autobiography far more appreciation of Thackeray's great qualities than is apparent in the formal Life. (W. H. P.)

THAÏS, a Greek courtesan, who lived during the time of Alexander the Great. She accompanied him on his Asiatic campaign, and is chiefly known from the story which represents her as having persuaded the conqueror to set fire to the city of Persepolis. This anecdote forms the subject of Dryden's *Ode to Saint Cecilia's Day*. But its authenticity is doubtful, since it is based upon the authority of Cleitarchus, one of the least trustworthy of the historians of Alexander. Thaïs subsequently became the wife of Ptolemy Lagus, king of Egypt. Numerous anecdotes and witticisms attributed to her will be found in Athenaeus.

See Diod. Sic. xvii. 72; Plutarch, *Alexander*, 38; Athenaeus xiii. 576, 585; Quintus Curtius v. 7.

THALBERG, SIGISMOND (1812–1871), German pianist and composer, was born at Geneva in 1812 (May the 5th or January the 7th). In 1822 he was taken to Vienna, where, under the watchful care of Count Dietrichstein, his education was completed. He made his first appearance as a pianist at Prince Metternich's in 1826, and published his first composition—a *Fantasia on Airs from "Euryanthe"*—in 1828, but it was not until 1830 that he was first fairly introduced to the public, with such brilliant success that from that time forward his only rival was Liszt (*q.v.*). In 1834 he was appointed "kammervirtuos" to the emperor of Austria. He first appeared in Paris in 1837; and in 1838 he went to England, astonishing his hearers with the novel effects produced in his *Variations on God Save the Queen*, while he charmed them with his delicate touch and the purity of his expression. Thenceforward his career was a succession of triumphs. In order to disprove the popular idea that he could execute no music but his own, he played Beethoven's *Concerto in C minor* (Op. 37) at the London Wednesday Concerts, held in 1846–47 at Exeter Hall, with a keen intelligence which proved his power of interpreting the works of the great masters to be at least on a level with his wonderful *technique*. Besides his pianoforte compositions, which are almost innumerable, Thalberg produced two operas—*Cristina*, which proved a complete failure, and *Florinda*, which fared but little better at Her Majesty's Theatre in 1851. He played in London for the last time in 1863, and afterwards retired to his estate near Naples. He died at Naples on the 27th of April 1871.

THALE, a town of Germany, in the Prussian province of Saxony, charmingly situated under the northern declivity of the Harz Mountains, 8 m. by rail S.W. of Quedlinburg, at the entrance to the romantic gorge of the Bode, and in the immediate vicinity of the Rosstrappe, the Hexentanzplatz and other notable points in the Harz. Pop. (1905) 13,194. It is largely frequented as a summer resort and for its saline springs. It is also a brisk manufacturing centre, its chief products being enamelled goods, iron-ware and machinery.

THALES OF MILETUS (640–546 B.C.), Greek physical philosopher, son of Examyus and Cleobuline, is universally recognized as the founder of Greek geometry, astronomy and philosophy. He is said by Herodotus and others to have been of Phoenician extraction, but the more common account (see DIOGENES LAËRTIUS) is that he was a native Milesian of noble birth. Zeller thinks that his ancestors belonged to the Cadmean tribe in Boeotia, who were intermingled with the Ionians of Asia Minor, and thus reconciles the conflicting statements. The nationality of Thales is certainly Greek and not Phoenician. The high estimation in which he was held by his contemporaries is shown by the place he occupied as chief of the seven "wise men" of Greece; and in later times amongst the ancients his fame was quite remarkable. It is well known that this name (σοφός) was given on account of practical ability; and in accordance with this we find that Thales had been occupied with civil affairs, and indeed several instances of his political sagacity have been handed down. Of these the most remarkable is the advice, praised by Herodotus, which he gave to his fellow-countrymen "before Ionia was ruined"—"that the Ionians should constitute one general council in Teos, as the most central of the twelve cities, and that the remaining cities should nevertheless be governed as independent states" (Herod. i. 170). It is probable, however, that in the case of Thales the appellation "wise man," which was given to him and to the other six in the archonship of Damasius (586 B.C.),[1] was conferred on him not only on account of his political sagacity, but also for his scientific eminence (Plut. *Solon*, c. 3). To about the same time must be referred his celebrated prediction of the eclipse of the sun, which took place on the 28th of May 585 B.C. This event, which was of the highest importance, has given rise to much discussion. The account of it as given by Herodotus (i. 74) contains two statements:—(1) the fact that the eclipse did actually take place during a battle between the Medes and the Lydians, that it was a total eclipse (Herodotus calls it a "night battle"), that it caused a cessation of hostilities and led to a lasting peace between the contending nations; (2) that Thales had foretold the eclipse to the Ionians, and fixed the year in which it actually did take place. Various dates—ranging from 625 B.C. to 583 B.C.—have been assigned by different chronologists to this eclipse; but, since the investigations of Airy,[2] Hind,[3] and Zech,[4] the date determined by them (May 28, 585 B.C.) has been generally accepted (for later authorities see ECLIPSE and ASTRONOMY). This date agrees nearly with that given by Pliny (*H. N.* ii. 12). The second part of the statement of Herodotus—the reality of the prediction by Thales—has been frequently called in question, chiefly on the ground that, in order to predict a solar eclipse with any chance of success, one should have the command of certain astronomical facts which were not known until the 3rd century B.C., and then merely approximately, and only employed with that object in the following century by Hipparchus. The question, however, is not whether Thales could predict the eclipse of the sun with any chance of success—much less whether he could state beforehand at what places the eclipse would be visible, as some have erroneously supposed, and which of course would have been quite impossible for him to do, but simply whether he foretold that there would be a solar eclipse in that year, as stated by Herodotus. Now as to this there is quite a remarkable unanimity in the testimony of the ancients, and the evidence is of the strongest kind, ascending to Herodotus, and, according to the account of Diogenes Laërtius, even to Xenophanes, who was an Ionian, and not much later than Thales. Further, we know that in the 8th century B.C., there were observatories in most of the large cities in the valley of the Euphrates, and that professional astronomers regularly took observations of the heavens, copies of which were sent to the king of Assyria; and from a cuneiform inscription found in the palace of Sennacherib at Nineveh, the text of which is given by George Smith,[5] we learn that at that time the epochs of eclipses of both sun and moon were predicted as possible—probably by means of the cycle of 223 lunations or Chaldaean Saros—and that observations were made accordingly.

The wonderful fame of Thales amongst the ancients must have been in great part due to this achievement, which seems, moreover, to have been one of the chief causes that excited amongst the Hellenes the love of science which ever afterwards characterized them. Thales seems not to have left any writings behind him, though as to this there appears to be some doubt (see Diog. Laër. i. 23). Many anecdotes, amusing rather than instructive, are related of him, which have been handed down by Diogenes Laërtius and other writers. From some of them it would appear that he was engaged in trade, which is indeed expressly stated by Plutarch (*Solon*, c. 2). It is probable that in the pursuit of commerce he was led to visit Egypt. Of the fact that Thales visited Egypt, and there became acquainted with geometry, there is abundant evidence. Hieronymus of Rhodes (ap. Diog. Laër. i. 27) says, "he never had any teacher except during the time when he went to Egypt and associated with the priests."[6]

But the characteristic feature of the work of Thales was that to the knowledge thus acquired he added the capital creation of the geometry of lines, which was essentially abstract in its character. The only geometry known to the Egyptian priests was that of surfaces, together with a sketch of that of solids, a geometry consisting of some simple quadratures and elementary cubatures, which they had obtained empirically. Thales, on the other hand, introduced *abstract* geometry, the object of which is to establish precise relations between the different parts of a figure, so that some of them could be found by means of others in a manner strictly rigorous. This was a phenomenon quite new in the world, and due, in fact, to the abstract spirit of the Greeks.

The following discoveries in geometry are attributed to Thales:—(1) the circle is bisected by its diameter (Procl. *op. cit.* p. 157); (2) the angles at the base of an isosceles triangle are equal (*Id.* p. 250); (3) when two straight lines cut each other the vertically opposite angles are equal (*Id.* p. 299); (4) the angle in a semicircle is a right angle;[7] (5) the theorem Euclid i. 26 is referred to Thales by Eudemus (Procl. *op. cit.* p. 352). Two applications of geometry to the solution of practical problems are also attributed to him:—(1) the determination of the distance of a ship at sea, for which he made use of the last theorem; (2) the determination of the height of a pyramid by means of the length of its shadow: according to Hieronymus of Rhodes (Diog. Laër. i. 27) and Pliny (*N. H.* xxxvi. 12), the shadow was measured at the hour of the day when a man's shadow is the same length as himself. Plutarch, however, states the method in a form requiring the knowledge of Euclid vi. 4, but without the restriction as to the hour of the day (*Sept. Sap. Conviv.* 2). Further, we learn from Diogenes Laërtius (i. 25) that he perfected the things relating to the scalene triangle and the theory of lines. Proclus, too, in his summary of the history of geometry before Euclid, which he probably derived from Eudemus of Rhodes, says that Thales, having visited Egypt, first brought the knowledge of geometry into Greece,

[1] Bretschneider (*Die Geom. vor Euklides*, p. 40), without stating his authority, gives "between 585 and 583 B.C." as the date of the archonship of Damasius. In this he is followed by some other recent writers, who infer thence that the name "wise" was conferred on Thales on account of the success of his prediction. The date 586 B.C., given above, which is taken from Clinton, is adopted by Zeller.

[6] Cf. Pamphila and the spurious letter from Thales to Pherecydes, ap. Diog. Laër.; Proclus, *In primum Euclidis Elementorum Librum Commentarii*, ed. Friedlein, p. 65; Pliny, *H. N.* xxxvi. 12; Iamblichus, *In Vit. Pythag.* 12; Plutarch, *Sept. Sap. Conviv.* 2, *De Iside*, 10, and *Plac.* i. 3, 1.

[7] This is unquestionably the meaning of the statement of Pamphila (temp. Nero), ap. Diog. Laër. i. 24, that he was the first person to describe a right-angled triangle in a circle.

that he discovered many things himself, and communicated the beginnings of many to his successors, some of which he attempted in a more abstract manner (καθολικώτερον) and some in a more intuitional or sensible manner (αἰσθητικώτερον) (*op. cit.* p. 65).

From these indications it is no doubt difficult to determine what Thales brought from Egypt and what was due to his own invention. This difficulty has, however, been lessened since the translation and publication of the papyrus Rhind by Eisenlohr;[1] and it is now generally admitted that, in the distinction made in the last passage quoted above from Proclus, reference is made to the two forms of his work—αἰσθητικώτερον pointing to what he derived from Egypt or arrived at in an Egyptian manner, while καθολικώτερον indicates the discoveries which he made in accordance with the Greek spirit. To the former belong the theorems (1), (2), and (3), and to the latter especially the theorem (4), and also, probably, his solution of the two practical problems. We infer, then, [1] that Thales must have known the theorem that the sum of the three angles of a triangle are equal to two right angles. This inference is made from (4) taken along with (2). No doubt we are informed by Proclus, on the authority of Eudemus, that the theorem Euclid i. 32 was first proved in a general way by the Pythagoreans; but, on the other hand, we learn from Geminus that the ancient geometers observed the equality to two right angles in each kind of triangle—in the equilateral first, then in the isosceles, and lastly in the scalene (Apoll. *Conica*, ed. Halleius, p. 9), and it is plain that the geometers older than the Pythagoreans can be no other than Thales and his school. The theorem, then, seems to have been arrived at by induction, and may have been suggested by the contemplation of floors or walls covered with tiles of the form of equilateral triangles, or squares, or hexagons. [2] We see also in the theorem (4) the first trace of the important conception of geometrical loci, which we, therefore, attribute to Thales. It is worth noticing that it was in this manner that this remarkable property of the circle, with which, in fact, abstract geometry was inaugurated, presented itself to the imagination of Dante:—

> "O se del mezzo cerchio far si puote
> Triangol sì, ch'un retto non avesse."—*Par.* c. xiii. 101.

[3] Thales discovered the theorem that the sides of equiangular triangles are proportional. The knowledge of this theorem is distinctly attributed to Thales by Plutarch, and it was probably made use of also in his determination of the distance of a ship at sea.

Let us now consider the importance of the work of Thales. I. In a scientific point of view: (*a*) we see, in the first place, that by his two theorems he founded the geometry of lines, which has ever since remained the principal part of geometry; (*b*) he may, in the second place, be fairly considered to have laid the foundation of algebra, for his first theorem establishes an equation in the true sense of the word, while the second institutes a proportion.[2] II. In a philosophic point of view: we see that in these two theorems of Thales the first type of a natural law, *i.e.* the expression of a fixed dependence between different quantities, or, in another form, the disentanglement of constancy in the midst of variety—has decisively arisen.[3] III. Lastly, in a practical point of view: Thales furnished the first example of an application of theoretical geometry to practice,[4] and laid the foundation of an important branch of the same—the measurement of heights and distances. For the further progress of geometry see PYTHAGORAS.

As to the astronomical knowledge of Thales we have the following notices:—(1) besides the prediction of the solar eclipse, Eudemus attributes to him the discovery that the circuit of the sun between the solstices is not always uniform;[5] (2) he called the last day of the month the thirtieth (Diog. Laër. i. 24); (3) he divided the year into 365 days (*Id.* i. 27); (4) he determined the diameter of the sun to be the 720th part of the zodiac;[6] (5) he appears to have pointed out the constellation of the Lesser Bear to his countrymen, and instructed them to steer by it [as nearer the pole] instead of the Great Bear (Callimachus ap. Diog. Laër. i 23; cf. Aratus, *Phaenomena*, v. 36 seq.). Other discoveries in astronomy are attributed to Thales, but on authorities which are not trustworthy. He did not know, for example, that "the earth is spherical," as is erroneously stated by Plutarch (*Placita*, iii. 10); on the contrary, he conceived it to be a flat disk, and in this supposition he was followed by most of his successors in the Ionian schools, including Anaxagoras. The doctrine of the sphericity of the earth, for which the researches of Anaximander had prepared the way,[7] was in fact one of the great discoveries of Pythagoras, was taught by Parmenides, who was connected with the Pythagoreans, and remained for a long time the exclusive property of the Italian schools.[8] (G. J. A.)

Philosophy.—Whilst in virtue of his political sagacity and intellectual eminence Thales held a place in the traditional list of the wise men, on the strength of the disinterested love of knowledge which appeared in his physical speculations he was accounted a "philosopher" (φιλόσοφος). His "philosophy" is usually summed up in the dogma "water is the principle, or the element, of things"; but, as the technical terms "principle" (ἀρχή) and "element" (στοιχεῖον) had not yet come into use, it may be conjectured that the phrase "all things are water" (πάντα ὕδωρ ἐστί) more exactly represents his teaching. Writings which bore his name were extant in antiquity; but as Aristotle, when he speaks of Thales's doctrine, always depends upon tradition, there can be little doubt that they were forgeries.

From Aristotle we learn (1) that Thales found in water the origin of things; (2) that he conceived the earth to float upon a sea of the elemental fluid; (3) that he supposed all things to be full of gods; (4) that in virtue of the attraction exercised by the magnet he attributed to it a soul. Here our information ends. Aristotle's suggestion that Thales was led to his fundamental dogma by observation of the part which moisture plays in the production and the maintenance of life, and Simplicius's, that the impressibility and the binding power of water were perhaps also in his thoughts, are by admission purely conjectural. Simplicius's further suggestion that Thales conceived the element to be modified by thinning and thickening is plainly inconsistent with the statement of Theophrastus that the hypothesis in question was peculiar to Anaximenes. The assertion preserved by Stobaeus that Thales recognized, together with the material element "water," "mind," which penetrates it and sets it in motion, is refuted by the precise testimony of Aristotle, who declares that the early physicists did not distinguish the moving cause from the material cause, and that before Hermotimus and Anaxagoras no one postulated a creative intelligence.

It would seem, then, that Thales sought amid the variety of things a single material cause; that he found such a cause in one of the forms of matter most familiar to him, namely, water, and accordingly regarded the world and all that it contains as water variously metamorphosed; and that he asked himself no questions about the manner of its transformation.

The doctrine of Thales was interpreted and developed in the course of three succeeding generations. First, Anaximander chose for what he called his "principle" (ἀρχή), not water, but a corporeal element intermediate between fire and air on the one hand and water and earth on the other. Next, Anaximenes, preferring air, resolved its transformations into processes of thinning and thickening. Lastly, Heraclitus asserted the claims of fire, which he conceived to modify itself, not occasionally, but perpetually. Thus Thales recognized change, but was not careful to explain it; Anaximander attributed to change two directions; Anaximenes conceived the two sorts of change as rarefaction and condensation; Heraclitus, perceiving that, if, as his predecessors had tacitly assumed, change was occasional, the interference of a moving cause was necessary, made change perpetual. But all four agreed in tracing the variety of things to a single material cause, corporeal, endowed with qualities, and capable of self-transformation. A new departure was taken by the Eleatic Parmenides (*q.v.*), who, expressly noting that, when Thales and his successors attributed to the supposed element changing qualities, they became pluralists, required that the superficial variety of nature should be strictly distinguished from its fundamental unity. Hence, whereas Thales and his successors had confounded the One, the element, and the Many, its modifications, the One and the Not-One or Many became with Parmenides matters for separate investigation. In this way two lines of inquiry originated. On the one hand Empedocles and Anaxagoras, abandoning the pursuit of the One, gave themselves to the scientific study of the Many; on the other Zeno, abandoning the pursuit of the Many, gave himself to the dialectical study of the One. Both successions were doomed to failure; and the result

[6] This is the received interpretation of the passage in Diogenes Laërtius, i. 24 (see Wolf, *Gesch. der Astron.*, p. 169), where σεληναίου is probably a scribe's error for ζῳδιακοῦ. Cf. Apuleius, *Florida*, iv. 18, who attributes to Thales, then old, the discovery: "quotiens sol magnitudine sua circulum quem permeat metiatur."
[7] In likening the earth to a cylinder Anaximander recognized its circular figure in one direction.
[8] See G. V. Schiaparelli, *I Precursori di Copernico nell' Antichità*, p. 2 (Milan, 1873).

was a scepticism from which the thought of Greece did not emerge until Plato, returning to Parmenides, declared the study of the One and the Many, jointly regarded, to be the true office of philosophy. Thus, meagre and futile as the doctrine of Thales was, all the Greek schools, with the solitary exception of that of Pythagoras, took their origin from it. Not in name only, but also in fact, Thales, the first of the Ionian physicists, was the founder of the philosophy of Greece.

THALLIUM [symbol Tl, atomic weight 204·0 (O=16)], a metallic chemical element. It was discovered in 1861 by Sir William Crookes, who, during a spectroscopic examination of the flue-dust produced in the roasting of seleniferous pyrites occurring at Tilkerode in the Harz, observed a green line foreign to all then known spectra. He concluded that the mineral contained a new element, to which he gave the name of thallium, from θαλλός, a green twig. Crookes presumed that his thallium was something of the order of sulphur, selenium or tellurium; but Lamy, who anticipated him in isolating the new element, found it to be a metal. Our knowledge of the chemistry of thallium is based chiefly upon the labours of Crookes.

The chemical character of thallium presents striking peculiarities. Dumas once called it the "*ornithorhynchus paradoxus* of metals." As an elementary substance, it is very similar in its physical properties to lead; it resembles lead chemically inasmuch as it forms an almost insoluble chloride and an insoluble iodide. But the hydroxide of thallium, in most of its properties, comes very close to the alkali metals; it is strongly basic, forms an insoluble chloroplatinate, and an alum strikingly similar to the corresponding potassium compounds. Yet, unlike potassium or lead, it forms a feebly basic sesquioxide similar to manganic oxide, Mn_2O_3.

Traces of thallium exist in many kinds of pyrites, as used for vitriol-making. The only known mineral of which it forms an essential component is the rare mineral crookesite of Skrikerum, Småland, Sweden, which, according to Nordenskiöld, contains 33·3 per cent. of selenium, 45·8 per cent. of copper, 3·7 per cent. of silver, and 17·2 per cent. of thallium. The best raw materials for the preparation of thallium are the flue-dusts produced industrially in the roasting of thalliferous pyrites and the "chamber muds" accumulating in vitriol-chambers wrought with such pyrites; in both it is frequently associated with selenium. The flue-dust from the pyrites of Theux, near Spa (Belgium), according to Böttcher, contains 0·5 to 0·75 per cent. of thallium; that of the pyrites of Meggen, according to Carstanjen, as much as 3·5 per cent.; while that of the pyrites of Ruhrort yielded 1 per cent. of the pure chloride to Gunning.

For the extraction of the metal from chamber mud, the latter is boiled with water, which extracts the thallium as the sulphate. From the filtered solution the thallium is precipitated as the chloride by addition of hydrochloric acid, along, in general, with more or less of lead chloride. The mixed chlorides are boiled down to dryness with sulphuric acid to convert them into sulphates, which are then separated by boiling water, which dissolves only the thallium salt. From the filtered solution the thallium is recovered, as such, by means of pure metallic zinc, or by electrolysis. The (approximately pure) metallic sponge obtained is washed, made compact by compression, fused in a porcelain crucible in an atmosphere of hydrogen, and cast into sticks.

Metallic thallium is bluish white; it is extremely soft and almost devoid of tenacity and elasticity. Its specific gravity is 11·86. It fuses at 290° C.; at a white heat it boils and can be distilled in hydrogen gas. Its vapour density at 1728° corresponds to the molecule Tl_2. Its salts colour the Bunsen flame a bright green. When heated in air it is readily oxidized, with the formation of a reddish or violet vapour. When exposed to the air it becomes quickly covered with a film of oxide; the tarnished metal when plunged into water reassumes its metallic lustre, the oxide film being quickly dissolved. When kept in contact with water and air it is gradually converted into hydroxide, TlOH. It decomposes water at a red heat, liberating hydrogen and being itself converted into the hydrate. It is readily soluble in nitric and sulphuric acids, but less so in hydrochloric.

Thallium forms two series of salts: thallous, in which the metal is monovalent; and thallic, in which it is trivalent. In the thallous series many analogies with lead compounds are observed; in the thallic some resemblance to aluminium and gold.

Thallous hydroxide, TlOH, is most conveniently prepared by decomposing the solution of the sulphate with baryta water. It crystallizes from its solution in long yellow needles, TlOH or $TlOH+H_2O$, which dissolve readily in water, forming an intensely alkaline solution, which acts as a caustic, and like it greedily absorbs carbonic acid from the atmosphere. Unlike the alkalis, it readily loses its water at 100° C. and even at the ordinary temperature, to form the oxide Tl_2O, which is black or black-violet. *Thallic oxide*, TlO or Tl_2O_2, was obtained by O. Rabe (*Abst. J.C.S.*, 1907, ii. 769) by acting with hydrogen peroxide on an alkaline solution of thallous sulphate at low temperatures, an initial red precipitate rapidly changing into a bluish-black compound. It melts at 720° and decomposes rapidly above 800°, giving oxygen and thallous oxide. *Thallous chloride*, TlCl, is readily obtained from the solution of any thallous salt, by the addition of hydrochloric acid, as a white precipitate similar in appearance to silver chloride, like which it turns violet in the light and fuses below redness into a (yellow) liquid which freezes into a horn-like flexible mass. It is also formed when the metal is burnt in chlorine. The specific gravity of this "horn" thallium is 7·02. One part of the precipitated chloride dissolves at 0° C. in 500 parts of water, and in 70 parts at 100° C. It is less soluble in dilute hydrochloric acid. Carbonate of soda solution dissolves it pretty freely. *Thallous iodide*, TlI, is obtained as a yellow precipitate, which requires 16,000 parts of cold water for its solution, by the addition of potassium iodide to a solution of a thallous salt, or by the direct union of its components. The yellow crystals melt at 190°, and when cooled down assume a red colour, which changes to the original yellow on standing. *Thallous bromide*, TlBr, is a light yellow crystalline powder; it is formed analogously to the chloride. *Thallous fluoride*, TlF, forms white glistening octahedra; it is obtained by crystallizing a solution of the carbonate in hydrofluoric acid. It resembles potassium fluoride in forming an acid salt, $TlHF_2$. *Thallous chloroplatinate*, Tl_2PtCl_6, readily obtainable from thallous salt solutions by addition of platinum chloride, is a yellow precipitate soluble in no less than 15,600 parts of cold water. *Thallous perchlorate*, $TlClO_4$, and *periodate*, $TlIO_4$, are interesting inasmuch as they are isomorphous with the corresponding potassium salts. Other instances of the isomorphism of thallous with potassium salts are the nitrates, phosphates, hydrazoates, sulphates, chromates, selenates, and the analogously constituted double salts, and also the oxalates, racemates and picrates. *Thallous carbonate*, Tl_2CO_3, more nearly resembles the lithium compound than any other ordinary carbonate. It is produced by the exposure of thallous hydrate to carbon dioxide, and therefore is obtained when the moist metal is exposed to the air. It forms resplendent monoclinic prisms, soluble in water. *Thallous sulphate*, Tl_2SO_4, forms rhombic prisms, soluble in water, which melt at a red heat with decomposition, sulphur dioxide being evolved. It unites with sulphuric acid giving an acid salt, $TlHSO_4 \cdot 3H_2O$, and with aluminium, chromium and iron sulphates to form an "alum." It also forms double salts of the type $Tl_2SO_4(Mg,Fe,ZnSO_4) \cdot 6H_2O$. *Thallous sulphide*, Tl_2S, is obtained as a black precipitate by passing sulphuretted hydrogen into a thallous solution. It is insoluble in water and in the alkalis, but readily dissolves in the mineral acids. On thallium sulphides see H. Pélabon, *Abst. J.C.S.*, 1907, ii. 770. *Thallous nitrate*, $TlNO_3$, is obtained as white, rhombic prisms by crystallizing a solution of the metal, oxide, carbonate, &c., in nitric acid. Various thallous phosphates are known. The normal salt, Tl_3PO_4, is soluble in 200 parts of water, and may be obtained by precipitation. On thallous salts see W. Stortenbeker, *Abst. J.C.S.*, 1907, ii. 770. *Thallic oxide*, Tl_2O_3, is obtained as a dark reddish powder, insoluble in water and alkalis, by plunging molten thallium into oxygen, or by electrolysing water, using a thallium anode. *Thallic hydroxide*, $Tl(OH)_3$, is obtained as a brown precipitate by adding a hot solution of thallous chloride in sodium carbonate to a solution of sodium hypochlorite. On drying it has the composition TlO(OH). Hydrochloric acid gives thallous chloride and chlorine; sulphuric acid gives off oxygen; and on heating it first gives the trioxide and afterwards the monoxide. The hydroxide is obtained as brown hexagonal plates by fusing thallic oxide with potash to which a little water has been added. *Thallic chloride*, $TlCl_3$, is obtained by treating the monochloride with chlorine under water; evaporation in a vacuum gives colourless deliquescent crystals of $TlCl_3 \cdot H_2O$. By heating the metal or thallous chloride in chlorine, $TlCl \cdot TlCl_2$ is obtained, which on further heating gives $3TlCl \cdot TlCl_3$ as a yellowish brown mass. The chloride when anhydrous is a crystalline mass which melts at 24°. It forms several double salts, *e.g.* with hydrochloric acid and the alkaline chlorides, and also with nitrosyl chloride. The chlorine is not completely precipitated by silver nitrate in nitric acid solution, the ionization apparently not proceeding to all the chlorine atoms. *Thallic iodide*, TlI_3, is interesting on account of its isomorphism with rubidium and caesium tri-iodides, a resemblance which suggests the formula $TlI(I_2)$ for the salt, in which the metal is obviously monovalent. On the halogen compounds see V. Thomas, *Abst. J.C.S.* (1907), ii. 547. *Thallic sulphate*, $Tl_2(SO_4)_3 \cdot 7H_2O$, and *thallic nitrate*, $Tl(NO_3)_3 \cdot 8H_2O$, are obtained as colourless crystals on the evaporation of a solution of the oxide in the corresponding acid. The sulphate decomposes into sulphuric acid and the trioxide on warming with water, and differs from aluminium sulphate in not forming alums.

Analysis.—All thallium compounds volatile or liable to dissociation at the temperature of the flame of a Bunsen lamp impart to such flame an intense green colour. The spectrum contains a bright green of wave-length 5351. From solutions containing it as thallous salt the metal is easily precipitated as chloride, iodide, or chloroplatinate by the corresponding reagents. Sulphuretted hydrogen, in the presence of free mineral acid, gives no precipitate; sulphide of ammonium, from neutral solutions, precipitates Tl_2S as a dark brown or black precipitate, insoluble in excess of reagent. Thallic salts are easily reduced to thallous by means of solution of sulphurous acid, and thus rendered amenable to the above reactions. The chloroplatinate serves for the quantitative estimation. L. F. Hawley employs sodium thiostannate which precipitates thallium as Tl_2SnS_4, insoluble in water, and which may be dried on a Gooch filter at 105°. It may be noted that all thallium compounds are poisonous.

The atomic weight of thallium was determined very carefully by Crookes, who found $Tl = 204 \cdot 2$ $(O = 16)$; this figure was confirmed by Lepierre in 1893.

THALWEG (a German word compounded from *Thal*, valley, and *Weg*, way) in physical geography, a term adopted into English usage signifying the line of greatest slope along the bottom of a valley, *i.e.* a line drawn through the lowest points of a valley in its downward slope. It thus marks the natural direction of a watercourse.

THAMES, the chief river of England, rising in several small streams among the Cotteswold Hills in Gloucestershire. Its source is generally held to be at a place known as Thames Head, in the parish of Coates, 3 m. W. by S. of Cirencester; but claims have also been advanced on behalf of the Seven Springs, the head waters of the river Churn, 5 m. S. of Cheltenham. The length of the river from Thames Head Bridge to London Bridge is 161¼ m. and from London Bridge to the Nore, 47¾ m., a total of 209 m. The width at Oxford is about 150 ft., at Teddington 250 ft., at London Bridge 750 ft., at Gravesend 2100 ft., and between Sheerness and Shoeburyness, immediately above the Nore, 5½ m. The height of Thames Head above sea-level is 356 ft., but that of Seven Springs, the adoption of which as the source would extend the length of the river by several miles, is 700 ft. The height of the river at Lechlade is 237 ft., the average fall between Lechlade and London, 143¼ m., being rather less than 20 in. per mile. The drainage area of the Thames is 5924 sq. m., including that of the Medway, which, as it joins the estuary immediately above Sheerness, may be considered a tributary of the Thames. The Thames forms part of the Gloucestershire-Wiltshire boundary to a point below Lechlade; thence for a short distance it separates Gloucestershire from Berkshire; after which it separates successively Oxfordshire and Berkshire, Buckinghamshire and Berkshire, Middlesex and Surrey, and finally, at its estuary, Essex and Kent. In the succeeding paragraph the bracketed figures indicate the distance in miles above London Bridge.

The upper course lies through a broad valley, between the foot-hills of the Cotteswolds on the north, and the slight elevations dividing it from the Vale of White Horse on the south. The scenery is rural and pleasant; the course of the river winding. Before reaching Oxford the stream swings north, east and south to encircle the wooded hills of Wytham and Cumnor, which overlook the city from the west. The Windrush joins from the north (left) at New Bridge (126¾), the Evenlode near Eynsham (119), and the Cherwell at Oxford (112). Between Lechlade and Oxford the main channel sends off many narrow branches; the waters of the Windrush are similarly distributed, and the branches in the neighbourhood of Oxford form the picturesque "backwaters" which only light pleasure boats can penetrate. The river then follows a valley confined between the hills on either side of Oxford, passes the pleasant woods of Nuneham, and at Abingdon (103½) receives the Ock from the Vale of White Horse. At Dorchester (95¼) the Thame enters on the left, and the river then passes Wallingford (90¾) and Goring (85). Hitherto from Oxford its course, though greatly winding, has lain generally in a southerly direction, but it now bends eastward, and breaches the chalk hills in a narrow gap, dividing the Chilterns from the downs of Berkshire or White Horse Hills. From this point as far as Taplow the southern slopes of the Chilterns descend more or less closely upon the river; they are finely wooded, and the scenery is peculiarly beautiful, especially in early summer. The charm of the Thames is indeed maintained throughout its course; the view of the rich valley from Richmond Hill, of the outskirts of London, is celebrated; the river is practically the only physical attribute to the beauty of the metropolis itself, and the estuary, with its burden of shipping and its industrial activity, is no less admirable. At Pangbourne (80¾) the Thames receives the Pang on the right, and at Reading (74½) the Kennet on the same side. After passing Reading it bends northward to Henley (65), eastward past Great Marlow (57) to Bourne End (54), and southward to Taplow and Maidenhead (49¾), receiving the Loddon on the right near Shiplake above Henley. Winding in a south-easterly direction, it passes Eton and Windsor (43¼), Datchet (41½), Staines (36), Chertsey (32), Shepperton (30) and Sunbury (26½), receiving the Coln from the left at Staines, and the Wey from the right near Shepperton. Flowing past Hampton Court, opposite to which it receives the Mole on the right, and past Kingston (20½), it reaches Teddington (18¾). Passing Richmond (16) and Kew the river flows through London and its suburbs for a distance of about 25 m., till it has passed Woolwich. Gravesend, the principal town below Woolwich, is 26½ m. from London Bridge. The estuary may be taken to extend to the North Foreland of Kent. In the tideway the principal affluents of the Thames are the Brent at Brentford, the Wandle at Wandsworth, the Ravensbourne at Deptford, the Lea at Blackwall, the Darent just below Erith, and the Ingrebourne at Rainham, besides the Medway.

The basin of the Thames is of curiously composite character. Thus, the upper portion of the system, above the gap at Goring, is a basin in itself, defined on the west and south by the Cotteswold and White Horse Hills and on the east and north by the Chilterns and the uplands of Northamptonshire. But there are several points at which its division from other river basins is only marked by a very low parting. Thus a well-marked depression in the Cotteswolds brings the head of the (Gloucestershire) Coln, one of the head-streams of the Thames, very close to that of the Isborne, a tributary of the upper Avon; the parting between the head-streams of the Thames and the Bristol Avon sinks at one point, near Malmesbury, below 300 ft.; and head-streams of the Great Ouse rise little more than two miles from, and only some 300 ft. above, the middle valley of the Cherwell. The White Horse Hills and the Chilterns strike right across the Thames basin, but almost their entire drainage from either flank lies within it, and similarly a great part of the low-lying Weald, though marked off from the rest of the basin by the North Downs, drains into it through these hills. It may be noted further that the Kennet continues upward the line of the main valley below the Goring gap, and the Cherwell that of the main valley above it. The basin thus presents interesting problems. The existence of wide valleys where the small upper waters of the Cherwell, Evenlode and Coln now flow, the occurrence of waterborne deposits in their beds from the north-west of England and from Wales, and the fact that the Thames, like its lower southern tributaries which pierce the North Downs, has been able to maintain a deep valley through the chalk elevation at Goring, are considered to point to the former existence of a much larger river, in the system of which were included the upper waters of the present Severn, Dee and other rivers of the west. The question, in fact, involves that of the development of a large part of the hydrography of England.

The Thames about Oxford is often called the Isis. Camden gave currency to the derivation of the word from the combination of the names Thame and Isis. But it can be shown conclusively that the river has borne its present designation from the earliest times. Caesar (*De Bell. Gall.* v. 11) says that at the time of his invasion of Britain it was called Tamesis. Dion Cassius (xl. 3) and Tacitus (*Ann.* xiv. 32) both call it Tamesa, and in no early authority is the name Isis used. In early Saxon times the river was called Thamis, as may be seen in a grant before A.D. 675 to Chertsey Abbey by the sub-king Frithwald. In the first statute passed for improving the navigation of the river near Oxford (21 Jac. I.) it is called the river of Thames, and it was only in a statute of George II. (1751) that the word Isis appears. The name Isis has indeed the authority of Spenser as applied to the Thames in its course above Dorchester (*Faerie Queen*, Bk. iv. canto xi. stanza 24), but there is ample evidence to show that long before his time the name of the river throughout its course was not Isis but Thames. The word Isis is probably an academic rendering of Ouse or Isca, a common British river name, but there is no reason to suppose that it ever had much vogue except in poetry or in the immediate neighbourhood of Oxford.

The flow of the Thames varies greatly, according to the season of the year. The average gaugings at Teddington for the summer months of the years 1883 to 1900 were in July 413,000,000 gallons a day, in August 395,000,000 gallons, and in September 375,000,000 gallons. The normal natural flow in ordinary summer weather is about 350,000,000 gallons a day, and of this, after the companies have taken 130,000,000, only 220,000,000 gallons are left to pass over Teddington Weir. After a long period of dry weather the natural flow has been known to fall considerably below 200,000,000 gallons, whilst, on the other hand, in the rainy winter season, the flow in 1894 rose for a short time to as high a figure as 20,000,000,000 gallons, and the ordinary flow in winter months may be put down as 3,000,000,000 gallons. The importance of storage reservoirs is manifest under such conditions of flow, especially bearing in mind the growth of population in the London district and of its increasing needs. The water-supply of London is considered under that heading; it may be noted here that the Thames forms the chief source of supply for the metropolis, but apart from this the corporation of Oxford and two companies in the Staines district have powers to draw water from the river, though not in any large quantities.

Throughout the whole of the Thames watershed, and especially in the 3800 sq. m. above the intakes of the water companies (at Hampton or in the vicinity), the Thames Conservancy has enforced the requirements of parliament that no sewage or other pollution shall be allowed to pass into the Thames, into its tributary streams, or even into any water communicating with them. There is a large staff of inspectors constantly visiting the various parts of the watershed, and in spite of many difficulties arising from vested interests, the work of purification is attaining completion, with a correspondingly great improvement in the quality of the river water. So recently as 1890 the state of the river below London was such as to be dangerous to the public health. The metropolitan sewage was discharged untreated into the river, and the heavier solids deposited over the river-bed, while the lighter parts flowed backwards and forwards on the tide. The London County Council, directly after its establishment, took means to remedy this evil (see LONDON).

The Thames is navigable for rowing-boats as far upwards as Cricklade, except in dry seasons, and for barges at all times as far as Lechlade, 18 m. below Thames Head. At Inglesham, three-quarters of a mile above Lechlade, the Thames and Severn canal has its junction with the Thames. This canal is the link between the two great rivers from which it takes its name, or, in other words, between the east and west of England. It surmounts the watershed by means of Sapperton tunnel, 2 m. long, opened in 1789, and joins the Stroudwater canal, which completes the connexion, at Wallbridge near Stroud. It was long abandoned, but owing to the exertions of a joint committee of the counties and other interests concerned in 1895, powers were obtained from parliament for its restoration, and the works needful for its re-opening were carried out. Concurrently with the repair of the canal, the navigation works on the Thames were remodelled at a large cost, and barges drawing 3 ft. 6 in. can now, even in the summer season, navigate from London to Inglesham. Although the Thames, as one of the "great rivers of England," was always a navigable river, that is to say, one over which the public had the right of navigation, it was not until the last quarter of the 18th century that any systematic regulation of its flow in the upper reaches was attempted. Complaints of the obstructions in it are not uncommon, and John Taylor, the Water Poet (1580–1653), in a poem commemorating a voyage from Oxford to London, bewails the difficulties he found on the passage. No substantial measures to remedy this state of things were adopted till 1771, when an act of parliament was passed authorizing the construction of pound locks on the Thames above Maindenhead Bridge. In pursuance of the powers thus granted, the Thames Commissioners of that day caused locks to be built at various points above Maidenhead, and between 1810 and 1815 the Corporation of London carried out river works on the same lines as far down the river as Teddington. The works as subsequently maintained by the Thames Conservancy ensure an efficient head of water during the drier seasons of the year, and facilitate the escape of winter floods. The number of locks is 47, including four navigation weirs above Oxford. The uppermost lock is St John's, below Lechlade; the lowest is Richmond, but this is a half-tide lock, keeping the water above at a level corresponding to half that of flood tide. Under ordinary conditions the sluices are raised to admit boats to pass from the half flood to half ebb, so that the river remains tidal up to Teddington, the next lock.

The canals in use communicating with the Thames, in addition to the Thames and Severn canal, are the Oxford canal, giving communication from that city with the north, the Kennet and Avon canal from Reading to the Bristol Avon, the Grand Junction at Brentford, the Regent's canal at Limehouse, and the Grand Surrey canal at Rotherhithe. A short canal connects Gravesend with Higham. Navigation is also carried on by the Medway to Tonbridge, on the lower parts of the Darent and Cray, from Dartford and Crayford, and on the Wey up to Guildford and Godalming. The Woking, Aldershot and Basingstoke canal joins the Wey, but is little used. The Wilts and Berks canal, joining the Thames at Abingdon, is disused. By means of the Grand Junction and Oxford canals especially, constant communication is maintained between the Thames and the great industrial centres of England. The trade on the upper Thames is steady, though not extensive. The vast trade on the estuary, which lies within the bounds of the port of London, is considered under LONDON.

The utility of the river is great in the opportunities for exercise and recreation which it affords to the public, especially to Londoners. The scene on any part of the river from Oxford down on public holidays, and on Saturdays and Sundays during the summer, would be sufficient to show how it contributes to the public enjoyment. It is only since about 1870 that this popularity has grown up. Ten years earlier even rowing-boats were few excepting at Oxford, at Henley in regatta time, and at Putney on the tideway. Steam launches did not exist on the river before 1866 or 1867, and house-boats only in the form of college barges at Oxford. But by 1900 there were 541 launches, 162 house-boats, and 11,284 rowing-boats. Each boat is registered, a small tax being charged; while there are fixed prices for the passage of locks. During the season regattas take place at many of the towns and larger villages. Of these Henley Royal Regatta is pre-eminent by the number and importance of the entries, and by its comparative antiquity. The regattas at Molesey, Kingston, Reading, Marlow and Oxford, as well as many others, attract numerous competitors and spectators. The Oxford and Cambridge boat-race from Putney to Mortlake on the tideway, the summer eights and the "torpids" at Oxford University, and the school races at Eton and Radley should also be mentioned.

A statute of 1393 was granted to the citizens of London to remove weirs on the Thames, and empowered the Lord Mayor to enforce its provisions. For the next four centuries he acted through water-bailiffs, till in 1771 a committee of the Corporation of London took over the work. In 1857 the Thames Conservancy Board was established. Its powers were increased and its constitution varied in 1864, 1866 (till which year the jurisdiction of the river above Staines was under a large body of commissioners), and 1894, but the creation of the Port of London Authority (see LONDON) limited its jurisdiction.

Fish are abundant, especially coarse fish such as pike, perch, roach, dace and barbel. Of trout there are many fine specimens, especially at the weirs. Salmon are known to have existed at Maidenhead so recently as 1812, but they disappeared soon after that date. An association was formed under the presidency of Mr W. H. Grenfell, M.P., with the object of reintroducing this fish into the river, and in April 1901 and on subsequent occasions a number of young salmon were placed at Teddington by way of experiment. The right of the public to take fish has been frequently in dispute, but a committee of the House of Commons, which took much evidence on the question in the year 1884, came to the conclusion that "it is impossible to recognize anything like a general public right to take fish as now existing." They added "that the public at large have only to know that their rights are imaginary to induce them also to be content with the extant system under which permission is very freely granted by owners of fisheries to the public for angling on the more frequented parts of the Thames." These conclusions are interesting in face of the fact that the question has arisen from time to time since 1884.

The fisheries are under the regulation of by-laws made by the Thames Conservancy, which apply to the riparian owners as well as to the public generally. These by-laws are carried into effect by officers of the conservators, assisted by the river-keepers of the various fishing associations. The principal associations are those at Oxford, Reading, Henley, Maidenhead and Windsor, and the Thames Angling Preservation Society, whose district is from Staines to Brentford.

THAMES, a seaport and gold-mining centre in North Island, New Zealand, in the county and at the mouth of the river of its name, on the Firth of Thames, a deep inlet of the Hauraki Gulf of the east coast. Pop. (1906) 3750. It comprises under one municipality the settlement formerly called Grahamstown, with its suburbs Shortland and Tararu. It lies 42 m. S.E. of Auckland by the steamer-route, a pleasant journey among the islands of the Gulf. There is also railway communication with Auckland (but by a circuitous route of 120 m.), and with the neighbouring districts by branch lines. The harbour is good; the industries include foundries, shipbuilding yards and saw-mills. The sea fisheries are valuable, a large part of the yield being exported to Auckland. The inland district watered by the Thames river is auriferous; Waitekuri (40 m.) and Karangahake (28 m. S. of Thames) are centres of operations. The small town of Te Aroha (32 m. by rail), on the river, besides being the centre of mining and agricultural industries, is a favourite health resort on account of its hot medicinal springs. The river is navigable for steamers of light draught. The scenery along its course is pleasant, and at Ohinemuri (20 m. from Thames) it flows through a fine gorge.

THANA, or TANNA (=a fort, or police-station), a town and district of British India, in the Northern division of Bombay. The town is on the west of the Salsette creek or Thana river, just where the Great Indian Peninsula railway crosses to the mainland, 21 m. from Bombay city. Pop. (1901) 16,011.

The DISTRICT OF THANA has an area of 3573 sq. m. It extends along the coast for 105 m., with a breadth of 50 m., and is confined between the Western Ghats on the E. and the sea on the W., while on the N. it is bounded by the Portuguese territory of Damaun and by Surat district, and on the S. by Kolaba district. The district is well watered and wooded, and, except in the nort-east, is a low-lying rice tract broken by hills. Most of the hills were once fortified, but the forts built on them are now dilapidated and useless. Matheran (*q.v.*) is a favourite summer resort for the citizens of Bombay. The only rivers of any importance are the Vaitarna and the Ulhas, the former being navigable for a distance of about 20 m. from its mouth; the latter is also navigable in parts for small craft. There are no lakes; but the Vehar and the Tulsi, formed artificially, supply Bombay city with water. In 1901 the population was 811,433, showing a decrease of 1 per cent. in the decade. The staple crop is rice. Fishing supports many of the people, and the forests yield timber and other produce. Salt is largely manufactured by evaporation along the coast. At Kurla, in Salsette island, there are cotton mills and rice mills. The district is traversed throughout its length by the Bombay and Baroda railway, and also crossed by the two branches of the Great Indian Peninsula line.

The territory comprised in the district of Thana (apart from Salsette island, which was acquired in 1782) formed part of the dominions of the peshwa, and was annexed by the British in 1818 on the overthrow of Baji Rao. Since then the operations to put down the Koli robbers, which extended over several years, have been the only cause of serious trouble.

THANESAR (="place of the god"), an ancient town of British India, in Karnal district of the Punjab, on the river Saraswati, 100 m. by rail N. of Delhi: pop. (1901) 5066. As the centre of the tract called Kurukshetra in the Mahabharata, it has always been a holy place, and was in the seventh century the capital of King Harshavardhana, who ruled over all northern India. The bathing-fair held here on the occasion of a solar eclipse is said to be attended by half a million pilgrims.

THANET, ISLE OF, the extreme north-eastern corner of Kent, England, insulated by the two branches of the river Stour, and forming one of the eight parliamentary divisions of the county. Its name is said to be derived from Saxon *tene*, a beacon or fire (probably from the number of watch-fires existing on this easily ravaged coast), and numerous remains of Saxon occupation have been found, as at Osengal near Ramsgate. Thanet is roughly oblong in form, its extreme measurements being about 8 m. from E. to W., and 5 m. from N. to S. The branches of the Stour dividing near Sarre take the place of the former Wantsume, a sea-passage which had diminished in breadth to half a mile in the time of Augustine. The Wantsume was guarded by the Roman strongholds of *Regulbium* (Reculver) in the north and *Rutupiae* (Richborough) in the south, and was crossed by ferries at Sarre and Wade. With the drying up of this channel and the closing of Sandwich harbour in the 16th century, the present marshlands or level to the south and west of the isle were left. The sea-face of Thanet consists mainly of bold slopes or sheer cliffs, and the eastern extremity is the fine headland of the North Foreland. Containing the popular seaside resorts of Ramsgate, Broadstairs, Margate and Westgate, Thanet is served by the South-Eastern & Chatham railway, and Minster is a junction station of the lines to Ramsgate and Sandwich respectively.

THANKSGIVING DAY, in the United States, the fourth Thursday in November, annually set apart for thanksgiving by proclamation of the president and of the governors of the various states. The day is observed with religious services in the churches, and, especially in New England, as an occasion for family reunion. The Pilgrims set apart a day for thanksgiving at Plymouth immediately after their first harvest, in 1621; the Massachusetts Bay Colony for the first time in 1630, and frequently thereafter until about 1680, when it became an annual festival in that colony; and Connecticut as early as 1639 and annually after 1647, except in 1675. The Dutch in New Netherland appointed a day for giving thanks in 1644 and occasionally thereafter. During the War of Independence the Continental Congress appointed one or more thanksgiving days each year, except in 1777, each time recommending to the executives of the various states the observance of these days in their states. President Washington appointed a day of thanksgiving (Thursday, the 26th of November) in 1789, and appointed another in 1795. President Madison, in response to resolutions of Congress, set apart a day for thanksgiving at the close of the War of 1812. One was annually appointed by the governor of New York from 1817. In some of the Southern States there was opposition to the observance of such a day on the ground that it was a relic of Puritanic bigotry, but by 1858 proclamations appointing a day of thanksgiving were issued by the governors of twenty-five states and two Territories. President Lincoln appointed the fourth Thursday of November 1864, and since that time each president has annually followed his example.

See F. B. Hough, *Proclamations for Thanksgiving* (Albany, 1858); W. D. Love, *The Fast and Thanksgiving Days of New England* (Boston, 1895); May Lowe, "Thanksgiving Day" in *New England Magazine* (Nov. 1904); C. L. Norton, "Thanksgiving Day, Past and Present," in the *Magazine of American History* (Dec. 1885); R. M. Schauffler (ed.), *Thanksgiving* (New York, 1907).

THANN, a town of Germany, in Upper Alsace, 16 m. by rail N.W. of Mülhausen. Pop. (1905) 7901. It is the seat of cotton, calico, silk, machinery and other industries, and excellent wine is grown there. The (Roman Catholic) church of St Theobald (1351) is an elegant specimen of Gothic, and has a remarkably fine tower (1450–1516), 266 ft. high. Above the town are the ruins of the castle of Engelburg, destroyed by Turenne in 1675.

THAPSACUS, the "large and prosperous city" on the Arabian side of the Euphrates where Cyrus the Younger revealed to the Greeks the object of his expedition (Xen. *Anab.* i. 4, 11). No such place has yet been found mentioned in cuneiform texts. We may have a Semitic form of the name in the Hebrew Tiphsah; but it is impossible to determine whether the one phrase[1] "from Tiphsah to Gaza" (1 Kings v. 4—iv. 24 in the English version), where the name seems to occur, is as early

[1] 2 Kings xv. 16 cannot possibly refer to any place on the Euphrates.

as the Persian period: the Greek text is quite discrepant. Thapsacus was the crossing-place of Darius Codomannus, before and after his defeat (Arrian ii. 13), and of Alexander (iii. 7), and in Strabo's time it was the usual crossing-place (xvi. 1, 21); but Tiglath-pileser I. and Assur-nasir-pal crossed considerably farther north, and we have no reason to suppose that they were not simply following the practice of those early times; and we do not know when the custom of crossing at Thapsacus which the Hebrew text of the passage in 1 Kings may presuppose sprang up. Xenophon's army had to be content with fording the stream. Alexander, however, effected his crossing (Arrian, iii. 7) by two connected bridges (of boats?), and it was from this place that later he had the material for his fleet sent down (Arrian vii. 19; Strabo xvi. 741) to Babylonia. His successors must also have valued the place, for according to Pliny (v. 87) it bore later the name of Amphipolis, perhaps bestowed on it (Steph. Byz., Appian *Syr.* 57) by Seleucus I., although the name, like so many others, probably failed to win acceptance; and in the time of Eratosthenes the position of Thapsacus had become so central that he chose it as the point from which to make his measurements for all Asia (Strabo ii. 79, 80), and in the time of Strabo himself it was there that goods were embarked for transport down the Euphrates (Q. Curt. x. 1), and landed after having come by stream from lower districts (Strabo xvi. 1, 23). After Pliny the city is not again mentioned.[1]

After various attempts at identification (see Ritter, *Erdkunde*) it has apparently been correctly identified by J. P. Peters (*Nation*, May 23, 1889) and B. Moritz (*Sitz.-Ber. d. Berl. Akad.*, July 25, 1889). The name may survive in *Kal'at Dibse*, "a small ruin 8 m. below Meskene, and 6 m. below the ancient Barbalissus." See J. P. Peters, *Nippur*, 196 ff. (H. W. H.)

THAPSUS, a low peninsula, now known as Magnisi, joined by a narrow isthmus to the mainland of Sicily, about 7 m. N.N.W. of Syracuse. The founders of Megara Hyblaea settled here temporarily, according to Thucydides, in the winter of 729–728 B.C., but it seems to have remained almost if not entirely uninhabited until the Athenians used it as a naval station in their attack on Syracuse early in 414 B.C. A number of tombs were excavated in 1894, containing objects belonging to a transitional stage between the second and third Sicel period, attributable roughly to 1000–900 B.C., and with a certain proportion of Mycenean importations.

See Orsi in *Monumenti dei Lincei* (1897), vi. 89–150.

THAR AND PARKAR, or THUR AND PARKER, a district of British India in the Sind province of Bombay. Area, 13,941 sq. m. The district is divided into two portions. The western part, called the "Pat," is watered by the Eastern Nara and the Mithrau canals, which constitute the sole water-system of the district, and the presence of water has created a quantity of jungle and marsh; the other part, called the "Thar," is a desert tract of rolling sand-hills, running north-east and south-west, composed of a fine but slightly coherent sand. To the south-east of Thar is Parkar, where there are ranges of rocky hills, rising to 350 ft. above the surrounding level, and open plains of stiff clay. This portion contains the ruins of several old temples. The climate is subject to considerable extremes in temperature, being excessively hot in the summer and very cold in winter, the cold increasing as the sand-hills are approached. In 1901 the population was 389,714, showing an increase of 22 per cent. in the decade. The principal crops are millets, rice, wheat, oil-seeds and cotton. Cultivation largely depends upon the control of the water which comes down the canals and occasionally causes flood. Salt is found in two or three places. The western border of the district is entered by the narrow-gauge railway from Hyderabad to Shadipalli, connected with the North-Western main line by a bridge across the Indus at Kotri, and with the Rajputana system at Jodhpur. Umarkot, the administrative headquarters of the district, is on the edge of the desert. Pop. (1901) 4924. It is historically interesting as the birthplace of the emperor Akbar in 1542.

Very little is known of the early history of the district. The Soda Rajputs, said to be descendants of Parmar Soda, are supposed to have come into this part of Sind about 1226. when they quickly displaced the rulers of the country, though, according to other authorities, they did not conquer the country from the Sumras, the dominant race, before the beginning of the 16th century. The local dynasty of the Sodas succumbed to the Kalhoras about 1750, since which period the district has been subject more or less to Sind. The Talpur mirs succeeded the Kalhoras, and built a number of forts to overawe the people, who were lawless and addicted to robbery. On the British conquest of Sind in 1843 the greater part of the district was made over to Cutch, but in 1856 it was incorporated in the province of Sind. In 1859 a rebellion broke out, which was quickly suppressed.

THARANDT, a town of Germany, in the kingdom of Saxony, romantically situated on the Wilde Weisseritz, 9 m. S.W. of Dresden, on the Dresden-Reichenbach railway. Pop. (1905) 2967. It has a Protestant church, a hydropathic establishment, and the oldest academy of forestry in Germany (founded by Heinrich Cotta in 1811) with about sixty students. Tharandt is a favourite summer resort of the people of Dresden, one of its principal charms being the magnificent beech woods which surround it.

See Donner, *Tharandt* (Tharandt, 1890).

THARGELIA, one of the chief Athenian festivals in honour of the Delian Apollo and Artemis, held on their birthdays, the 6th and 7th of the month Thargelion (about the 24th and 25th of May). The name, which was derived by the ancients from *θέρειν τὴν γῆν* ("to reap the land"), is more probably connected with *τερσ-ῆναι* (cf. Lat. *torreo*, *tostus*), signifying the produce of the earth "baked" by the sun. Essentially an agricultural festival, the Thargelia included a purifying and expiatory ceremony. While the people offered the first-fruits of the earth to the god in token of thankfulness, it was at the same time necessary to propitiate him, lest he might ruin the harvest by excessive heat, possibly accompanied by pestilence. The purificatory preceded the thanksgiving service. On the 6th a sheep was sacrificed to Demeter Chloë on the Acropolis, and perhaps a swine to the Fates, but the most important ritual was the following. Two men, who were called *φαρμακοί* or *σύβακχοι*, the ugliest that could be found, were chosen to die, one for the men, the other (according to some, a woman) for the women. On the day of the sacrifice they were led round with strings of figs on their necks, and whipped on the genitals with rods of figwood and squills. When they reached the place of sacrifice on the shore, they were stoned to death, their bodies burnt, and the ashes thrown into the sea (or over the land, to act as a fertilizing influence). The whipping with squills and figwood was intended to stimulate the reproductive energies of the *φαρμακός*, who represented the god of vegetation, annually slain to be born again. It is agreed that an actual human sacrifice took place on this occasion, replaced in later times by a milder form of expiation. Thus at Leucas a criminal was annually thrown from a rock into the sea as a scapegoat: but his fall was checked by live birds and feathers attached to his person, and men watched below in small boats, who caught him and escorted him beyond the boundary of the city. Similarly, at Massilia, on the occasion of some heavy calamity (plague or famine), one of the poorest inhabitants volunteered as a scapegoat. For a year he was fed up at the public expense, then clothed in sacred garments, led through the city amidst execrations, and cast out beyond the boundaries. The ceremony on the 7th was of a cheerful character. All kinds of first-fruits were carried in procession and offered to the god, and, as at the Pyanepsia (or Pyanopsia), *εἰρεσιῶναι* (branches of olive bound with wool), borne by children, were affixed by them to the doors of the houses. These branches, originally intended as a charm to avert failure of the crops, were afterwards regarded as forming

[1] Stephanus of Byzantium gives it in a list of cities as a "Syrian town on the Euphrates," quoting from Theopompus, without noting that he has already referred to it under the name Amphipolis.

part of a supplicatory service. On the second day choruses of men and boys took part in musical contests, the prize for which was a tripod. Further, on this day adopted persons were solemnly received into the *genos* and *phratria* of their adoptive parents (see APATURIA).

Heuschkel, 1904–5).

THARRAWADDY, a town and district in the Pegu division of Lower Burma. The town has a station on the railway, 68 m. N.W. from Rangoon. Pop. (1901) 1643. The district has an area of 2851 sq. m. The Pegu Yoma range separates it from Toungoo district, and forms the water-parting between the rivers Irrawaddy and Sittang; there are also many small elevations. The Irrawaddy is the principal navigable river. Another important river is the Hlaing, which runs through the district from north to south, receiving from the east, through numerous channels, the drainage of the Pegu Yoma Mountains, which fertilizes the plain on its eastern bank. There are teak forests and fuel reserves, covering an area of 732 sq. m. Among the wild animals found in the mountains are elephant, rhinoceros, bison and various kinds of feathered game. The rainfall in 1905 was 91·65 in. Pop. (1901) 395,570, showing an increase of 17 per cent. in the decade. The railway runs through the centre of the district, with ten stations. The chief towns are Gyobingauk (6030) and Thonzè (6578). The staple crop is rice, but orchards and gardens are also common. The history of the district is identical with that of Henzada (*q.v.*). Tharrawaddy was formed in 1878 out of that portion of Henzada lying east of the Irrawaddy.

THARROS, an ancient town of Sardinia, situated on the west coast, on the narrow sandy isthmus of a peninsula at the north extremity of the Gulf of Oristano, now marked by the tower of S. Giovanni di Sinis. It was 12 m. W. of Othoca (Oristano) by the coast road, which went on northward to Cornus (a milestone of it is given in *Corp. Inscr. Lat.* x. 8009), and thence to Turris Libisonis. It was of Phoenician origin, but continued to exist in Roman times, as the inscriptions show, though they give but little information (Mommsen in *Corp. Inscr. Lat.* x. 822). It was destroyed by the Saracens in the 11th century. Scanty traces of Roman buildings may be seen, and an ancient road paved with large blocks of stone. A part of the site of the town is now invaded by the sea. The church of S. Giovanni di Sinis is a heavy building of the 8th (?) century A.D. originally cruciform, with a dome over the crossing; the transepts and dome are still preserved, but the nave with its two aisles is later. It is naturally built of materials from the old town. Close to it is a watch-tower and a spring of fresh water. The importance of Tharros may be inferred from the extent of its necropolis, which lies on the basaltic peninsula of S. Marco to the S.; on the summit of it are the remains of a *nuraghe*. Casual excavations are mentioned under the Spanish viceroys, but regular exploration only began in 1838, when the Roman tombs were examined. In 1850 Spano excavated many Phoenician tombs; they are rectangular or square chambers cut in the rock, measuring from 6 to 9 ft. each way, in which inhumation was the rule. The objects found—pottery, scarabs, jewelry, amulets, &c.—were of considerable interest. In 1851 Lord Vernon opened fourteen tombs, and after that the whole countryside ransacked the necropolis, without any proper records or notes being taken, and with great damage to the objects found. Some of these objects are in the museum at Cagliari, others in private collections, and many scarabs are in the British Museum, all of which by the coins found with them are dated later than the Roman occupation (*Catalogue of Gems*, London, 1888, pp. 13 sqq.). In 1885–86 regular excavations were made, the results of which may be seen in the museum at Cagliari. One tomb contained some fine gold ornaments, with Roman coins of the 1st to 3rd century A.D. (F. Vivanet in *Notizie degli Scavi*, 1886, 27; 1887, 46, 124). The objects, like those found at Sulcis, show considerable traces of Egyptian influence, but are probably all of Phoenician importation—the theory of the existence of Egyptian colonies in Sardinia being quite inadmissible. Some 3 m. to the N. is the church of S. Salvatore, with underground rock-cut chambers below it, used as a baptistery (?) by the early Christians, though the walls are decorated with paintings of a decidedly pagan nature. (T. As.)

THASOS, an island in the north of the Aegean Sea, off the coast of Thrace and the plain of the river Nestus (now the Kara-Su). The island was colonized at an early date by Phoenicians, attracted probably by its gold mines; they founded a temple of Heracles, which still existed in the time of Herodotus. Thasus, son of Phoenix, is said to have been the leader of the Phoenicians, and to have given his name to the island. In 720 or 708 B.C. Thasos received a Greek colony from Paros. In a war which the Parian colonists waged with the Saians, a Thracian tribe, the poet Archilochus threw away his shield. The Greeks extended their power to the mainland, where they owned gold mines which were even more valuable than those on the island. From these sources the Thasians drew great wealth, their annual revenues amounting to 200 or even 300 talents. Herodotus, who visited Thasos, says that the best mines on the island were those which had been opened by the Phoenicians on the east side of the island facing Samothrace. The place was important during the Ionian revolt against Persia. After the capture of Miletus (494 B.C.) Histiaeus, the Ionian leader, laid siege to Thasos. The attack failed, but, warned by the danger, the Thasians employed their revenues to build war ships and strengthen their fortifications. This excited the suspicions of the Persians, and Darius compelled them to surrender their ships and pull down their walls. After the defeat of Xerxes the Thasians joined the Delian confederacy; but afterwards, on account of a difference about the mines and marts on the mainland, they revolted. The Athenians defeated them by sea, and, after a siege that lasted more than two years, took the capital, Thasos, probably in 463, and compelled the Thasians to destroy their walls, surrender their ships, pay an indemnity and an annual contribution (in 449 this was $2\frac{1}{2}$ talents, from 445 about 30 talents), and resign their possessions on the mainland. In 411 B.C., at the time of the oligarchical revolution at Athens, Thasos again revolted from Athens and received a Lacedaemonian governor; but in 407 the partisans of Lacedaemon were expelled, and the Athenians under Thrasybulus were admitted. After the battle of Aegospotami (405 B.C.), Thasos again fell into the hands of the Lacedaemonians under Lysander who formed a decarchy there; but the Athenians must have recovered it, for it formed one of the subjects of dispute between them and Philip II. of Macedonia. In the embroilment between Philip III. of Macedonia and the Romans, Thasos submitted to Philip, but received its freedom at the hands of the Romans after the battle of Cynoscephalae (197 B.C.), and it was still a "free" state in the time of Pliny. After a period of Latin occupation, it was captured by the Turks in 1462; it was given by the Sultan Mahmud II. to Mehemet Ali of Egypt, and still remains the property of the khedive. Thasos, the capital, stood on the north side of the island, and had two harbours, one of which was closed. Archilochus described Thasos as "an ass's backbone crowned with wild wood," and the description still suits the mountainous island with its forests of fir. The highest mountain, Ipsario, is 3428 ft. high. Besides its gold mines, the wine, nuts and marble of Thasos were well known in antiquity. The mines and marble quarries are no longer worked; and the chief exports are now fir timber for shipbuilding, olive oil, honey and wax. The imports consist of manufactured goods, beasts of burden and corn, for the island is too mountainous to grow enough corn for the inhabitants.

The population, distributed in ten villages, is estimated at

8000. The people are Greek Christians, and do not differ in appearance from the inhabitants of the other Greek islands. The villages are mostly situated at some distance from the sea; for the island suffered from pirates. Even in the early part of the 19th century sentinels stood on duty night and day, and at a signal of alarm the whole population, including the Turkish aga himself, used to hide in the woods.

For a description of the island and its remains of antiquity, see A. Conze, *Reise auf den Inseln des thrakischen Meeres* (Hanover, 1860); for inscriptions see *Inscr. Gr.* xii. 8; the island is fully described by J. ff. Baker-Penoyre in *Journal Hell. Stud.* xxix. (1909).

THATCH (O.E. *thaec*; the word is common to many Teutonic languages in the sense of "roof," "cover"; cf. Du. *dak*, Ger. *Dach*; from Du. *dekken* comes "deck"; the Indo-European root is *stag*, whence Gr. *στέγος*, roof, Lat. *tegere*, to cover; the French equivalent is *chaume*), the material employed sometimes for roofs in the place of tiles or slates; it consists of wheat straw, of which several layers are required, to the depth of from 12 to 14 in., or even extending to 18 in. Unthreshed straw is said to last from twenty-five to thirty years, and is easily repaired. In Norfolk the reeds of marshland are employed, and they constitute a durable thatch lasting from thirty to forty years or more. Thatched roofs are not now allowed in London or other towns and their vicinity, but if saturated with a solution of lime the thatch is said to be incombustible. It forms an extremely good roof, warm in winter and cool in summer.

THATON, a town and district in the Tenasserim division of Lower Burma. The town is situated below a hill range, 10 m. from the sea. It was formerly the capital of the Talaing kingdom and a sea-port. Pop. (1901) 14,342. The district has an area of 5079 sq. m.; pop. (1901) 343,510, showing an increase of 29 per cent. in the decade. It was formerly a subdivision of Amherst district, but was formed in 1895 out of part of that and of Shwegyin district, which has now ceased to exist. The staple crop is rice, but a good deal of tobacco also is grown. The railway from Pegu to Martaban, recently opened, passes through this district and is calculated to increase its prosperity and population.

THAXTER, CELIA (1836–1894), American poet, was born at Portsmouth, New Hampshire, on the 29th of June 1836. Her father, Thomas B. Laighton, became offended with some of his associates in state politics, and retired about 1841 to the barren and isolated Isles of Shoals, ten miles off Portsmouth, where for about ten years he was keeper of the White Island lighthouse; and his daughter's girlhood was therefore spent in marine surroundings, which coloured the best of the verse she afterwards wrote. Her poems, mainly in lyrical form, deal with the beacon-light, the sea-storm, the glint of sails, the sandpiper, the flower among the rocks, &c., in characteristic and sympathetic fidelity. She also wrote prose sketches of life and scenery, *Among the Isles of Shoals* (1873); stories and poems for children, and letters; besides a book about floriculture, *An Island Garden* (1894). In 1896 appeared a complete edition of her poems, edited by Sarah Orne Jewett. She married in 1851 Levi L. Thaxter (d. 1884), a devoted student of Robert Browning's poetry, and spent most of her life on Appledore, one of the Isles of Shoals, where she died on the 26th of August 1894. Her son Roland Thaxter (b. 1858), a well-known cryptogamic botanist, became professor of botany at Harvard in 1891.

THAYER, ABBOTT HANDERSON (1849–), American artist, was born at Boston, Massachusetts, on the 12th of August 1849. He was a pupil of J. L. Gérôme at the École des Beaux Arts, Paris, and became a member of the Society of American Artists (1879), of the National Academy of Design (1901), and of the Royal Academy of San Luca, Rome. As a painter of portraits, landscapes, animals and the ideal figure, he won high rank among American artists. Among his best-known pictures are, "Virgin Enthroned," "Caritas," "In Memoriam, Robert Louis Stevenson," and "Portrait of a Young Woman"; and he did some decorative work for the Walker Art Building, Bowdoin College, Maine. Thayer is also well known as a naturalist. He developed a theory of "protective coloration" in animals (see Colours of Animals), which has attracted considerable attention among naturalists. According to this theory, "animals are painted by nature darkest on those parts which tend to be most lighted by the sky's light, and vice versa"; and the earth-brown of the upper parts, bathed in sky-light, equals the skylight colour of the belly, bathed in earth-yellow and shadow.

See his article, "The Law which underlies Protective Coloration," in the *Annual Report* of the Smithsonian Institution for 1897 (Washington, 1898); and *Concealing Coloration in the Animal Kingdom* (New York, 1910), a summary of his discoveries, by his son, Gerald H. Thayer.

THAYER, JAMES BRADLEY (1831–1902), American legal writer and educationist, was born at Haverhill, Massachusetts, on the 15th of January 1831. He graduated at Harvard College in 1852, and at the Harvard Law School in 1856, in which year he was admitted to the bar of Suffolk county and began to practise in Boston. In 1873–83 he was Royall professor of law at Harvard; in 1883 he was transferred to the professorship which after 1893 was known as the Weld professorship and which he held until his death on the 14th of February 1902. He took an especial interest in the historical evolution of law.

He wrote: *The Origin and Scope of the American Doctrine of Constitutional Law* (1893); *Cases on Evidence* (1892); *Cases on Constitutional Law* (1895); *The Development of Trial by Jury* (1896); *A Preliminary Treatise on Evidence at the Common Law* (1898), and a short life of John Marshall (1901); and edited the twelfth edition of Kent's *Commentaries* and the *Letters of Chauncey Wright* (1877), and *A Westward Journey with Mr Emerson* (1884).

THAYER, JOSEPH HENRY (1828–1901), American biblical scholar, was born at Boston on the 7th of November 1828. He studied at the Boston Latin School, and graduated at Harvard in 1850. Subsequently he studied theology at the Harvard Divinity School, and graduated at Andover Theological Seminary in 1857. He preached in Quincy, and in 1859–64 in Salem, Massachusetts, and in 1862–63 was chaplain of the 40th Massachusetts Volunteers. He was professor of sacred literature in Andover Seminary in 1864–82, and in 1884 succeeded Ezra Abbot as Bussey professor of New Testament criticism in the Harvard Divinity School. He died on the 26th of November 1901, soon after his resignation from the Bussey professorship. He was a member of the American Bible Revision Committee and recording secretary of the New Testament company. His chief works were his translation of Grimm's *Clavis Novi Testamenti* (1887; revised 1889) as *A Greek-English Lexicon of the New Testament*, and his New Testament bibliography (1890).

THAYETMYO, a town and district in the Minbu division of Upper Burma. The town is situated on the right bank of the Irrawaddy, opposite Allanmyo. Pop. (1901) 15,824. The cantonment contains the wing of a British battalion and a native regiment. It enjoys a high reputation for healthiness. There is a special industry of silver work.

The district has an area of 4750 sq. m.; pop. (1901) 239,706, showing a decrease of 4 per cent. in the decade. The total rainfall in 1905 was 41·30 in. On the west is the Arakan Yoma range, and on the east the Pegu Yomas; and the face of the country, where it does not rise into mountains, is everywhere broken by low ranges of hills, many of which are barren and destitute of all vegetation. The greater part of the district is wooded, and the Yomas east and west are covered with forests, now mostly preserved. The chief river is the Irrawaddy, which traverses Thayetmyo from north to south. The drainage finds its way to the Irrawaddy by three main streams (the Pwon, Ma-htún and Ma-de) on the west, and by two (the Kye-ni and Hput) on the east. Several salt and hot springs occur in many localities; petroleum is also found, and extensive lime quarries exist a few miles south of Thayetmyo. The principal wild animals are elephants, rhinoceros, tigers, leopards, black bears and wild hog. Silver pheasants and partridges are found in large numbers, especially in the mountains. The chief products are rice, cotton, oil-seeds and tobacco; cutch is also very abundant, and the manufacture of the dye-stuff is carried on extensively. Coal has been found in the district, and earth oil-wells exist, but neither coal nor oil has yet been extracted in any quantity. There are 403 sq. m. of reserved forest. Three oil-wells were sunk in 1883 at Pedaukpin, but they were found unprofitable and abandoned.

On the annexation of Pegu by the British in 1852–53, Thayetmyo was formed into a subdivision of Prome district; and in 1870 it was erected into a separate jurisdiction and placed under a deputy-commissioner. It was formerly in the Irrawaddy division of Lower Burma, but was transferred to Upper Burma for administrative purposes in 1896.

THEATRE (*θέατρον*, "a place for seeing," from *θεᾶσθαι*), a building specially devised for dramatic representations. The drama arose from the choric dances in honour of Dionysus, which were held in a circular dancing-place (*ὀρχήστρα*, Lat. *orchestra*) in his precinct at the foot of the Acropolis at Athens. When the leader of the chorus held a dialogue with the remaining *choreutae* he mounted the table which stood beside the altar of Dionysus in the centre of the *orchestra*; but as the number of actors and the importance of the dialogue increased, it became necessary to erect a platform at the side of the dancing-place and a booth in which the performers could change their dresses and masks. At the same time temporary wooden stands (*ἴκρια*) were set up for the spectators, who no longer ranged themselves around the whole ring, but only on the slope of the Acropolis, facing southward. We are told that the collapse of the *ἴκρια*, in 499 B.C. led to the erection of a permanent theatre; this was not, however, a stone building. Embankments were made for the support of the spectators' benches: the stage buildings were of wood, and, although some traces of a stone theatre belonging to the end of the 5th century have been pointed out, the "theatre of Dionysus," whose remains may still be seen (Pl. I. and II.), is in the main a work of the 4th century. It was completed soon after 340 B.C. under the administration of the statesman and financier Lycurgus. Alterations were made in the stage-buildings in the Hellenistic period, under Nero, and again in the 3rd century A.D. Although the prototype of Greek theatres, it is not the most perfectly preserved. Amongst those of purely Greek design the most typical is that of Epidaurus (Pl. I.), which was built in the latter part of the 4th century B.C. by Polyclitus the Younger. The largest known to Pausanias was that of Megalopolis, excavated by the British School at Athens in 1889–91, in which the stage buildings were replaced by the Thersilion, a large council-chamber. Others of importance for the study of the ancient theatre have been excavated at Delos, Eretria, Sicyon and Oropus. None of these, of course, is contemporary with the classical period of the Greek drama, and their stone stage-fronts belong to the Hellenistic period.

In Asia Minor we find a type of theatre (belonging to a somewhat later date) with a broader, lower and deeper stage; and

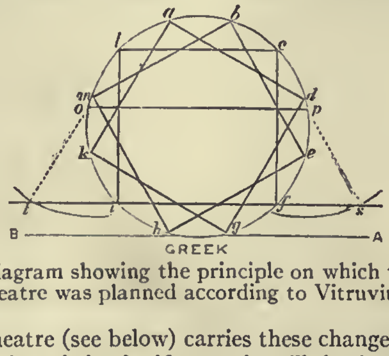

Fig 1.—Diagram showing the principle on which the Greek theatre was planned according to Vitruvius.

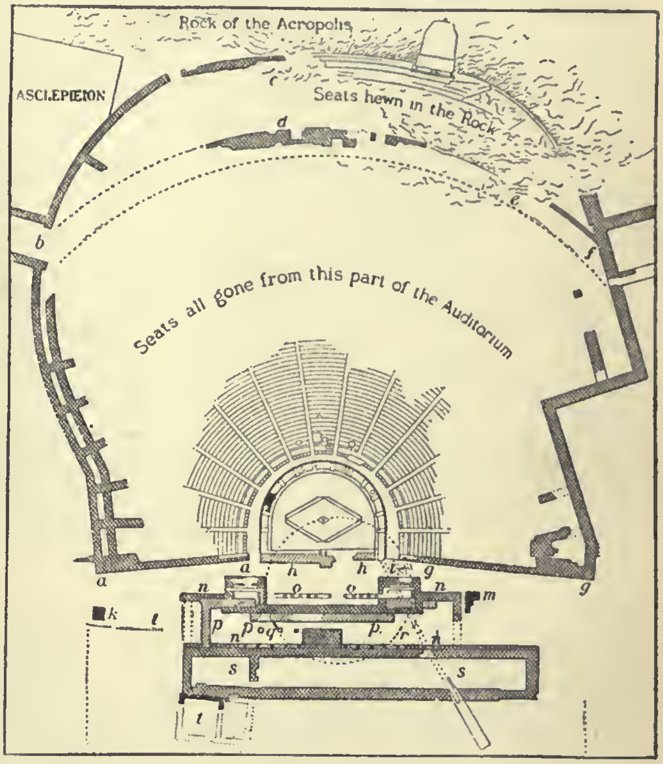
the Roman theatre (see below) carries these changes still further. Before discussing their significance it will be best to describe the parts of the ancient theatre, the fullest account of which is to be found in the fifth book of Vitruvius (written in the Augustan period).

Its three main divisions were the auditorium (Lat. *cavea*; it had no technical name in Greek), the orchestra, and the stage buildings (*σκηνή*, literally "tent" or "booth" Lat. *scena*). As the orchestra was the germ of the theatre, so it determined its shape, and in the Greek theatre preserved its circular form in many instances (as at Epidaurus). In the scheme of proportions given by Vitruvius, however (see fig. 1, which carries its own explanation), a segment (*ihgf*) was cut off by the stage-front (*προσκήνιον*, *proscenium*). The auditorium was divided by flights of seats into wedge-shaped blocks (*κερκίδες*, *cunei*) and also longitudinally by a gangway (*διάζωμα*, *praecinctio*). In Greece the slope of a hill was always chosen for the auditorium and furnished with stone seats in tiers like steps. The slope of the Acropolis faces south, which (as Vitruvius points out) was the worst aspect for the spectators; but this was unavoidable for religious reasons, since the performances had to be held in the precinct of Dionysus. At Athens the inner boundary was a semicircle with the ends prolonged in parallel straight lines, which gave the spectators in the wings a better view of the stage than that obtainable in those theatres where (according to the Vitruvian rule) the boundary was segmental. At Epidaurus



Scale —— 20 yards.

ab, double western wall.
bc, single wall.
aa, *gg*, walls terminating wings of auditorium.
b, *f*, entrances.
c, the "katatome" (where the rock of the Acropolis was met by the walls).
d, *e*, diazoma.
fg, eastern boundary wall.
hh, front wall of Neronian stage.
i, fragment 5th-century orchestra.
klm, ancient masonry (? of supporting walls).
nn, oldest stage buildings.
oo, stone proscenium (1st or 2nd century B.C.).
p, foundations of Neronian side wings.
qr, fragments 5th-century orchestra.
s, 4th-century portico.
t, old Dionysus temple.

a compromise was effected by prolonging the ends of the semicircle as segments of a curve with a longer radius. The best seats were in the lowest row; at Athens this was formed by a series of marble thrones assigned to various priests or officials whose titles may be read on those (60 out of 67) which are now preserved. The priest of Dionysus occupied the central throne. In some theatres benches with backs took the place of separate thrones. The right of sitting in reserved places was called *προεδρία*.

The orchestra, which was separated from the auditorium by a gutter and kerb and generally paved with slabs, contained an altar of Dionysus called the *θυμέλη*, whence the choral or musical contests which took place in it were called *ἀγῶνες θυμελικοί*. At Athens this altar stood in the middle of a lozenge-shaped marble pavement. In a few theatres subterranean passages have been found, leading from the stage-buildings to the middle of the orchestra, which may be supposed to have been used for the appearance of actors (*e.g.* as ghosts) in the orchestra: they do not exist, however, at Athens or Epidaurus, so that no general argument can be founded on their remains.

The stage buildings of the earliest Greek theatres have been destroyed save for the foundations and architectural fragments, and the interpretation of their remains presents a difficult problem. Whether built on level ground or (as at Sicyon and elsewhere) excavated in rock or earth they consisted of a rectangular structure two stories high, usually with projecting side wings (*παρασκήνια*). Between these wings was the *προσκήνιον* (stage), which at Athens and indeed in all early theatres was built of wood, but was afterwards reconstructed in stone, with a front formed by a row of columns from 10 to 13 ft. high; its depth varied from 8 to 10½ ft. It has been argued by Dörpfeld that the *προσκήνιον* was not a stage, but a background, which could be characterized as a palace, temple, &c., by means of painted *πίνακες* set up in the intervals between the columns, and that throughout the history of the Greek drama actors as well as chorus performed in the orchestra. This theory has been supported by arguments drawn from passages of the classical dramatists, which seem to imply that actors and chorus were on the same level, and by *a priori* considerations regarding the unfitness of so high and narrow a platform, unconnected with the orchestra by stairs (except such temporary wooden steps as may have left no trace in extant remains), for a stage. But these arguments are outweighed by the positive testimony of ancient writers and inscriptions that the actors in the Greek drama mounted on a platform (*ὀκρίβας*) which was also called the *λογεῖον* ("speaking-place"), and the description of the Greek theatre by Vitruvius, who tells us that the *λογεῖον* (Lat. *pulpitum*) was narrower than that of the Roman theatre, and was from 10 to 12 ft. high. Moreover the background afforded by the Hellenistic *προσκήνια* would have been diminutive in its proportions—it must be remembered that Greek actors stood some 6 ft. 6 in. high when wearing the *cothurnus* and tragic mask—and quite unlike a palace or temple. They never have more than one doorway in the centre, though Vitruvius prescribes three, and in some theatres (where the stage-buildings were partly excavated) there are no rooms at the back of them, but either virgin rock or earth. We may therefore dismiss Dörpfeld's theory: but it is more than probable that the wooden stage of the 5th century B.C. was much lower than that of Hellenistic times, when the chorus had either disappeared from dramatic performances or performed musical interludes unconnected with the action of the play. Horace, in fact, says of Aeschylus: "Aeschylus . . . modicis instravit pulpita tignis," and doubtless preserves a fragment of genuine tradition. When chorus and actors came into contact, wooden steps could be used, and that such were employed even in the later drama is proved by the evidence of South Italian vase-paintings which represent the Phylakes or burlesques popular at Tarentum.

The façade of the *σκηνή* furnished an architectural background, and this was supplemented by painted scenery, which, according to Aristotle, was introduced by Sophocles: Vitruvius, however, tells us that the first scene-painter, Agatharchus, worked for Aeschylus. In their days the *σκηνή* was, of course, a mere booth. Changes of scene were very rare—there are only two in the extant classical tragedies—and were brought about by the use of revolving prisms (*περίακτοι*). Other appliances used in the Greek drama were the *ἐκκύκλημα*, a low platform on rollers which was pushed forward in order to show an action supposed to take place in the interior of the *σκηνή* (the scene in a Greek play was always laid in the open air), and the *μηχανή*, a crane by which an actor representing a god could be suspended in mid-air (hence the phrase *deus ex machina*). In the upper part of the *σκηνή* was a balcony called the *διστεγία* ("second story"), and at the top a narrow platform called the *θεολογεῖον*, upon which gods supposed to be stationary in heaven could appear. Ghosts ascending from the underworld mounted the *χαρώνιοι κλίμακες*, whose position is uncertain. The *βροντεῖον* was a machine for imitating thunder by means of stones rolled in metal jars. It is far from certain whether a drop-scene was used in the classical period of the Greek drama; in later times and in the Roman theatre a curtain (*αὐλαία*, Lat. *aulaea*, *siparium*) was let down into a narrow slit in front of the stage before the play began and drawn up at the end.

It has been mentioned above that in the later Hellenistic theatres the stage was made broader, lower and deeper, and in the Roman theatre, the principle of whose construction, as explained by Vitruvius, is illustrated by fig. 3, the orchestra is reduced to a semicircle (*acd*). The line *ef* is that of the background (*scenae frons*) and its limits are those of the *cavea* or auditorium.

The Romans, by their use of the arch in construction and also of concrete for vaulting, were enabled to erect theatres on level ground, such as the Campus Martius at Rome, where an elaborate structure, usually in three stories of arcades,[1] took the place of the natural hill-slope of Greek theatres. The Roman theatre thus became an organic whole; the auditorium and stage-buildings were structurally connected, and the orchestra was entered from the wings, not by open passages (*πάροδοι*) as in Greece, but by vaulted corridors. The orchestra was no longer used for the performances (whether dramatic, musical or merely spectacular), but was reserved for senators and other persons of distinction. Hence (as Vitruvius points out) arose the necessity for lowering and enlarging the stage. It is hard to say when this change was made or at what date it was first introduced into Italy (if it did not originate in the west). The larger of the two theatres at Pompeii dates from the Hellenistic period, but was thrice reconstructed, and it is not clear to what date we are to assign the low stage of Roman pattern; possibly it belongs to the earliest period of the Roman colony at Pompeii founded by Sulla (B.C. 80). The theatre of Pompey (see below) is said by Plutarch to have been copied from that of Mytilene, which suggests that the Roman theatre was derived from a late Greek model; and this is made probable by the existence of transitional forms.

During the Republican period the erection of permanent theatres with seats for the spectators was thought to savour of Greek luxury and to be unworthy of the stern simplicity of the Roman citizens. Thus in 154 B.C. Scipio Nasica induced the senate to demolish the first stone theatre which had been begun by C. Cassius Longinus ("tanquam inutile et nociturum

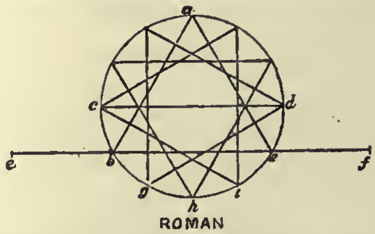

FIG. 3.—Diagram showing the principle on which the Roman theatre was planned according to Vitruvius.

publicis moribus," Liv. *Epit.* 48). Even in 55 B.C., when Pompey began the theatre of which remains still exist in Rome, he thought it wise to place a shrine to Venus Victrix at the top of the cavea, as a sort of excuse for having stone seats below it—the seats theoretically serving as steps to reach the temple. This theatre, which was completed in 52 B.C., is spoken of by Vitruvius as "the stone theatre" *par excellence*: it is said by Pliny to have held 40,000 people.[2] It was also used as an amphitheatre for the bloody shows in which the Romans took greater pleasure than in the purer intellectual enjoyment of the drama. At its inauguration 500 lions and 20 elephants were killed by gladiators. Near it two other theatres were erected, one begun by Julius Caesar and finished by Augustus in 13 B.C., under the name of his nephew Marcellus,[3] and another built about the same date by Cornelius Balbus (Suet. *Aug.* 29; Pliny, *H. N.* xxxvi. 59). Scanty remains exist of this last theatre, but the ruins of the theatre of Marcellus are among the most imposing of the buildings of ancient Rome.

A long account is given by Pliny (*H. N.* xxxvi. 5 and 114) of a most magnificent temporary theatre built by the aedile M. Aemilius Scaurus in 58 B.C. It is said to have held the incredible number of 80,000 people, and was a work of the most costly splendour. Still less credible is the account which Pliny gives (*H. N.* xxxvi. 116) of two wooden theatres built by C. Curio in 50 B.C., which were made to revolve on pivots, so that the two together could form an amphitheatre in the afternoon, after having been used as two separate theatres in the morning.

All Roman provincial towns of any importance possessed at least one theatre; many of these are partly preserved. On

[1] Vitruvius prescribes for the Roman theatre a portico running round the interior of the auditorium on the level of the topmost row of seats; remains of such a portico (or, as at Aspendus, of a series of arcades) can sometimes be traced.

[2] Huelsen has shown that this statement is exaggerated, and estimates the number of spectators at 9000 to 10,000.

[3] According to Livy (xl. 51), the theatre of Marcellus was built on the site of an earlier one erected by Aemilius Lepidus.

INTERIOR OF THEATRE, ORANGE.

Pl. II. will be found reproductions of two of the most important—that of Aspendus in Pamphylia, which illustrates the Eastern type showing Hellenistic influence, and that of Arausio (Orange) in South Gaul. Covered theatres were sometimes built, whether on account of climatic conditions (as at Aosta) or more commonly for musical performances. These latter were generally called *Odea* (Gr. *ᾠδεῖον*, a place for singing). The best preserved is the Odeum of Herodes Atticus, at the south-west angle of the Athenian Acropolis, which has a semicircular orchestra. It was built in the reign of Hadrian by Herodes Atticus,[1] a very wealthy Greek, who spent enormous sums in beautifying the city of Athens, in honour of his wife Regilla. Its cavea, which is excavated in the rock, held about 6000 people; it was connected with the great Dionysiac theatre by a long and lofty porticus or stoa, of which considerable remains still exist, probably a late restoration of the stoa built by Eumenes II. of Pergamum. It was also a common practice to build a small covered theatre in the neighbourhood of an open one, where performances might take place in bad weather. We have an example of this at Pompeii. The Romans used scenery and stage effects of more elaboration than was the custom in Greece. Vitruvius (iii. 7) mentions three sorts of movable scenery:—(1) for the tragic drama, façades with columns representing public buildings; (2) for comic plays, private houses with practicable windows and balconies;[2] and (3) for the satyric drama, rustic scenes, with mountains, caverns and trees.

Bibliography.—By far the fullest account of the Greek theatre is given in Dörpfeld and Reisch, *Das griechische Theater* (Athens, 1896). Its main thesis is, however, rejected by many archaeologists on the grounds stated above. Puchstein, *Die griechische Bühne*, endeavours to prove that a stone theatre was built at Athens in the 5th century B.C., and that the proscenium usually supposed to be Hellenistic dates from the time of Lycurgus (above). For English readers the best account of the Greek theatre is to be found in A. E. Haigh's *Attic Theatre* (3rd ed., revised by A. W. Pickard-Cambridge, 1907), where a bibliography of the voluminous literature of recent times is given. Albert Müller's *Lehrbuch der griechischen Bühnenaltertümer* (Freiburg, 1886) is indispensable to the student. For the Roman theatre reference may be made to Durm, *Baukunst der Römer*, ed. 2, pp. 645 ff.

(J. H. M.; H. S. J.)

The Modern Theatre

During the middle ages miracle plays with sacred scenes were the favourite kind of drama; no special buildings were erected for these, as they were represented either in churches or in temporary booths. In the 16th century the revival of the secular drama, which, in the reign of Elizabeth, formed so important a part of the literature of England, was carried on in tents, wooden sheds, or courtyards of inns, mostly by strolling actors of a very low class. It was not till towards the close of the century that a permanent building was constructed and licensed for dramatic representations, under the management of Shakespeare and Burbage.

The first building specially erected in London for dramatic purposes was built in 1576–77 by the actor James Burbage. It was constructed of timber, and stood in Holywell Lane, Shoreditch, till 1598, when it was pulled down; it was known as "The Theatre" *par excellence*. Of almost equally early date was the "Curtain" theatre, also in Shoreditch; so called from the plot of ground, known as "The Curten," on which it stood. It probably continued in use till the general closing of theatres by order of the parliament in 1642. The "Globe" theatre, famous for its association with Shakespeare, was built by James Burbage, who used the materials of "The Theatre," in the year 1599. Its site was in Southwark, in the Bankside, near the "Bear Gardens." It was an octagonal structure of wood, with lath and plaster between the main framework. It was burnt in 1613, rebuilt, and finally pulled down and its site built over in 1644. Its name was derived from its sign of Atlas supporting the globe. Near it were two less important theatres, "The Rose," opened in 1592 by Henslowe, and "The Swan" (see below), opened in 1598 and partly owned also by Henslowe; like the Globe, the latter was an octagonal wood-and-plaster building. The "Blackfriars" theatre, another of the Burbages' ventures, was built in 1596, near the old Dominican friary. The "Fortune" theatre was built by Edward Alleyn, the actor, in 1599, at a cost, including the site, of £1320. It stood between Whitecross Street and Golding Lane. It stood as late as 1819, when a drawing of it was given by Wilkinson (*Londina illustrata*, 1819). The "Red Bull" theatre was probably originally the galleried court of an inn, which was adapted for dramatic purposes towards the close of Elizabeth's reign. Other early theatres were the "Hope" or "Paris Garden" theatre, the "Whitefriars" and "Salisbury Court" theatres, and the "Newington" theatre. A curious panoramic view of London, engraved by Visscher in 1616, shows the Globe, the Hope and the Swan theatres.

The plan of the first English theatres appears to have had no connexion with those of classical times, as was the case in Italy: it was evidently produced in an almost accidental way by the early custom of erecting a temporary platform or stage in the middle of the open courtyard of an inn, in which the galleries all round the court formed boxes for the chief spectators, while the poorer part of the audience stood in the court on all sides of the central stage. Something similar to this arrangement, unsuitable though it now seems, was reproduced even in buildings, such as the Globe, the Fortune and the Swan, which were specially designed for the drama. In these and other early theatres there was a central platform for the stage, surrounded by seats except on one side, where there was a "green-room" or "tireynge-howse." The upper galleries or boxes completely surrounded the stage, even the space over the green-room being occupied by boxes. This being the arrangement, it is easy to see why the octagonal plan was selected in most cases, though not in all—the Fortune theatre, for example, was square. An interesting specification and contract for the building of the Fortune theatre (see below) is printed by Halliwell-Phillipps (*op. cit. infra*, p. 164). In all its details the Fortune is specified to be like the Globe, except that it is to be square in plan, and with timbers of heavier scantling. The walls are to be of wood and plaster, the roof tiled, with lead gutters, the stage of oak, with a "shadow" or cover over it, and the "tireynge-howse" to have glazed windows. Two sorts of boxes are mentioned, viz., "gentlemen's roomes" and "twoopennie roomes." A woodcut showing this arrangement of the interior is given in a collection of plays edited by Kirkman in 1672. The vexed question of the construction of these theatres has been much discussed in recent years. In 1888 a drawing of the Swan theatre (fig. 4), apparently copied from a rough drawing in a London letter from the traveller Johannes de Witt, was discovered by Dr Karl Gaedertz in a manuscript volume in the Utrecht University library, consisting of the commonplace book of Arend van Buchell (1565–1641). While undoubtedly authentic, and probably broadly accurate, this copied sketch cannot be accepted, however, as giving the regular or typical plan of the contemporary theatre, as in some respects it does not fulfil the known conditions of the stage. What that typical plan was, if (as is probable) one actually existed, has led to much learned conjecture and great difference of opinion as regards the details required by the interpretation of contemporary stage directions on the necessities of the action in contemporary drama. The ingenious reconstruction (fig. 5), drawn by W. H. Godfrey in 1907, of the Fortune theatre, following the builder's specification, appears to approach very nearly to satisfying all the requirements. (See "The Elizabethan Stage," in the *Quarterly Review* (London), April 1908.)

In the 16th and 17th centuries a favourite kind of theatrical representation was in the form of "masques," with processions of grotesquely attired actors and temporary scenic effects of great splendour and mechanical ingenuity. In the reigns of James I.

[1] This theatre was not begun when Pausanias wrote his book *Attica*, and was complete when he wrote the *Achaica* (see Paus. vii. 20). It is illustrated in *Mon. Inst.* vi., plate 16.

[2] These are shown on Graeco-Roman vases of the latest type, with paintings of burlesque parodies of mythological stories.

and Charles I., Ben Jonson and the architect Inigo Jones worked together in the production of these "masques," Jonson writing the words and Inigo Jones devising the scenic effects, the latter being very costly and complicated, with gorgeous buildings, landscapes, and clouds or mountains, which opened to display mimic deities, thrown into relief by coloured lights. These masques were a form of opera, in which Ben Jonson's words were set to music. Ben Jonson received no more for his libretto than Inigo Jones did for his scenic devices, and was not unnaturally annoyed at the secondary place which he was made to occupy: he therefore revenged himself by writing severe satires on Inigo Jones and the system which placed the literary and mechanical parts of the opera on the same footing. In an autograph MS. which still exists this satirical line occurs—"Painting and carpentry are the soul of masque" (see Cunningham, *Life of Inigo Jones*, London, 1848).

In Italy, during the 16th century, the drama occupied a more important position, and several theatres were erected, professedly on the model of the classic theatre of Vitruvius. One of these, the Teatro Olimpico at Vicenza, still exists; it was designed by Palladio, but was not completed till 1584, four years after his death. It has an architectural scena, with various orders of columns, rows of statues in niches, and the three doors of the classic theatre; but the whole is painted with strong perspective effects which are very unclassical in spirit. Scamozzi, Palladio's pupil, who completed the Teatro Olimpico,

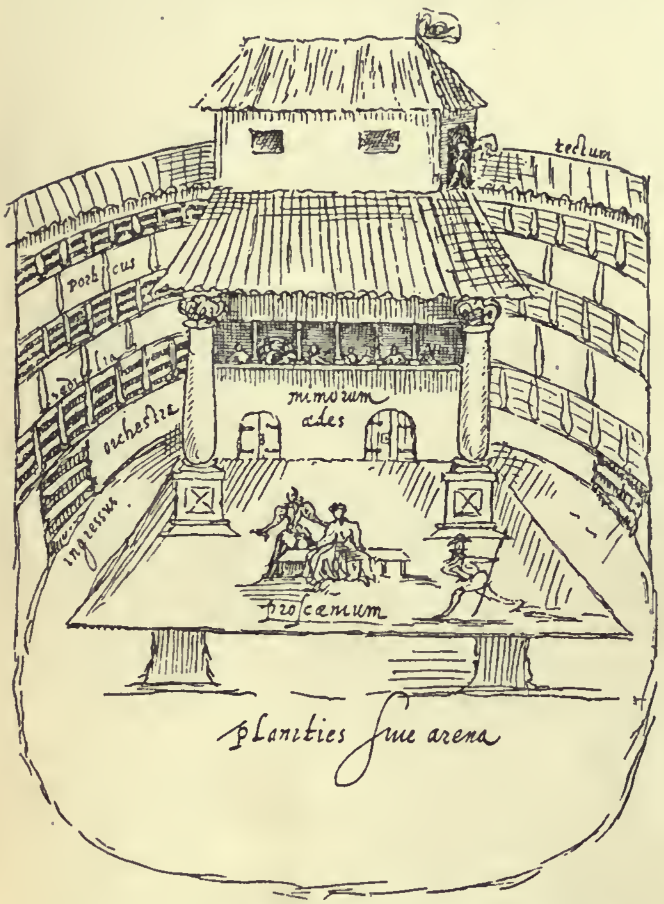

Fig. 4.—Swan Theatre; from Sidney Lee's *Life of William Shakespeare*, by permission.

built another pseudo-classical theatre in 1588 at Sabbionetta for the duke Vespasiano Gonzaga, but this does not now exist.

In France the miracle play developed into the secular drama rather earlier than in England. In the reign of Louis XI., about 1467, the "Brothers of the Passion" had a theatre which was partly religious and partly satirical. In the 16th century Catherine de' Medici is said to have spent incredible sums on the dresses and scenery for the representation of the Italian ballet; and in the middle of the 17th century the regular opera was introduced at Paris.

At the end of the 18th century the theatres of San Carlo at Naples, La Scala at Milan, and La Fenice at Venice were the finest in Europe; all these were rebuilt in the 19th century,

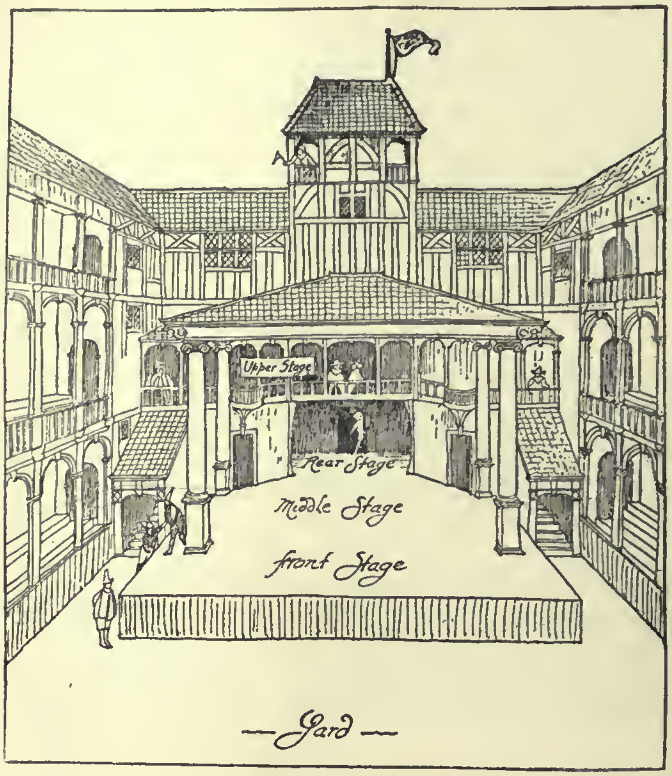

Fig. 5.—The Fortune Theatre; restoration of Walter H. Godfrey.

but have been eclipsed by the later theatres of London, Paris, St Petersburg and other great cities of Europe and America, both in size and architectural splendour.

Authorities.—Much valuable information about the early theatres of London is given by Wilkinson, *Londina illustrata* (1819), in which are engravings of some of them. See also Collier, *Hist. of Dramatic Poetry* (1879); Halliwell-Phillipps, *Life of Shakespeare* (1883); R. Lowe, *Life of T. Betterton;* Malone, *History of the Stage* (1790), republished by Boswell in 1821; the publications of the New Shakspere Society; the Ninth Report of the Historical MSS. Commission; and a series of articles on early London theatres, by T. F. Ordish, in *The Antiquary*, vols. xi., xii. and xiv. (1885–86). On the problems connected with the construction of the Elizabethan theatre, see Dr Cecil Brodmeier, *Die Shakespeare-Bühne nach den alten Bühneranweisungen* (Weimar, 1904); Dr Paul Mönkemeyer, *Prolegomena einer Darstellung der Englischen Volksbühne zur Elizabeth und Stuart Zeit* (Leipzig, 1905); Dr Richard Wegener, *Die Buhneneinrichtung des Shakespeareschen Theaters nach dem zeitgenossischen drama* (Halle, 1907); George F. Reynolds, *Some Principles of Elizabethan Staging* (Chicago University, 1905); E. K. Chambers, "The Stage of the Globe," in vol. x. of the Stratford *Shakespeare* (1904); Victor E. Albright, *A Typical Shakesperian Stage* (New York, 1908). (J. H. M.; H. Ch.)

Modern Stage Mechanism

A movement known as "Stage Reform" originated in Austria about 1880, with the primary object of encouraging the greatest possible imitation of nature in the presentation of opera and drama. The rudiments of art as understood by painters, sculptors, architects and the cultured public of the day were to be applied to the stage, and a true scenic art was to take the place of the nondescript mounting previously given. To facilitate the efforts of the scenic artist, the fullest application of modern science, notably of mechanics and hydraulics, and the introduction of up-to-date methods of lighting were considered essential. The numerous fatal conflagrations which had originated on the stage caused the question of protection from fire to be closely associated with this movement, and the enterprise made great headway, more particularly on account of the protective measures against fire proposed soon after the burning of the old Ring Theatre at Vienna. The movement gradually developed throughout Austria and Germany and spread beyond the frontiers of these countries. Concurrently, independent movements originated elsewhere, and from 1885 to 1895 a transitional period may be said to have existed for the stage, both in Europe and in the United States, but by the close of the 19th century the necessity for reform was recognized in every country. During the transitional time various unsatisfactory experiments were made, some of the boldest experiments proving costly failures, yet serving, because of such features as were valuable, as a basis for further developments. Great Britain and France were almost the last countries touched by this movement, although in England throughout the 'nineties there was considerable improvement in actual scenic art and stage-mounting, as far as this could be brought about without the aid of improved stage mechanism.

Among those primarily responsible for this new epoch in scenic art in Great Britain were Sir Henry Irving and Mr Beerbohm Tree, both actor-managers, Mr Hubert von Herkomer, R.A., Sir L. Alma-Tadema, R.A., and Mr Edwin O. Sachs, architect. Although almost last in the application of stage reform in its best sense, England really completed the experimental period with the modernization of the Royal Opera House, Covent Garden, where, by the opening of the season of 1902, the directorate were provided with the latest improvements of mechanical skill for the almost complete re-equipment of stage scenery. This work of remodelling was carried out by the Grand Opera Syndicate, with Mr Edwin O. Sachs as technical adviser and architect. Modern mechanism has also been applied at the Apollo Theatre, London, where, however, the stage equipment was bodily imported from the Continent and does not include any mechanically or electrically driven parts, manual labour alone being used. The stage mechanism which was employed in the equipment of the Royal Opera House, Covent Garden, embodies the Sachs system of dividing the stage-floor into a few large sections and working them with the aid of electrical power, the Brandt system of counter-weighting for the suspension of all scenery from above, the application of light in four colours by electricity, and the designing of all scenery to accord as much as possible with nature, the whole mounting being built up on the basis of a flat stage as distinct from the sloping stage of old.

Stage Mechanism. The classification of stages generally, both home and foreign, whether for the production of opera or plays, should be made as follows: wood stages, wood and iron stages, and iron stages, with subdivisions according to the power chiefly employed in working the appliances. These subsections are: manual labour, hydraulics and electricity. Owing to the almost entire absence of steam for motor power in connexion with stage machinery, a separate subdivision for appliances where steam is employed is not required. With the wood stage and the wood and iron stage manual labour alone is utilized. But in the iron stage manual labour, hydraulic power and electric power are either used individually, or a combination of any two or three of these classes is applied. The first series of stages built in accordance with the principles of Stage Reform was erected on what was termed the "asphaleia" system, in which direct hydraulic power was utilized throughout. The stage-floor is divided into innumerable small sections supported on rams (some working telescopically), whilst everything suspended from above is also worked mechanically by hydraulic power. Notable examples are the Budapest Opera House and the Municipal Theatre at Halle.

The next type is that of the stage of the Court Theatre, Vienna, which, although based to a considerable extent on the "asphaleia" system, showed somewhat larger sections. These are suspended by cables and worked indirectly by small hydraulic rams placed at the side, whilst the whole of the top work is manipulated by manual labour with the partial assistance of counter-weights. The next type is the Brandt type, where the number of divisions of the stage is further reduced to a few medium-sized sections, worked by means of a combination of a central hydraulic ram and suspended cables duly counter-weighted. The top work in this case is entirely counter-weighted, and requires the least possible manual labour for manipulation. An example will be found at the Wiesbaden Court Theatre. We next have the Sachs system, where electric power is substituted for hydraulic power, the number of stage divisions limited to several large sections, suspended on cables partly counter-weighted and partly worked by electric motors, while the whole of the top work is balanced on a system similar to that of the Brandt, with intermediate electric motors for the manipulation of particularly heavy loads. It is this last system that has been adopted at the Covent Garden Opera House, with the modification that the top work is entirely operated on the latest development of the Brandt system of manual labour and counter-weights. Another example of the Sachs system, as far as individual stage sections are concerned, will be found in a portion of the Theatre Royal, Drury Lane.

Regarding the question of expense and practicability, the hydraulic system has generally been found to be expensive and impracticable. The system of the Court Theatre, Vienna, though practicable, is costly both in capital and annual outlay. The Brandt method of equipping the upper stage mechanism has been found particularly suitable for medium-sized theatres, and not expensive. The Sachs system has been found practicable, of moderate initial cost and minimum annual outlay. The advantages of electricity over hydraulic power have been most marked both in capital and in annual expense. There is of course a far greater initial outlay required to-day than with the wooden stage of old, but the saving in staff and wear and tear of the scenery, and the absence of expensive temporary makeshifts, repairs and reinstatements, compensate for this by a material reduction of annual charges. It is known as a fact that upon an overhaul of the Covent Garden equipment being ordered after five years' running, the contractors could not find anything to do in the way of repairs or reinstatements. The stage carpenter has long reigned supreme in England and France, although in England there are already one or two notable exceptions of men who are advancing to the position of engineers rather than carpenters. In Germany and Austria the stage carpenter is already being replaced in most theatres by men of engineering or technical training, as the more complex arrangements of a modern stage demand intelligent and careful control. It is merely a question of time for the engineer to obtain general control in these matters.

Scene-painting. Regarding the actual designing and painting of the scenery, the English scene-painter may now be considered in advance of his Continental and American colleagues, although the productions of some notable ateliers at Vienna and Munich run the English scene-painter's work very closely. In 1890 Vienna was in advance of England in scene-painting, but the English scene-painters have since then rapidly come to the front, and it is to be anticipated that it will never again be necessary to import scenery from Austria, as has been the case, both at the Theatre Royal, Drury Lane, and at the Royal Opera House, Covent Garden. As a matter of fact, scenery from Covent Garden and Drury Lane is already exported to the United States. The position of the scene-painter is particularly difficult, inasmuch as whilst artistic temperament and thorough knowledge of art are essential for the practice of his vocation, it is equally essential that he should be thoroughly practical and to a considerable extent a mechanic. He lacks recognition among artists and there is unfortunately a tendency to depreciate his work.

Modern Inventions. During the period of interregnum in stage reform there appeared a number of faddist inventions which, while creating public interest, cannot be considered of lasting practical utility. Thus in the United States an attempt was made to have a large platform constructed like a lift, bodily rising and falling, with three different tiers or stages on which scenery could be mounted at different levels and then raised or lowered into position. Again, at Munich, a scheme of turn-tables based on the Japanese revolving stage was put forward, but this can only be looked upon as an interesting experiment of little practical value.

Light. Numerous methods of illuminating the stage have similarly been attempted, with the aid of search-lights, and proscenium-lights, or by the absence of foot-lights, and the like, but the general method of lighting the stage from the top with battens, from the side with wing-ladders, and from below with foot-lights, if carefully regulated and skilfully handled, produces excellent results. The lighting arrangements as practised at the Royal Opera House, Covent Garden, in which building the lighting engineer is Mr Crawshaw and the consulting engineer for the lighting installation was Mr Bowles, leave nothing to be desired from an artist's point of view. The great difficulty of the light coming too strongly from below, *i.e.* from the foot-lights, can be overcome by the regulation and colouring of the lights.

As examples of modern mechanism, two photographs have been reproduced showing views of the electrical stage "bridges" of the Royal Opera House, Covent Garden, and of the Theatre Royal, Drury Lane, respectively, both on the Sachs system (see Pl. III.). A small general plan and section of the Covent Garden stage are also shown (see fig. 6), and another illustration (see Pl. IV.) presents the "gridiron" at Covent Garden on the Brandt system.

The following is a detailed description of the Covent Garden installation.

The stage may be described as consisting of a series of six horizontal sections running parallel with the curtain line from front to back, each section being 8 ft. wide, and the whole being followed by a large back or rear stage. The first section contains nothing but a plain "carpet cut," and openings to take the old-fashioned "grave" trap, "star" trap, or other similar contrivances. The second and third sections comprise large bridges, which can be raised 6 ft. above the stage or lowered 8 ft. below the stage, constructed in two levels, on the lower level of which appliances can be installed for the purpose of raising minor platforms above stage level or sinking traps and the like. The fourth, fifth and sixth sections comprise large bridges running right across the stage front, which can be raised 9 ft. above the stage or lowered 8 ft. below it. The back stage has no openings or mechanism beyond certain trap-doors to a scenery store, and the necessary electrical mechanism for raising and lowering scenery for storage purposes. Between the various sections of the stage, long longitudinal flaps, 2 ft. wide, have been formed, which can be easily opened to allow scenery to be passed through below for transformation scenes and the like. Each section is equipped with what is termed a pair of chariots, to hold "wing" lights placed on so-called wing ladders. All the electrical bridges are worked from the "mezzanine" level and from ordinary switchboards, and can be raised and lowered at various speeds, and take loads up to 2 tons. They can be moved without vibration or noise at a cost of about ½d. for power on a full rise when loaded.

Above the stage level each section has its series of lines to take cloths, borders, &c. Each section has a batten, from which the electric battens are suspended, and has also a large wooden lattice girder, from which heavy pieces of scenery can be hung. There are, on the average, about ten lines for ordinary battens, a girder batten, and a light batten to each section; besides these lines, there are the equipments of flying apparatus and the like, whilst in front there are, of course, the necessary lines for tableaux curtains, act-drops and draperies. Everything that is suspended from above can be worked at stage level or at either of the gallery levels, every scene being counter-weighted to a nicety, so that one man can easily handle it. No mechanical contrivance is required, and in practice quite a number of scenes can be rapidly changed in a very short time. Throughout the structure and mechanism steel has been used, with iron pulleys and wire cable; and the inflammable materials have been absolutely reduced to the flooring of the gridiron and galleries and the hardwood flooring of the stage and mezzanine. In other words, an absolute minimum of inflammable material replaces what was almost a maximum; and seeing that the electric light has been installed, the risk of an outbreak of fire or its spread has been materially reduced.

No mention of stage mechanism would be complete unless mention were made of the necessity of providing a carefully made and easily worked fire-resisting curtain of substantial but light construction. On the Continent metal curtains are favoured. In England the double asbestos curtain is more common. The London County Council prefer a steel framing with asbestos wire-wove cloth on both faces, the intervening space being filled with slag wool, well rammed and packed. Such curtains are somewhat

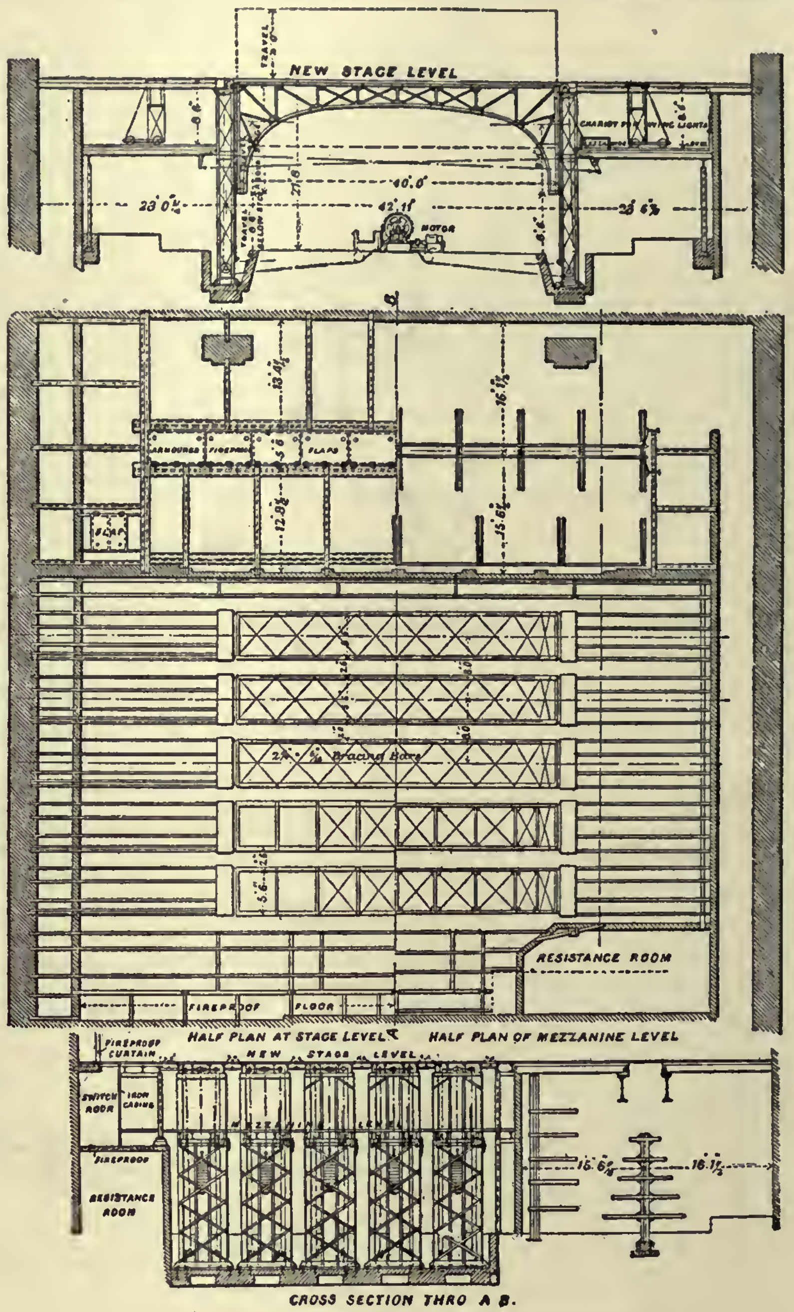

FIG. 6.—Plan and Section of Covent Garden Stage.

heavy and require counter-weighting to a nicety, but if well made and fitted may be deemed satisfactory. It is advisable to fit drenchers above fire-resisting curtains and to so arrange the working of the curtain that it can be lowered from four points, *i.e.* from both sides of the stage, from the prompt side flies and from the stage door. According to the Lord Chamberlain's rules, fire resisting curtains must be lowered once during a performance. This is a wise measure for testing the efficiency of the appliances.

"SPECTACLE"

The appeal to the eye has been the essential feature of dramatic production in its many stages of development from the earliest times of the miracle plays and "moralities," mummers and morris-dancers, down through the centuries, in the form of masques and ballets, to the luxuriance of scenic and costume display that is lavished on the latest forms of theatrical entertainment. Considering the enormous advance that has been made in mechanical appliances, more especially in the increased powers of illumination supplied by gas and electricity[1] as compared with oil and candles, we must acknowledge that the artistic achievement of spectacle has hardly kept pace with the times. If we may credit the veracity of contemporary chroniclers, the most elaborate effects and illusions were successfully attempted in the various courtly entertainments that are recorded under the Tudor and Stuart dynasties, and found perhaps their most sumptuous expression in the courts of Louis XIV. and Louis XV. It would be a difficult task for the most experienced of modern stage managers to rival the splendours of apparel and the ingenious devices that were exploited in increasing magnificence during successive periods, as described by Froissart, Holinshed, Cavendish, Stow, Pepys and other writers. The sums expended on these entertainments were prodigious, and a perusal of the extraordinarily detailed descriptions of such lavishly appointed masques as those designed by Inigo Jones in particular renders credible the statement that a certain masque presented before Charles I. at the Inns of Court in 1633 cost £21,000. Spectacle in its earlier phases appears to have existed chiefly in connexion with court and civic ceremonial: as evidenced in the wonderful pageantry of the Field of the Cloth of Gold; in such princely entertainment as the Revels at Kenilworth, when the Earl of Leicester welcomed Queen Elizabeth in a series of splendid fêtes; and in the more accomplished imaginings of Ben Jonson, decorated by Inigo Jones, such as the Inns of Court masque, already cited. The scenic effects and illusions which had evidently been brought to great perfection in these masques were not devoted to the service of the drama in the public theatres until Davenant introduced them at the period of the Restoration, although simple scenery, probably mere background "cloths," had been seen on the stage as early as 1605. The built-up stage pictures, familiar to us as "set-scenes," are said to owe their origin to Philip James de Loutherbourg, R.A., and to have been first used in 1777; but it is difficult to believe that some such elaborate constructions had not already enjoyed a term of popularity in view of the contemporary paintings and engravings of the epoch of Louis XIV., who was himself not averse from appearing (in 1653) as "Le Roi Soleil" in the midst of an *entourage* combining much that was artistic and fanciful with the most pompous and most absurd incongruities of character and costume. A greater measure of elegance and refinement distinguished the spectacles of the reign of Louis XV., inspired by the delicate art of Watteau, Boucher and Lancret, and preserved for our delectation in their delightful canvases. Under the French Revolution the spectacular ballet lost much of its prestige; and its decorative features were for a time principally associated with the fêtes inaugurated by the Republic, and presented in the classic costume, which the severity of the new régime adopted as a reaction, or as a protest against the frivolities and furbelows of the obliterated monarchy. The Festival of the Supreme Being, decreed by the National Convention, designed by David and conducted by Robespierre, was perhaps the most impressive spectacle of the close of the 18th century.

The 19th century saw spectacle devoted almost exclusively to theatrical entertainment. In London, melodrama, both of the romantic and domestic description, claimed its illustrative aid. At Drury Lane Theatre (which, with Covent Garden, the Adelphi and Astley's, was first illuminated by gas in 1817–18) the *Cataract of the Ganges*, with its cascade of real water and its prancing steeds, made a great sensation in 1823, and the same stage in 1842, under Macready's management, displayed the "moving wave" effect in the Sicilian views, painted by William Clarkson Stanfield for *Acis and Galatea*. The Lyceum Theatre from 1847 to 1855 introduced a long series of elegant extravaganzas from the pen of J. R. Planché, elaborately illustrated by the scenery of William Beverly. The *Golden Branch*, the *King of the Peacocks* and the *Island of Jewels* (Christmas 1849) were the most remarkable of these productions, and were noteworthy as originating the fantastic fairy pictures that became known as "transformation scenes," and were copied and popularized in all directions. Beverly's skilful brush was at a later date employed at Drury Lane to enhance the attractions of a succession of spectacular versions of Sir Walter Scott's novels, *Amy Robsart* (1870), *Rob Roy* (with a beautiful panorama of the Trossachs scenery), *Rebecca*, *England in the Days of Charles II.*, and others. Later still, under the régime of Sir Augustus Harris and his successors, spectacle at Drury Lane assumed even more costly proportions, and modern melodramas, representing well-known localities with extraordinary fidelity and all kinds of disasters from earthquakes to avalanches, have been alternated with sumptuously mounted pantomimes (so-called), in which the nominal fairy-tales were almost smothered by the paraphernalia of scenery and costume. It is remarkable that, for a "run" of ten weeks only, such a sum as £16,000 each can have been profitably expended on more than one of these productions.

London playgoers will recall the processional glories of *A Dream of Fair Women*, designed by Alfred Thompson; *The Land of Fairy Tales*, by Percy Anderson; and *The Silver Wedding* (Puss in Boots), *The Paradise of the Birds* (Babes in the Wood), and *The Gods and Goddesses of Olympus* (Jack and the Beanstalk), for which Mr Wilhelm was responsible. *The Armada*, a historical drama (1888), also deserves to be remembered for the completeness and excellence of its spectacular features. In addition to the names of Clarkson Stanfield and Beverly, already cited as masters of scenic art, it must not be forgotten that the skill of David Roberts was also devoted to the embellishment of the stage; and the names of Grieve, the Telbins (father and son), Hawes Craven, and J. Harker have in successive years carried on the best traditions of the art. Alfred Thompson was one of the first to revise the conventionalities of fanciful stage costume, and to impart a French lightness of touch and delicacy of colour. A ballet, *Yolande*, which he dressed for the Alhambra in the 'sixties, was the first Japanese spectacle to grace the English stage; and he was also mainly responsible for the attractions of *Babil and Bijou*, which cost upwards of £11,000 at Covent Garden Theatre in 1872, and was at the time considered to have surpassed all former spectacular accomplishments. It achieved, however, merely a *succès d'estime*, and has bequeathed to a later generation only the recollections of its "Spring" choir of boys, and of the brilliant danseuse, Henriette d'Or, who revived memories of the great days of the ballet, when Taglioni, Cerito, Elssler, Duvernay and other "Déesses de la Danse," appeared under Lumley's management at the old Her Majesty's Theatre in the Haymarket. Since the memorable tenancy of Sadler's Wells Theatre by Phelps (1844–62), Shakespeare and spectacle have been honourably associated. Charles Kean's revivals at the Princess's Theatre (1850–59) deservedly attracted considerable attention for the splendour and accuracy of their archaeology. Byron's *Sardanapalus* was also a triumph for the same management in 1853; and the same theatre three

[1] The Savoy Theatre, London, was first entirely lighted by electricity in 1882. The various methods of lighting used have been an important item in the production of striking effects. The old system of a row of "foot-lights," with their unpleasant upward shadow, is now almost obsolete. Dip candles were used till 1720, when moulded candles were introduced into French theatres. The next improvement was the lamp of M. Argand, with its circular wick. In 1822 gas was first used in a Parisian theatre, next came the oxyhydrogen lime-light, used for special effects, and then electric lighting.

The old way of producing lightning was to blow lycopodium or powdered resin with bellows through a flame, and this is still used in realistic effects of conflagrations. More effective lightning is now made by flashing the electric light behind a scene painted with clouds, in which a zigzag aperture has been cut out and filled with a transparent substance. Thunder is made by shaking large sheets of iron. Wind is imitated by a machine with a cogged cylinder, which revolves against coarse cloth tightly stretched. The sound of rain is produced by shaking parched peas in a metal cylinder.

decades later witnessed the production (December 1883) by Wilson Barrett of *Claudian*, a romantic poetic drama of classic days, mounted so exquisitely as to gain Ruskin's enthusiastic praise. But undoubtedly the earliest noteworthy alliance of spectacle with Shakespeare was made by Sir Henry Irving at the Lyceum. The art of Royal Academicians was happily enlisted to add lustre and distinction to his productions. *Ravenswood* and the sumptuously presented *Henry VIII.* (1892) owed much to the co-operation of Mr Seymour Lucas. Sir Lawrence Alma-Tadema supervised *Cymbeline* and *Coriolanus* (1901), whilst Sir Edward Burne-Jones inspired the decoration of *King Arthur* (1895). In Tennyson's *Cup* (produced in January 1881) and in the beautiful revival of *Romeo and Juliet* it was felt that perfection of stage illusion could scarcely go farther, but the next production, *Much Ado about Nothing*, with its superb church scene by Telbin, was admittedly Irving's crowning success, alike from the artistic, the dramatic, the spectacular and the financial standpoints. Great praise was equally won by the version of *Faust*, which was frankly spectacular, and by the more recent *Robespierre* by Sardou. Shakespeare and the poetic drama were also finely illustrated by Mr Beerbohm Tree, who secured Sir Lawrence Alma-Tadema's interest for *Hypatia* at the Haymarket, and *Julius Caesar* at the new His Majesty's; whilst for his later productions, *King John*, *A Midsummer Night's Dream*, *Herod* (by Stephen Phillips), *Twelfth Night* (1901), and such later plays as his revival of *Antony and Cleopatra* (1907), he was assisted by the designs of Percy Anderson, an artist who made his mark in the costumes for a series of the operas at the Savoy Theatre, notably the 15th-century dresses for the *Beauty Stone*.

Spectacular features of exceptional refinement distinguished the pantomime of *Cinderella*, presented by Mr Oscar Barrett at the Lyceum Theatre in Christmas 1893, and designed by Mr Wilhelm. This production also enjoyed a prosperous season in New York. The system of international exchange seems to hold good in stage spectacle as in other cases, and in return for English successes that have been welcomed in America, Augustin Daly's Shakespearean productions were greatly admired in London. Other entertainments of a more absolutely spectacular order found acceptance in London. In connexion with Barnum and Bailey's Hippodrome, Imré Kiralfy's show, *Nero*, constituted a "mammoth combination," and attracted crowds to "Olympia" in 1890. The success of this latter spectacle of colour and movement, which was also designed by Mr Wilhelm, induced Mr Kiralfy to produce a still more ambitious entertainment the following season, *Venice*, designed by the same artist. A spectacle on these lines may be regarded as the outcome of such ballets as have long been popular on the continent of Europe—especially in Italy, where grace of movement and spontaneity of gesture are natural to the people, and greatly facilitate such an enterprise as the famous *Excelsior* ballet of Manzotti, which lasted a whole evening, in several acts, and required the services of hundreds of figurantes. *Excelsior* was originally produced at La Scala, Milan, in January 1881, and was subsequently given with great success at the Eden Theatre, Paris, in 1883. The revived popularity of the modern ballet, as at the Empire Theatre, London, has also been associated with some memorable triumphs of spectacle with which the name of Mr Wilhelm was closely identified as designer. (C. Wi.)

Law Relating to Theatres.

It was not until comparatively late in Roman history that acting became a distinct calling. The troops of public actors (*ministeria publica*) were generally slaves, and their earnings enriched their masters more than themselves.

The regulation of the theatre by legislation (except as to structure) belongs chiefly to the time of the lower empire, in which it depended almost wholly upon constitutions of Theodosius and Valentinian, incorporated in the Theodosian Code (Tit. xv. 5, 6, 7), and a century later to a large extent adopted by Justinian. In the whole of this law there is an evident attempt at a compromise between the doctrines of Christianity and the old Roman love of public spectacles of all kinds. It deals less with theatrical representations proper than with gladiatorial contests and chariot races.[1] The Theodosian Code provided that the sacraments were not to be administered to actors save where death was imminent, and only on condition that the calling should be renounced in case of recovery. Daughters of actors were not to be forced to go on the stage, provided that they lived an honest life. An actress was to be allowed to quit the stage in order to become a nun. There were also numerous sumptuary regulations as to the dress of actors. None of the law which has been mentioned so far was adopted by Justinian, but what follows was incorporated in *Cod.* xi. 40 (*De Spectaculis et Scenicis*), which consists entirely of extracts from the Theodosian Code of a very miscellaneous nature. Provision was made for the exhibition of public games and theatrical spectacles by magistrates, practically confining them to exhibiting in their own cities. Statues of actors were not to be placed in the public streets, but only in the proscenium of a theatre. A governor of a province was entitled to take the money raised for public games for the purpose of repairing the city walls, provided that he gave security for afterwards celebrating the games as usual. Municipalities were encouraged to build theatres (*Dig.* 1, 10, 3). By *Novel* cxvii., it was ground for divorce if a wife went to the theatre without her husband's knowledge. In *Cod.* iii. 12, 11 (*De Feriis*) is a constitution of Leo and Anthemius forbidding dramatic representations on Sunday. The *Digest* (iii. 2) classed all who acted for hire (*omnes propter pecuniam in scenam prodeuntes*) as infamous persons, and as such debarred them from filling public offices. A mere contract to perform not fulfilled did not, however, carry infamy with it. By *Novel* li. actresses could retire from the stage without incurring a penalty even if they had given sureties or taken an oath. There was probably a censorship at certain periods,[2] as well as provisions for safety of the building and the audience (Tacitus, *Ann.*, iv. 63; Leonine Constitutions, cxiii.). The seats were allocated by the state, and the care of the building committed to certain magistrates (*Novel* cxlix. 2).

England.—In England, as in other countries of western Europe, theatrical legislation was of comparatively recent introduction. Such legislation was unnecessary as long as the theatre was under the control of the Church and actors under its protection, the Church having turned to its own uses what it was powerless to prevent. The earliest regulations were therefore, as might be expected, made by the Church rather than by the state. The ecclesiastical ordinances were directed chiefly against the desecration of churches, though they sometimes extended to forbidding attendance of the faithful as spectators at plays even of a harmless kind.[3] Sacraments and Christian burial were denied by the canon law to actors, whose gains, said St Thomas, were acquired *ex turpi causa*,[4] and who, if they exceeded what was proper, might be in mortal sin. It was a doubtful point as to whether spectators might not be in similar case. The same law forbade plays to be acted by the clergy, even under the plea of custom, as in Christmas week, and followed the code of Justinian in enjoining the clergy not to consort with actors or be present at plays (see *Decretals*, iii. 1, 12 and 15, *De Vitæ et Honestate Clericorum*). As late as 1603, canon lxxxviii. of the canons of the Church of England enacted that churchwardens were not to suffer plays in churches, chapels or churchyards. The latest occurrence of such a play seems to have been at Oxford in 1592.

The Reformation marks the period of transition from the ecclesiastical to the non-ecclesiastical authority over the drama. Precautions began to be taken by the crown and the legislature against the acting of unauthorized plays, by unauthorized persons, and in unauthorized places, and the acting of plays objectionable to the government on political or other grounds. The protection of the Church being withdrawn, persons not enrolled in a fixed company or in possession of a licence from the crown or justices were liable to severe penalties as vagrants. The history of the legislation on this subject is very curious. An act of the year 1572 enacted that "all fencers, bearwards, common players of interludes, and minstrels (not belonging to any baron of this realm, or to any other honourable person of greater degree)," wandering abroad without the licence of two justices at the least, were subject "to be grievously whipped and burned through the gristle of the right ear with a hot iron of the compass of an inch about." This statute was superseded by 39 Eliz. c. 4, under which the punishment of the strolling player is less severe, and there is no mention of justices. The jurisdiction of justices over the theatre disappears from legislation

[1] The word *ludi* seems sometimes to include, sometimes to exclude, dramatic performances. Its meaning in a particular instance depends on the context.

[2] If one may judge from Horace's line (*Sat.*, i. 10, 38): *Quae neque in aede sonent certantia judice Tarpa.*

[3] A large number of such ordinances will be found cited in Prynne, *Histriomastix;* Bossuet, *Maximes et réflexions sur la comédie;* Mariana, *De Spectaculis.* They followed the almost unanimous condemnation by the Christian fathers. See, for example, Chrysostom, *Contra Ludos et Theatra;* Tertullian, *De Spectaculis;* Augustine, *De Civ. Dei*, i. 31, *Confessions*, iii. 2; Dill, *Roman Society*, pp. 47, 117.

[4] For this reason it appears to have been the custom in France for actors to be married under the name of musicians. See *Hist. parlémentaire de la Révolution française*, vi. 381. The difficulties attending the funeral of Molière are well known.

from that time until 1788. In 39 Eliz. c. 4 there is a remarkable exception in favour of persons licensed by Dutton of Dutton in Cheshire, in accordance with his claim to liberty and jurisdiction in Cheshire and Chester, established in favour of his ancestor by proceedings in *quo warranto* in 1499.[1] The stricter wording of this act as to the licence seems to show that the licence had been abused, perhaps that in some cases privileges had been assumed without authority. In 14 Eliz. c. 5 the privileges of a player attached by service of a noble or licence from justices, in the later act only by service of a noble, and this was to be attested under his hand and arms. The spirit of the acts of Elizabeth frequently appears in later legislation, and the unauthorized player was a vagabond as late as the Vagrancy Act of 1744, which was law till 1824. He is not named in the Vagrancy Act of 1824. The Theatre Act of 1737 narrowed the definition of a player of interludes, for the purposes of punishment as a vagabond, to mean a person acting interludes,[2] &c., in a place where he had no legal settlement.

Before the Restoration there were privileged places as well as privileged persons, *e.g.* the court, the universities, and the inns of court. With the Restoration privilege became practically confined to the theatres in the possession of those companies (or their representatives) established by the letters patent of Charles II. in 1662. In spite of the patents other and unprivileged theatres gradually arose.[3] In 1735 Sir John Barnard introduced a bill "to restrain the number of playhouses for playing of interludes, and for the better regulation of common players." On Walpole's wishing to add a clause giving parliamentary sanction to the jurisdiction of the lord chamberlain, the mover withdrew the bill. In 1737 Walpole introduced a bill of his own for the same purpose, there being then six theatres in London. The immediate cause of the bill is said to have been the production of a political extravaganza of Fielding's, *The Golden Rump*. The bill passed, and the act of 10 Geo. II. c. 28 regulated the theatre for more than a century. Its effect was to make it impossible to establish any theatre except in the city of Westminster and in places where the king should in person reside, and during such residence only. The act did not confine the prerogative within the city of Westminster, but as a matter of policy it was not exercised in favour of the non-privileged theatres, except those where the "legitimate drama" was not performed. The legitimate drama was thus confined to Covent Garden, Drury Lane and the Haymarket from 1737 to 1843. In the provinces patent theatres were established at Bath by 8 Geo. III. c. 10, at Liverpool by 11 Geo. III. c. 16, and at Bristol by 18 Geo. III. c. 8, the act of 1737 being in each case repealed *pro tanto*. The acting of plays at the universities was forbidden by 10 Geo. II. c. 19. It is not a little remarkable that the universities, once possessing unusual dramatic privileges, should not only have lost those privileges, but have in addition become subject to special disabilities. The restrictions upon the drama were found very inconvenient in the large towns, especially in those which did not possess patent theatres. In one direction the difficulty was met by the lord chamberlain granting annual licences for performances of operas, pantomimes and other spectacles not regarded as legitimate drama. In another direction relief was given by the act of 1788 (28 Geo. III. c. 30), under which licences for occasional performances might be granted in general or quarter sessions for a period of not more than sixty days. The rights of patent theatres were preserved by the prohibition to grant such a licence to any theatre within eight miles of a patent theatre. During this period (1737–1843) there were several decisions of the courts which confirmed the operation of the act of 1737 as creating a monopoly. The exclusive rights of the patent theatres were also recognized in the Disorderly Houses Act, 1751, and in private acts dealing with Covent Garden and Drury Lane, and regulating the rights of parties, the application of charitable funds, &c. (see 16 Geo. III. cc. 13, 31; 50 Geo. III. c. ccxiv.; 52 Geo. III. c. xix.; 1 Geo. IV. c. lx.). The results of theatrical monopoly were beneficial neither to the public nor to the monopolists themselves. In 1832 a select committee of the House of Commons recommended the legal recognition of "stage-right" and the abolition of theatrical monopoly. The recommendations of the report as to stage-right were carried out immediately by Bulwer Lytton's Act, 3 & 4 Will. IV. c. 15 (see COPYRIGHT). But it was not till eleven years later that the Theatres Act, 1843, was passed, a previous bill on the same lines having been rejected by the House of Lords. The act of 1843 inaugurated a more liberal policy, and there is now complete "free trade" in theatres, subject to the conditions imposed by the act. The growth of theatres since that time has been enormous. Nor does the extension seem to have been attended with the social dangers anticipated by some of the witnesses before the committee of 1832.

The suppression of objectionable plays was the ground of many early statutes and proclamations. While the religious drama was dying out, the theatre was used as a vehicle for enforcing religious and political views not always as orthodox as those of a miracle play. Thus the act of 34 & 35 Hen. VIII. c. 1 made it criminal to play in an interlude contrary to the orthodox faith declared, or to be declared, by that monarch. Profanity in theatres seems to have been a crying evil of the time. Stephen Gosson attacked it as early as 1579 in his *School of Abuse*. The first business of the government of Edward VI. was to pass an act reciting that the most holy and blessed sacrament was named in plays by such vile and unseemly words as Christian ears did abhor to hear rehearsed, and inflicting fine and imprisonment upon any person advisedly contemning, despising or reviling the said most blessed sacrament (1 Edw. VI. c. 1). A proclamation of the same king in 1549 forbade the acting of interludes in English on account of their dealing with sacred subjects. In 1556 the council called attention to certain lewd persons in the livery of Sir F. Leke representing plays and interludes reflecting upon the queen and her consort and the formalities of the mass. The same queen forbade the recurrence of such a representation as the mask given by Sir Thomas Pope in honour of the Princess Elizabeth at Hatfield, for she "misliked these follies." By the Act of Uniformity, 1 Eliz. c. 2, it was made an offence punishable by a fine of a hundred marks to speak anything in the derogation, depraving or despising of the Book of Common Prayer in any interludes or plays. In 1605 "An Act to restrain the Abuses of Players" made it an offence punishable by a fine of £10 to jestingly or profanely speak or use certain sacred names in any stage play, interlude, show, may-game or pageant (3 Jac. I. c. 21). In consequence of the appearance of players in the characters of the king of Spain and Gondomar, an ordinance of James I. forbade the representation on the stage of any living Christian king. The first act of the reign of Charles I. forbade acting on Sunday. Puritan opposition to the theatre culminated in the ordinance of 1648, making it a crime even to be present as a spectator at a play.[4] After the Restoration there are few royal proclamations or ordinances, the necessary jurisdiction being exercised almost entirely by parliament and the lord chamberlain. Among the few post-Restoration royal proclamations is that of the 25th of February 1664–65, restraining any but the company of the Duke of York's theatre from entering at the attiring house of the theatre, and that of the 27th of February 1698–99 against immorality in plays.

Preventive censorship of the drama by an officer of state dates from the reign of Elizabeth. The master of the revels (see REVELS) appears to have been the dramatic censor from 1545 to

[1] The "advowry," as it was called, over the Cheshire minstrels lasted until 1756, when the latest minstrel court was held at Chester.

[2] Interludes were acted in the open air at Berriew in Montgomeryshire as lately as 1819, when the players were indicted before the Great Sessions of Wales. They had been prohibited in the Declaration of Sports (1633) and in the Propositions of Uxbridge (1644).

[3] See W. Nicholson, *The Struggle for a free Stage in London* (1907).

[4] For the anti-theatrical Puritan literature see Courthope, *History of English Poetry*, ii. 381.

1624, when he was superseded by his official superior, the lord chamberlain.[1] In some cases the supervision was put into commission. Thus with Tilney, the master of the revels in 1581, were associated by order of the privy council a divine and a statesman. In other cases it was delegated, as to Daniel the poet by warrant in 1603. The proposal to give statutory authority to the jurisdiction of the lord chamberlain led, as has been already stated, to the withdrawal of Sir John Barnard's bill in 1735, and to considerable debate before the bill of 1737 became law. Lord Chesterfield's objection to the bill in the House of Lords was not unreasonable. "If the players," said he, "are to be punished, let it be by the laws of their country, and not by the will of an irresponsible despot." A stage play must now be duly licensed before performance. § 12 of the act of 1843 prescribes that a copy of every new play and of every addition to an old play, and of every new prologue or epilogue or addition thereto (such copy to be signed by the master or manager), shall be sent to the lord chamberlain, and, if the lord chamberlain does not forbid it within seven days, it may be represented. § 13 empowers the lord chamberlain to fix a scale of fees for examination; the fee is now two guineas for a play of three or more acts, one guinea for a play of less than three acts. All plays represented previously to the act are held to be licensed. A play once licensed is licensed once for all unless the licence be revoked under § 14. The examination is the duty of a special officer of the lord chamberlain's department, the examiner of stage plays. In spite of occasional lapses of judgment, a belief in the wisdom generally shown in the exercise of the censorship has been confirmed by the report of the select committee of the House of Commons in 1866, and also by the report of the joint committee of both Houses in 1909. The censorship has been consistently supported in recent years by theatrical managers, but violently opposed by an advanced section of dramatic authors. There have been instances, no doubt, where perhaps both the lord chamberlain and his subordinate officer, the examiner of stage plays, have been somewhat nice in their objections. Thus, during the illness of George III., *King Lear* was inhibited. George Colman, when examiner, showed an extraordinary antipathy to such words as "heaven" or "angel." The lord chamberlain's powers are still occasionally exerted against scriptural dramas, less frequently for political reasons. Later instances are Oscar Wilde's *Salomé* (1892), *Joseph of Canaan* (1896), Maeterlinck's *Monna Vanna* (1902), Housman's *Bethlehem* (1902), Gilbert and Sullivan's *Mikado* (temporarily in 1907), and a play by Laurence Housman dealing with George IV. (1910). Before 1866 the lord chamberlain appears to have taken into consideration the wants of the neighbourhood before granting a licence, but since that year such a course has been abandoned. The joint committee in 1909 recommended that it should be optional for an author to submit a play for licence, and legal to perform an unlicensed play whether submitted or not, the risk of police intervention being taken. They also recommended that the reasons for which a licence should be refused should be: indecency, offensive personalities, the representation in an invidious manner of a living person or a person recently dead, violation of the sentiments of religious reverence, the presence of anything likely to conduce to crime or vice, or to cause a breach with a friendly power, or a breach of the peace.

A theatre may be defined with sufficient accuracy for the present purpose as a building in which a stage play is performed for hire. It will be seen from the following sketch of the law that there are a considerable number of different persons, corporate and unincorporate, with jurisdiction over theatres. A consolidation of the law and the placing of jurisdiction in the hands of a central authority for the United Kingdom would probably be convenient. The committee of 1866 recommended the transfer to the lord chamberlain of the regulation of all places of amusement, and an appeal from him to the home secretary in certain cases, as also the extension of his authority to preventive censorship in all public entertainments; but no legislation resulted. The committee of 1909 recommended the abolition of any distinction between theatres and music-halls. Several bills for the amendment of the law have been introduced, but without success in the face of more burning political questions.[2]

Building.—A theatre (at any rate to make it such a building as can be licensed) must be a permanent building, not a mere tent or booth, unless when licensed by justices at a lawful fair by § 23 of the act of 1843. It must, if in the metropolis, conform to the regulations as to structure contained in the Metropolis Management Act 1878, and the Local Government Act 1888. These acts make a certificate of structural fitness from the county council necessary as a condition precedent for licence in the case of all theatres of a superficial area of not less than 500 sq. ft. licensed after the passing of the act, give power to the council in certain cases to call upon proprietors of existing theatres to remedy structural defects, and enable it to make regulations for protection from fire. The existing regulations were issued on the 30th of July 1901 and 25th of March 1902. As to theatres in provincial towns, the Towns Improvement Act 1847, and the Public Health Act 1875, confer certain limited powers over the building on municipal corporations and urban sanitary authorities. In many towns, however, the structural qualifications of buildings used as theatres depend upon local acts and the by-laws made under the powers of such acts.

Performance.—To constitute a building where a performance takes place a theatre, the performance must be (*a*) of a stage-play, and (*b*) for hire. (*a*) By § 23 of the act of 1843 the word "stage-play" includes tragedy, comedy, farce, opera, burletta, interlude, melodrama, pantomime or other entertainment of the stage, or any part thereof. The two tests of a stage-play appear to be the excitement of emotion and the representation of action. The question whether a performance is a stage-play or not seems to be one of degree, and one rather of fact than of law. A *ballet d'action* would usually be a stage-play, but it would be otherwise with a *ballet divertissement*. § 14 empowers the lord chamberlain to forbid the acting of any stage-play in Great Britain whenever he may be of opinion that it is fitting for the preservation of good manners, decorum, or the public peace to do so. § 15 imposes a penalty of £50 on any one acting or presenting a play or part of a play after such inhibition, and avoids the licence of the theatre where it appears. Regulations of police respecting the performance are contained in 2 & 3 Vict. c. 47, and in many local acts. A performance may also be proceeded against as a nuisance at common law, if, for instance, it be *contra bonos mores* or draw together a great concourse of vehicles, or if so much noise be heard in the neighbourhood as to interfere with the ordinary occupations of life. Very curious instances of proceedings at common law are recorded. In Sir Anthony Ashley's case (2 Rolle's Rep. 109), 1615, players were indicted for riot and unlawful assembly. In 1700 the grand jury of Middlesex presented the two play-houses and also the bear-garden on Bankside (the "Paris garden" of *Henry VIII.* act v. sc. 3) as riotous and disorderly nuisances. Performances on Sunday, Good Friday, and Christmas day are illegal. Regulations as to the sale of intoxicating liquors during the performance are made by the licensing acts and other public general acts, as well as by local acts and rules made by county councils. It is frequently a condition of the licence granted to provincial theatres that no excisable liquors shall be sold or consumed on the premises. The excise duty where such liquors are sold varies according to the annual value of the theatre up to a maximum of £20. The Dangerous Performances Acts, 1879 and 1897, forbid under a penalty of £10 any public exhibition or performance whereby the life or limbs of a child under the age of sixteen if a boy, eighteen if a girl, shall be endangered. It also makes the employer of any such child indictable for assault where an accident causing actual bodily harm has happened to the child, and enables the court on conviction of the employer to order him to pay the child compensation not exceeding £20. The Prevention of Cruelty to Children Act 1904 forbids a child to appear in any public entertainment without a licence from a petty sessional court. (*b*) The performance must be for hire. § 16 of the act of 1843 makes a building one in which acting for hire takes place, not only where money is taken directly or indirectly, but also where the purchase of any article is a condition of admission, and where a play is performed in a place in which excisable liquor is sold. In the case of *Shelley* v. *Bethell*, 1883 (Law Reports, 12 Q.B.D. 11), it was held that the proprietor of a private theatre was liable to penalties under the act, though he lent the theatre gratuitously, because tickets of admission were sold in aid of a charity.

Licensing of Building.—By § 2 of the act of 1843 all theatres (other than patent theatres) must be licensed. By § 7 no licence

[1] It was probably through his influence that the expletives in Shakespeare were edited. The quarto of 1622 contains more than the folio of 1623.

[2] Dryden's words in the "Essay on Satire" (addressed to the earl of Dorset, lord chamberlain) still describe the duties of the office. "As lord chamberlain I know you are absolute by your office in all that belongs to the decency and good manners of the stage. You can banish from thence scurrility and profaneness, and restrain the licentious insolence of poets and their actors in all things that shock the public quiet or the reputation of private persons under the notion of humour."

is to be granted except to the actual and responsible manager, who is to be bound by himself and two sureties for due observance of rules and for securing payment of any penalties incurred. The metropolitan theatres other than the patent theatres (as far at least as they are included in the boroughs named in the act of 1843) are licensed by the lord chamberlain. By § 4 his fee on grant of a licence is not to exceed 10s. for each month for which the theatre is licensed. The lord chamberlain appears to have no power to make suitable rules for enforcing order and decency. He can, however, by § 8, suspend or revoke a licence or close a patent theatre where any riot or misbehaviour has taken place. He has issued a code of regulations.

Provincial theatres fall under three different licensing authorities. The lord chamberlain licenses theatres in Windsor and Brighton, and theatres situated in the places where the king occasionally resides, but only during the time of such occasional residence (§ 3). Theatres at Oxford and Cambridge, or within 14 m. thereof, are licensed by the justices having jurisdiction therein, but before any such licence can come into force the consent of the chancellor or vice-chancellor must be given. The rules made by the justices for the management of the theatre are subject to the approval of the chancellor or vice-chancellor, who may also impose such conditions upon the licence as he thinks fit. In case of any breach of the rules or conditions, he may annul the licence (§ 10). All other provincial theatres are licensed by the county councils or county borough councils[1] under s. 7 of the act of 1888, except in case of a special and temporary performance, where justices still grant the licence as they did in all cases before that act came into operation. The regulations of the London County Council are dated the 27th of July 1897. Penalties are imposed by the act for keeping or acting in an unlicensed theatre, and for producing or acting in an unlicensed play. A contract to perform in an unlicensed theatre is unenforceable.

Music Halls.—Music was at no time the object of restrictions as severe as those imposed upon the drama. The present English act governing music halls, the Disorderly Houses Act 1751, was passed probably in consequence of the publication in 1750 of Fielding's *Inquiry into the Causes of the late Increase of Robbers.* It is remarkable that two works of the same writer should from opposite causes have led to both theatre and music-hall legislation of lasting importance. The act was originally passed for a term of three years, but was made perpetual by 28 Geo. II. c. 19. It applies only to music halls within 20 m. of London and Westminster. Every such music hall must be licensed at the Michaelmas quarter sessions, the licence to be signified under the hands and seals of four or more justices. The licence may be granted for music or dancing or both. Public notice of the licence is to be given by affixing over the door the inscription "Licensed in pursuance of act of parliament for," with the addition of words showing the purpose. The penalty for keeping an unlicensed music hall is £100. This act is amended as to Middlesex by the Music and Dancing Licences (Middlesex) Act 1894, putting the licensing into the hands of the county council. Regulations were made by the council under this act on the 31st of July 1900 and the 27th of June 1901. Music halls beyond the radius of 20 m. from London and Westminster are mainly governed by the Public Health Act 1890, the licensing authority being the licensing justices. There is no censorship of music-hall performance, the only remedy for anything objectionable is for the licensing authority to withdraw the licence or refuse to renew it.

See generally W. N. M. Geary, *Law of Theatres and Music Halls* (1885); C. Hamlyn, *Manual of Theatrical Law* (1891); A. A. Strong, *Dramatic and Musical Law* (1898); J. B. Williamson, *Law of Licensing* (1902).

Scotland.—In Scotland the theatre has always exercised a smaller amount of influence than in England, and there has been little exclusively Scottish legislation on the subject. 1555, c. 40, discountenanced certain amusements of a semi-theatrical kind by enacting that no one was to be chosen Robert Hude (*sic*), Little John, abbot of unreason, or queen of May. A proclamation of James VI. in 1574, and 1579, c. 12, followed the lines of English legislation by making persons using unlawful plays, such as jugglery or fast and loose, punishable as vagabonds. In 1574 the General Assembly claimed to license plays, and forbade representations on Sunday. As in England, the licensing power seems then to have passed from the church to the crown, for in 1599 James VI. licensed a theatre at Edinburgh. 1672, c. 21, exempted comedians while upon the stage from the sumptuary provisions of the act respecting apparel. The chamberlain of Scotland, while such an office existed, appears to have exercised a certain police jurisdiction over theatres. The Theatres Act 1843 extends to Scotland, as did also the previous act of 1737, and further provisions are made by the Burgh Police Act 1892.

Ireland.—Theatrical legislation, as far as it went, was based upon English models. Thus ridicule of the liturgy was forbidden by 2 Eliz. c. 2 (Ir.); common players of interludes and wandering minstrels were deemed vagabonds, 10 & 11 Car. I. c. 4 (Ir.). In 1786 an act was passed to enable the crown to grant letters patent for one or more theatres in Dublin city and county, 26 Geo. III. c. 57 (Ir.). The preamble alleges that the establishing of a well-regulated theatre at the seat of government will be productive of public advantage and tend to improve the morals of the people. Exceptions from the restrictions of the act were made in favour of entertainments for the benefit of the Dublin lying-in hospital and exhibitions of horsemanship or puppet-shows. The existing theatre and music-hall acts do not apply to Ireland, except the Public Health Act 1890, s. 51.

British Colonies.—There is a large amount of legislation. An example is the Victoria Act, No 1430 (1897), giving the chief secretary power to cancel or suspend the licence of any theatre if used on Sunday without special permit.

United States.—Public entertainments, dramatic or other, are usually under the control of the municipal authorities, and there is no act of Congress on the subject, except one of 1898 imposing a temporary war tax on the theatres. In most states there is state legislation, requiring places of public entertainment to be licensed by the proper authority. In many states it is a condition of the licence that intoxicating liquors shall not be sold in such places. Other conditions, more or less usual, are that there shall be no Sunday or dangerous performances, that acrobats shall be properly protected, and that female waiters shall not be employed. Structural qualifications are in some cases made necessary. Thus in 1885 the New York legislature passed an act containing many minute provisions for ensuring the safety of theatres against fire. A characteristic piece of legislation is the New York Act of 1873, c. 186, enacting that no citizen is to be excluded from a theatre by reason of race, colour or previous condition of servitude. This act of course merely carries out the important principle affirmed in art. xiv. of the amendments to the constitution of the United States. There are two curious and conflicting decisions of other states on the matter. Missouri held that a manager could discriminate against a person of colour, Michigan that he could not (see Green's *Digest*, vol. i. 642).

Continental Europe.—The principal points in which the continental theatre differs from the English are that Sunday is the most important day, and that the theatre is often owned or subsidized by the state or a municipality. In France there has been much legislation since the days of the Revolution, the principal law being one of 1864. A feature is the tax known as *le droit des pauvres*, which has been the subject of much discussion. The *censure préalable* was abolished in 1906. The object is attained by police penalties. Most of the authorities will be found in Dalloz, Supplement, vol. xvii., and, for the older law, Lacan, *La Législation et la jurisprudence des théâtres* (1853), and Maugras, *Les Comédiens hors de la loi* (1887), may be consulted. Italy has produced at least two modern works on the subject, Rivalta, *Storia e Sistema del Diritto dei Teatri* (1886), and Tabanelli, *Codice del Teatro* (1901). What strikes one is how little special legislation there is on the subject. The penal code meets most cases. Spain retained the *autos sacramentales* much longer than other countries retained the religious drama. Legislation begins very early. The *Siete Partidas* enacts that the clergy are not to take part as actors or spectators in scurrilous plays (*juegos por escarnio*). Cervantes in the first part of *Don Quixote* makes the canon of Toledo regret that the government had not appointed a censor to prevent the acting of plays not only injurious to morals but also offending against the classical rules of the drama. There is a considerable amount of law in the Ottoman empire; details will be found in G. Young, *Corps de droit ottoman*, vol. ii. 320 (1904). (J. W.)

THEBES (Θῆβαι), the Greek name of the ancient capital of Upper Egypt, presumably an Egyptian name (*e.g.* Zēmi, seen in -σημις, -τημις) assimilated to that of the Greek city. It occurs in Homer (*Il.* ix. 381–4) where it has the epithet ἑκατόμπυλος, "hundred-gated," probably derived in the first place from the gateways of its endless temples, though perhaps misunderstood as if it referred to a city with a hundred gates in the circuit of its walls. Thebes was never a walled city in this sense, though its vast temple enclosures in different quarters would form as many fortresses in case of siege or tumult. Its Egyptian name was Wesi (or Wis?), later Ne, "the city" (sometimes Ne-Amun, hence No-Amon in Nahum iii. 8), and different quarters were known by special names. In non-literary Greek Thebes was regularly called Diospolis the Great. Ammon, Amen-Rē, or Amenrasonther ("Ammon-Rē king of the gods") was its deity, with his consort Mut and their child Khons. Mont also was a local deity and Hathor presided over the western cliffs of Thebes. In very ancient times the city lay on the east bank, the necropolis on the west. As it grew, however, although the necropolis was still confined to the west bank, a vast city of temples, priests and necropolis people, to which

[1] The councils may delegate their authority to justices, a district council, or a committee of their own body, such as the Theatre and Music Hall Committee of the London County Council.

were added royal palaces and their accompaniments, covered the western shore as far back as the desert hills. The chief nucleus of the ancient Wēsi was a town about the temple of Karnak: it probably reaches back to the prehistoric period. At Drah abu'l nagga, opposite to it, are tombs of its princes under the VIth Dynasty. The temple of Karnak is no doubt of immemorial antiquity. Perhaps no sculpture earlier than the XIIth Dynasty has survived there, but Senwosri I. dedicated statues to his predecessors of the Vth Dynasty who had probably showed their devotion to Ammon in a substantial manner, and Cheops of the IVth Dynasty is named in it. After the end of the Old Kingdom Thebes grew from an obscure provincial town to be the seat of a strong line of princes who contended for supremacy with Heracleopolis and eventually triumphed in the XIth Dynasty of Manetho. The most important monument of the Middle Kingdom now extant at Thebes is the funerary temple of Menthotp III. of this dynasty, which has been revealed by the excavations of the Egypt Exploration Fund at Deir el Bahri (see ARCHITECTURE, section *Egyptian*, fig. 4): and the period is well represented by an abundance of statues of the XIIth and XIIIth dynasties from the temple of Karnak. The name Amenemhe, so common in the XIIth Dynasty, shows the importance of the Theban god at this time. It was not, however, till the XVIIIth Dynasty, the beginning of the New Empire, that the whole site began to be occupied by monuments which have survived to the present day. The early rulers of this dynasty down to Tethmosis III. developed Karnak, and on the west bank built the great funerary temple of Deir el Bahri and smaller temples as far south as Medinet Habu, and began the long series of royal tombs in the famous Valley of the Tombs of the Kings far back in the desert behind Deir el Bahri. Amenophis III. continuing, transformed western Thebes monumentally: built three great temples in addition, that of Mont on the north of Karnak, the temple of Mut on the south and the temple of Ammon at Luxor, and connected the last two with the state temple of Karnak by avenues of sphinxes. On the west bank of the huge colossi of Memnon marked the entrance of his funerary temple, a magnificent building which was afterwards destroyed, and the great lake of Birket Habu was dug and embanked in front of his brick palace at the extreme south. The chief energies of this king in fact were expended on developing the south extremity of Thebes on both banks. The city and its monuments now covered an area about three miles square. After this Thebes experienced a serious set-back with the heresy of Akhenaton, the son of Amenophis III. He moved his capital northward to Akhetaton (El Amarna) and strove to suppress the worship of Ammon, doing infinite damage to the monuments of Thebes by defacing his name and figure. After about twenty years, however, the reaction came, Thebes was again the capital, and a little later under Seti (Sethos) I. and Rameses II. of the XXth Dynasty it was raised to greater architectural magnificence than ever. These two kings built the great columnar hall of Karnak, added a large court with pylons to Luxor, and on the west bank built the funerary temple of Seti at Kurna, and the Ramesseum with its gigantic colossus, besides other edifices of which only traces remain. Under the XVIIIth and XIXth Dynasties Thebes was at the height of its greatness. Conquering Pharaohs brought home trains of prisoners and spoil, embassies came thither of strange people in every variety of costume and of every hue of skin, from Ethiopia, Puoni (Punt), Mesopotamia, Asia Minor, Libya, and the islands of the Mediterranean, bringing precious stones, rare animals, beautiful slaves, costly garments and vessels of gold and silver, while the ground shook with the movement of colossal architraves, statues and obelisks. The tombs of the XVIIIth Dynasty on the west bank and the sculptures in the temples reflect the brilliancy of these days, but even the reign of Rameses II. marks the beginning of the decline of Thebes. The enormous constructive energy of the proud Pharaoh, instead of being concentrated on the capital, was expended with almost equal lavishness on other parts of the country. In every city he left his mark. A great temple at Tanis boasted a larger colossus than existed in Thebes: Heliopolis and Memphis must have been lavishly adorned, and the temples of Abu Simbel (*q.v.*) alone would have been sufficient to satisfy the ambition of many of the great Pharaohs. After Rameses II. the efforts of all his successors combined could add little to the wonders of Thebes. The temple and tower of Rameses III. (XXth Dynasty) at Medinet Habu, his tomb in the Biban el Moluk, the temple of Khons (Rameses III. and later) and the court of Sheshonk I. (XXIInd Dynasty) at Karnak are the only great achievements.

For the rest there are the tombs of many kings in the Biban el Moluk and a good deal of comparatively petty construction and tinkering, with the help of stone robbed from older structures. Earlier and greater kings had remorselessly destroyed buildings which interfered with their own plans. The "Memnon" temple of Amenophis III. had already gone, sacrificed perhaps to Akhenaton's god. Rameses II. had plundered his predecessors' monuments for materials. Hitherto Thebes had been glorified by the process, but henceforth it was rather to perish. The tide of prosperity was flowing northward and such monumental energy as remained was expended more widely. For several centuries after the fall of the New Empire Thebes was but one of several alternating or contemporaneous capitals. Memphis, Tanis, Bubastis, Sais, Heracleopolis had at one time or another at least equal claims. The Ethiopian conquerors of Egypt made Thebes their Egyptian capital, but in 668 Assur-bani-pal sacked the city. Psammetichus did not neglect it, and during the XXVIth Dynasty Petemenopi, a wealthy priest and official, excavated for himself the greatest private tomb that ever was made. Probably every king that included Thebes in his realm, except the Assyrians and the Persians, left his memorial there in chapels erected or sculptures added. Of the Persians, however, not even Darius is traceable at Thebes; on the other hand, there is no support for the tradition that Cambyses destroyed its monuments. Ptolemy I. gave a new capital to the upper country in the Greek foundation of Ptolemais, and thus struck a fresh blow at the prosperity of Thebes. For a short period in the reign of Epiphanes, when Upper Egypt was in rebellion against the Ptolemaic rule, Thebes was the capital of independent native dynasts. In a later rebellion, Thebes was captured after a three years' siege and severely punished by Lathyrus (Ptolemy X., Soter II.). In the reign of Augustus, having joined in the insurrection against the tax-gatherers, it was destroyed by Cornelius Gallus and became a collection of villages. Though its vast buildings have since served as quarries for mill-stones and for the lime-burner, Thebes still offers the greatest assemblage of monumental ruins in the world.

We will now briefly enumerate the principal groups of monuments. On the east bank at Karnak stand the great state temple of Amen-Rē with its obelisks of Hatshepsut and Tethmosis I. and the vast columnar hall of Rameses II.; the temple of Mūt and the well-preserved temple of Khons; the temple of Luxor and avenues of rams and sphinxes connecting all these. These temples are described in the articles KARNAK, LUXOR and ARCHITECTURE: *Egyptian*. On the west bank, in front of the necropolis, on the edge of the desert or projecting into the cultivation, was a low row of temples: the northernmost, placed far in front of the others, is the well-preserved temple of Seti I. at Kurna; then follow the Ramesseum and Medinet Habu; and the foundations of many others can be traced. The temple of Amenophis III., to which the colossi of "Memnon" were attached, was again far forward of the line. The Ramesseum contains the remains of a stupendous seated colossus, in black granite, of its builder Rameses II., thrown on its face. When perfect it was probably 57 ft. high and weighed about 1000 tons, surpassing the "Memnon" statues of Amenophis III. in size and weight. The temple of Rameses III. at Medinet Habu, sculptured with very interesting scenes from his Syrian, Libyan and other wars and from religious festivals, is remarkable also for the unique entrance-tower which probably formed part of the royal palace. Northward and far back in the foot-hills is the Ptolemaic temple of Deir el Medina, and beyond under the cliffs of Deir el Bahri the terrace temple of Queen Hatshepsut, the walls of which are adorned with scenes from her expedition to Puoni (Somaliland) in search of incense trees, and many other subjects. The necropolis extends from Kurna in the north through Drah abu'l nagga, the Assasif, and Shekh abd el Kurna to Kurnet Murrai of Medinet Habu. The finest tombs are of the XVIIIth Dynasty. Far behind Medinet Habu are the Tombs of the Queens, where royal relatives of the XXth Dynasty are buried; and immediately behind the lofty cliffs of Deir el Bahri, but accessible only by a very circuitous route from Kurna, are the tombs of the kings (from Tethmosis I. onward to the end of the XXth Dynasty) in the Biban el Moluk and the Western Valley. They are decorated with religious scenes and texts, especially those which describe the passage of the sun through the underworld. Those of Seti I. and Rameses III. are the most remarkable. These royal sepulchres are long galleries excavated in the rock with chambers at intervals: in one of the innermost chambers was laid the body in its sarcophagus. In the XXIst Dynasty, when tomb robberies were rife and most of their valuables had been stolen, the royal mummies were removed from place to place and at last deposited for safety in the tomb of Amenophis II. and in the burial-place of the priest-kings at Deir el Bahri. The finding of the two *cachettes* nearly intact has been among the greatest marvels of archaeological discovery, and the systematic exploration of the Valley of the Tombs of the Kings by Theodore M. Davis has been annually rewarded with results of the highest interest.

Petrie, *Six Temples at Thebes* (ruined temples on west bank), (London, 1897); G. Daressy, *Notice explicative des ruines de Médinet Habu* (Cairo, 1897); G. Maspero, " Les Momies royales de Deir el Bahari " in *Mémoires de la mission archéologique française au Caire*, tome I.; and many other works. (F. Ll. G.)

THEBES (anciently Θῆβαι, *Thebae*, or in poetry sometimes Θήβα, in modern Greek *Phiva*, or, according to the corrected pronunciation, *Thivae*), an ancient Greek city in Boeotia, is situated on low hilly ground of gentle slope a little north of the range of Cithaeron, which divides Boeotia from Attica, and on the edge of the Boeotian plain, about 44 m. from Athens, whence it is reached by two carriage-roads and by railway since 1904. It has about 4800 inhabitants, and is the seat of a bishop. The present town occupies the site of the ancient citadel, the Cadmea; two fragments of ancient wall are visible on the north, and another, belonging either to the citadel or the outer wall, on the south. Two streams, rising a little south of the town, and separated by an average distance of about half a mile, flow on the two sides, and are lost in the plain. These are the ancient Ismenus on the east and Dirce (Δίρκη) on the west, which gave to the town its name διπόταμος. The Dirce, now Plakiótissa, has several springs. From the west side of the Cadmea another copious fountain (Paraporti) falls to the Dirce. In a suburb to the east is another (Fountain of St Theodore), and north-west are two more. The Cadmea itself is supplied with water brought from an unknown source to the south by works supposed of prehistoric antiquity. It now enters the town by an aqueduct of twenty arches of Frankish construction. The " waters " of Thebes are celebrated both by Pindar and by the Athenian poets, and the site is still, as described by Dicaearchus (3rd century B.C.), " all springs," κάθυδρος πᾶσα. One, from which a pasha of Negroponte (Euboea) is said to have supplied his table, is still called " the spring of the cadi." Some of the marble basins, seats, &c., remain, and, with the fragments of wall above mentioned, are the only relics of the classic time. The most curious of later buildings is the church of St Luke, south-east of the Cadmea, believed to contain the tomb of the evangelist. From the abundance of water the place is favourable to gardens, and the neighbouring plain is extremely fertile. But the population is scanty, and the town at present of no importance.

History.—The record of the earliest days of Thebes was preserved among the Greeks in an abundant mass of legends which rival the myths of Troy in their wide ramification and the influence which they exerted upon the literature of the classical age. Five main cycles of story may be distinguished: (1) the foundation of the citadel Cadmea by Cadmus, and the growth of the Sparti or " Sown Men " (probably an aetiological myth designed to explain the origin of the Theban nobility which bore that name in historical times); (2) the building of a " seven-gated " wall by Amphion, and the cognate stories of Zethus, Antiope and Dirce; (3) the tale of the " house of Laius, " culminating in the adventures of Oedipus and the wars of the " Seven " and the Epigoni; (4) the advent of Dionysus; and (5) the exploits of Heracles. It is difficult to extract any historical fact out of this maze of myths; the various groups cannot be fully co-ordinated, and a further perplexing feature is the neglect of Thebes in the Homeric poems. At most it seems safe to infer that it was one of the first Greek communities to be drawn together within a fortified city, that it owed its importance in prehistoric as in later days to its military strength, and that its original " Cadmean " population was distinct from other inhabitants of Boeotia such as the Minyae of Orchomenus.

In the period of great invasions from the north Thebes received settlers of that stock which in historical times was homogeneously spread over Boeotia. The central position and military security of the city naturally tended to raise it to a commanding position among the Boeotians, and from early days its inhabitants endeavoured to establish a complete supremacy over their kinsmen in the outlying towns. This centralizing policy is as much the cardinal fact of Theban history as the counteracting effort of the smaller towns to resist absorption forms the main chapter of the story of Boeotia. No details of the earlier history of Thebes have been preserved, except that it was governed by a land-holding aristocracy who safeguarded their integrity by rigid statutes about the ownership of property and its transmission. In the late 6th century the Thebans were brought for the first time into hostile contact with the Athenians, who helped the small fortress of Plataea to maintain its independence against them, and in 506 repelled an inroad into Attica. The aversion to Athens best serves to explain the unpatriotic attitude which Thebes displayed during the great Persian invasion. Though a contingent of 700 was sent to Thermopylae and remained there with Leonidas to the end, the governing aristocracy soon after joined the enemy with great readiness and fought zealously on his behalf at the battle of Plataea (479). The victorious Greeks subsequently punished Thebes by depriving it of the presidency of the Boeotian League, and an attempt by the Spartans to expel it from the Delphic amphictyony was only frustrated by the intercession of Athens. In 457 Sparta, needing a counterpoise against Athens in central Greece, reversed her policy and reinstated Thebes as the dominant power in Boeotia. The great fortress served this purpose well by holding out as a base of resistance when the Athenians overran and occupied the rest of the country (457–447). In the Peloponnesian War the Thebans, embittered by the support which Athens gave to the smaller Boeotian towns, and especially to Plataea, which they vainly attempted to reduce in 431, were firm allies of Sparta, which in turn helped them to besiege Plataea and allowed them to destroy the town after capture (427). In 424 at the head of the Boeotian levy they inflicted a severe defeat upon an invading force of Athenians at Delium, and for the first time displayed the effects of that firm military organization which eventually raised them to predominant power in Greece. After the downfall of Athens at the end of the Peloponnesian War the Thebans, finding that Sparta intended to protect the states which they desired to annex, broke off the alliance. In 404 they had urged the complete destruction of Athens, in 403 they secretly supported the restoration of its democracy in order to find in it a counterpoise against Sparta. A few years later, influenced perhaps in part by Persian gold, they forced on the so-called Corinthian War and formed the nucleus of the league against Sparta. At the battles of Haliartus (395) and Coroneia (394) they again proved their rising military capacity by standing their ground against the Spartans. The result of the war was especially disastrous to Thebes, as the general settlement of 387 stipulated the complete autonomy of all Greek towns and so withdrew the other Boeotians from its political control. Its power was further curtailed in 382, when a Spartan force occupied the citadel by a treacherous *coup-de-main*. Three years later the Spartan garrison was expelled, and a democratic constitution definitely set up in place of the traditional oligarchy. In the consequent wars with Sparta the Theban army, trained and led by Epaminondas and Pelopidas (*q.v.*), proved itself the best in Greece. Some years of desultory fighting, in which Thebes established its control over all Boeotia, culminated in 371 in a remarkable victory over the pick of the Spartans at Leuctra (*q.v.*). The winners were hailed throughout Greece as champions of the oppressed. They carried their arms into Peloponnesus and at the head of a large coalition permanently crippled the power of Sparta. Similar expeditions were sent to Thessaly and Macedonia to regulate the affairs of those countries. But the predominance of Thebes was short-lived. The states which she protected were indisposed to commit themselves permanently to her tutelage, and the renewed rivalry of Athens, which had been linked with Thebes since 395 in a common fear of Sparta, but since 371 had endeavoured to maintain the balance of power against her ally, prevented the formation of a Theban empire. With the death of Epaminondas in 362 the city sank again to the position of a secondary power. In a war with the neighbouring state of Phocis (356–346) it could not even maintain its predominance in central Greece, and by inviting Philip II. of Macedon to crush the Phocians it extended that monarch's power within dangerous proximity to its frontiers. A revulsion of feeling was completed in 338 by the orator Demosthenes, who persuaded Thebes to join Athens in a final attempt to bar Philip's advance upon Attica. The Theban contingent fought bravely on behalf of Grecian liberty in the decisive battle of Chaeroneia, and bore the brunt of the slaughter. Philip was content to deprive Thebes of her dominion over Boeotia; but an unsuccessful revolt in 335 against his son Alexander was punished by the complete destruction of the city, except, according to tradition, the house of the poet Pindar. Though restored in 315 by Cassander, Thebes never again played a prominent part in history. It suffered from the establishment of Chalcis as the chief fortress of central Greece, and was severely handled by the Roman conquerors Mummius and Sulla. Strabo describes it as a mere village, and in Pausanias's time (A.D. 170) its citadel alone was inhabited. During the Byzantine period it served as a place of refuge against foreign invaders, and from the 10th century became a centre of the new silk trade. Though severely plundered by the Normans in 1146 it recovered its prosperity and was selected by the Frankish dynasty de la Roche as its capital. In 1311 it was destroyed by the Catalans and passed out of history.

The most famous monument of ancient Thebes was the outer wall with its seven gates, which even as late as the 6th century B.C. was probably the largest of artificial Greek fortresses. The names of the gates vary, but four are constant—the Proetides, Electrae, Neistae or Neitae, and Homoloides; Pausanias gives the others as Ogygiae, Hypsistae, Crenaeae. There is evidence that the gate Electrae was on the south, and near it was the tomb of the Thebans who fell at the capture by Alexander. The gates shown to Pausanias as Neistae and Proetides led respectively north-west and north-east. Two of the springs have been identified with some probability—that of St Theodore with the Oedipodea, in which Oedipus is said to have purged himself from the pollution of homicide, and the Paraporti with the dragon-guarded fountain of Ares (see CADMUS). Dicaearchus, referring to the town of Cassander, gives two measurements for the circuit, equal to about 9 m. and 5½ m.; the smaller fairly corresponds to the 4½ m. over which the extant remains have been traced; it consisted of sun-dried brick on a stone foundation. Beyond this the topography is wholly uncertain. From the interest of the site in history and still more in literature, as the scene of so many dramas, the temptation to fix details has been specially strong. Conjectural plans or descriptions, differing widely, are given by Leake, Forchhammer, Ulrichs, Bursian, Fabricius and others (references below). There are two main difficulties to contend with. The description of Pausanias was written at a time when the lower city was deserted, and only the temples and the gates left; and the references to Thebes in the Attic dramatists are, like those to Mycenae and Argos, of little or no topographical value. The literary glory of Thebes is centred in the poet Pindar. It had a flourishing school of painting in the 4th century, of which the most famous representation was Aristides, who excelled in pathetic subjects.

THEBES, ROMANCE OF. The French *Roman de Thèbes* is a poem of some 10,000 lines which appears to be based, not on the *Thebaid* of Statius, but on an abridgment of that work. This view is supported by the omission of incidents and details which, in spite of the altered conditions under which the poem was composed, would naturally have been preserved in any imitation of the *Thebaid*, while again certain modifications of the Statian version can hardly be due to the author's invention but point to an ancient origin. As in other poems of the same kind, the marvellous disappears; the Greeks adopt the French methods of warfare and the French code of chivalric love. The *Roman* dates from the 12th century (*c.* 1150–55), and is written, not in the *tirades* of the *chansons de geste*, but in octosyllabic rhymed couplets. It was once attributed to Benoît de Sainte-More; but all that can be said is that the *Thèbes* is prior to the *Roman de Troie*, of which Benoît was undoubtedly the author. The *Thèbes* is preserved also in several French prose redactions, the first of which, printed in the 16th century under the name of *Edipus*, belongs to the early years of the 13th century, and originally formed part of a compilation of ancient history, *Histoire ancienne jusqu'à César*. The first volume of *Les histoires de Paul Crose traduites en français* contains a free and amplified version of the *Thèbes*. The *Romance of Thebes*, written about 1420 by John Lydgate as a supplementary Canterbury Tale, was printed by Wynkyn de Worde about 1500. From the *Roman de Thèbes* also were possibly derived the *Ipomedon* and its sequel *Prothesilaus*, two *romans d'aventures* written about the end of the 12th century by Hue de Rotelande, an Anglo-Norman *trouvère* who lived in Credenhill, near Hereford. The author asserts that he translated from a Latin book lent him by Gilbert Fitz-Baderon, 4th lord of Monmouth, but in reality he has written romances of chivalry on the usual lines, the names of the characters alone being derived from antiquity.

See L. Constans, *La Légende d'Oedipe étudiée dans l'antiquité au moyen âge et dans les temps modernes* (Paris, 1881), and in the section "*L'Épopée antique*" in De Julleville's *Hist. de la langue et de la litt. françaisc*; *Le Roman de Thèbes*, ed. L. Constans (*Soc. des anciens textes françois* (Paris, 1890); G. Ellis, *Specimens of Early English Metrical Romances*, iii. (1805).

THECLA, ST, one of the most celebrated saints in the Greek Church (where she is commemorated on the 24th of September) and in the Latin Church (where her festival is the 23rd of September). She is honoured with the title of "protomartyr." The centre of her cult was Seleucia, in Isauria. Her basilica, south of Seleucia, on the mountain, was long a very popular place of pilgrimage, and is mentioned in the two books of St Basil of Seleucia. The great popularity of the saint is due more particularly to her *Acta*, which in all their forms derive from the apocryphal work known as the *Acta Pauli et Theclae*. According to her *Acta*, Thecla was born of illustrious parentage at Iconium, and came under the personal teaching of the apostle Paul. In her eighteenth year, having broken her engagement with Thamyris, to whom she had been betrothed, she was accused by her relations of being a Christian. Armed with the sign of the cross, she threw herself on the pyre, but the flames were extinguished by a sudden rain. She then went to

Antioch, where she was exposed to wild beasts, then fastened to bulls in order that she might be torn asunder, and finally thrown into a pit full of serpents; but she was delivered from all these perils. She converted many heathen. Returning to Iconium, she withdrew into a mountain solitude, and became distinguished by many virtues and miracles. In spite of their highly fabulous character, which caused them to be more than once condemned by the Church, the *Acta* of Paul and Thecla, which date back to the 2nd century, are among the most interesting monuments of ancient Christian literature.

See *Acta Sanctorum*, September, vi. 546–568; J. A. Lipsius, *Acta apostolorum apocrypha* (Leipzig, 1891), i. 235–269; C. Schmidt, *Acta Pauli* (Leipzig, 1905), where an attempt is made to prove that the *Acta* of Paul and Thecla formed an integral part of the *Acta Pauli*; see also APOCRYPHAL LITERATURE. W. M. Ramsay, *The Church in the Roman Empire before* A.D. 170 (London, 1893), pp. 375 seq.; C. Holzey, *Die Thekla-Akten, ihre Verbreitung und Beurtheilung in der Kirche* (Munich, 1905). (H. DE.)

THEFT, the act of thieving or stealing. In English legal usage the practice is to call this act by its Norman-French name of "larceny," but properly theft is a wider term including other forms of wrongful deprivation of the property of another (see LARCENY).

The O.E. word *þeofðe* or *þiefðe* is formed from *þeof*, thief or *þeofian*, to thieve, cf. Ger. *Dieb*, Du. *dief*, Goth. *thiubs*. The origin is not known. It may be related to Lithuanian *tupēti*, to crouch or squat down; thus "thief" would mean "one who hides himself." The O.E. *stelan*, to steal, appears also in other Teut. languages, cf. Du. *stelen*, Swed. *stjäla*, Goth, *stilan*, &c. It has been doubtfully connected with Gr. *στερεῖν*, to deprive.

THEGN, or THANE, an Anglo-Saxon word meaning an attendant, servant, retainer or official, and cognate with Gr. *τέκνον*, a child. From the first, however, it had a military significance, and its usual Latin translation was *miles*, although *minister* was often used. J. Bosworth (*Anglo-Saxon Dictionary*, new ed. by T. N. Toller) describes a thegn as "one engaged in a king's or a queen's service, whether in the household or in the country," and adds, "the word in this case seems gradually to acquire a technical meaning, and to become a term denoting a class, containing, however, several degrees." The precursor of the thegn was the *gesīth*, the companion of the king or great lord, the member of his *comitatus*, and the word thegn began to be used to describe a military gesīth. It is only used once in the laws before the time of Aethelstan (*c.* 895–940), but more frequently in the charters. H. M. Chadwick (*Studies on Anglo-Saxon Institutions*, 1905) says that "the sense of subordination must have been inherent in the word from the earliest time," but it has no connexion with the German *dienen*, to serve. In the course of time it extended its meaning and was more generally used. The thegn became a member of a territorial nobility, and the dignity of thegnhood was attainable by those who fulfilled certain conditions. Thus from a document of uncertain date, possibly about the time of Alfred the Great, and translated by Stubbs (*Select Charters*) as "Of people's ranks and laws," we learn:—"And if a ceorl throve, so that he had fully five hides of his own land, church and kitchen, bell-house and burh-gate-seat, and special duty in the king's hall, then was he thenceforth of thegn-right worthy." And again—"And if a merchant throve, so that he fared thrice over the wide sea by his own means, then was he thenceforth of thegn-right worthy." In like manner a successful thegn might hope to become an earl. In addition to the thegns there were others who were thegns on account of their birth, and thus thegnhood was partly inherited and partly acquired. The thegn was inferior to the aethel, the member of a kingly family, but he was superior to the ceorl, and, says Chadwick," from the time of Aethelstan the distinction between thegn and ceorl was the broad line of demarcation between the classes of society." His status is shown by his wergild. Over a large part of England this was fixed at 1200 shillings, or six times that of the ceorl. He was the twelfhynde man of the laws, sharply divided from the twyhynde man or ceorl.

The increase in the number of thegns produced in time a subdivision of the order. There arose a class of king's thegns, corresponding to the earlier thegns, and a larger class of inferior thegns, some of them the thegns of bishops or of other thegns. A king's thegn was a person of great importance, the contemporary idea being shown by the Latin translation of the words as *comes*. He had certain special privileges. No one save the king had the right of jurisdiction over him, while by a law of Canute we learn that he paid a larger heriot than an ordinary thegn.

But, like all other words of the kind, the word thegn was slowly changing its meaning, and, as Stubbs says (*Const. Hist.*, vol. i.), "the very name, like that of the gesith, has different senses in different ages and kingdoms, but the original idea of military service runs through all the meanings of thegn, as that of personal association is traceable in all the applications of gesith." After the Norman Conquest the thegns appear to have been merged in the class of knights.

The twelve senior thegns of the hundred play a part, the nature of which is rather doubtful, in the development of the English system of justice. By a law of Aethelred they "seem to have acted as the judicial committee of the court for the purposes of accusation" (W. S. Holdsworth, *History of English Law*, vol. i. 1903), and thus they have some connexion with the grand jury of modern times.

The word thane was used in Scotland until the 15th century, to describe an hereditary non-military tenant of the crown. (A. W. H.*)

THEINNI, or HSENWI, one of the Northern Shan States of Burma. It is called by the Shans Hsenwi, and also officially so designated, but is better known by the Burmanized name of Theinni. It was by far the largest of the cis-Salween Shan states, and at one time included not only all the territory of the present states of North and South Hsenwi, but also Kehsi Mansam, Möng Hsu, Möng Sang, and Möng Nawng, besides having a sort of protectorate over Mang Lön and other Wa states east of the Salween. These had, however, fallen away in Burmese times, and at the period before the British annexation Theinni was divided into five parts by name; but there was no central authority, and the whole state was in hopeless disorder. This continued until the appearance of British troops in March 1888, when it was divided into two states—North Theinni, which was assigned to a successful adventurer, Hkun Sang, of Tôn Hông, and South Theinni, which went to Nawmöng, of the old Shan ruling house. North Theinni has an area of 6330 sq. m., and a population (1901) of 118,325 persons; estimated revenue, £6000. South Theinni has an area of 2400 sq. m., with a population (in 1901) of 67,836; estimated revenue, £4800.

The northern part of North Theinni is a mass of hills affected by the geological fault which has produced the rift that forms the Nam Tu or Myit-ngè valley, and has thrown up a series of parallel ranges which extend northwards to the Shweli (Lung Kiang), without altogether destroying the north and south trend which is the characteristic of the Shan hills as a whole. In the valleys between these hills are numerous tracts under rice cultivation, some circular or oval, some mere ribands along the river banks. The southern portion has much more flat land, along the line of the Nam Tu, its tributaries the Nam Yao and the Nam Nim, and the Nam Yek flowing into the Salween. This was formerly thickly populated, and still remains the most valuable portion of the state. A range running westwards from the Salween, and marking the southern border of the rift in the hills, divides North from South Theinni. Both north and south of the Nam Tu there are many peaks which rise to 6000 ft., and several over 7000 ft. The northern portion is almost consistent enough in its altitude of about 4000 ft. to be called a plateau. It has large, grassy, upland downs. This part of the state has fallen almost entirely into the hands of the Kachins. The Shans are found in the Nam Mao (Shweli or Lung Kiang) valley, and in the Nam Tu and other valleys in the southern part of the state. The line of the Nam Mao is the lowest portion of North Theinni, being little over 2000 ft. above sea-level. The southern valleys are about 500 or more ft. higher. South Theinni is practically bisected by the huge mass of Loi' Ling, nearly 9000 ft. above sea-level, and by the spurs which that peak sends north and south. Apart from this it consists of broken hill-country of no great height, or open rolling downs, the latter chiefly in the eastern half of the state. It is watered by numerous streams, of which the chief is the Nam Pang, an affluent of the Salween. The chief river in the northern state, apart from the Salween, is the Nam

Tu or Myit-ngè, which rises on the Irrawaddy-Salween watershed, not far from the latter river, and flows westwards through the state into Taungbaing or Thibaw, and eventually into the Irrawaddy at Amarapura. The Nam Mao or Shweli only skirts the state, but it receives a considerable tributary, the Nam Paw, which has its entire course in Theinni territory, and is large enough to be barely fordable in the dry weather, and only passable by boats in the rains. The deforestation caused by years of upland cultivation has dried up many of the springs, but as a whole North Theinni is very well watered. Considerable deposits of coal, or rather of lignite, exist in both North and South Theinni, but do not appear to be of high quality. Gold is washed in many of the streams in a fitful way. Limestone exists in large quantities. No valuable timber exists to any considerable extent. There is some teak in the Nam Yao valley, and scattered wood-oil trees exist. Pine forests cover some of the ranges, but, as elsewhere in the Shan states, varieties of the oak and chestnut are the commonest forest trees. The climate of the state as a whole is temperate. In the plains of the uplands there are yearly frosts in January, February and March, but in the greater part of the state the thermometer rarely falls to freezing-point, and in the hot weather does not exceed ninety degrees for any length of time. The average rainfall seems to be about 60 in. yearly. After the disruption of the ancient Shan empire at Tali by Kublai Khan, Theinni seems to have been the centre of the independent Shan kingdom, with various capitals in the Shweli and Nam Tu valleys. This kingdom of Kawsampi was ended by the Burmese about 1738, and the country was divided into various states, with appointment orders from Ava. Numerous rebellions and civil wars have reduced Theinni from its position as the most powerful and populous Shan state to a condition of fearful desolation. It has regained much population since the British occupation in 1888, but is still far from its old prosperity. Much may be expected from the cart roads that have been made, and from the Mandalay-Kun long Railway.

Hsenwi, the capital of North Theinni, stands near the north bank of the Nam Tu. The ruins of the old capital lie at a short distance, and show it to have been a large and well-built town, with a number of houses variously estimated at from three to ten thousand. Möng Yai is the capital of South Theinni, with a population of about 2000. Lashio, the headquarters of the superintendent of the Northern Shan State, is in North Theinni. The races found in Theinni comprise Shans, Kachins, Chinese, Burmese, Lihsaws, Wa, Palaungs and Yanglam. The Shans and Kachins vastly predominate, and are nearly equal in numbers. (J. G. Sc.)

THEISM (Gr. θεός, god), literally, and in its widest sense, the belief in a god or gods. The term has had several changes of meaning. (1) It appears for the first time in 18th-century English as an occasional synonym for "deism" (*q.v.*), and therefore as applying to those who believed in God but not in Christianity. Later criticism, orthodox and heterodox, upon the English deists inclines to charge them with the conception of a divine absentee, who wound up the machine of nature and left it to run untended. That was the general 18th-century way of thinking. God was apt to be thought of as purely transcendent, not immanent in the world. (2) In the 19th century theism is generally used of positive belief in God, either with or without belief in the claim of Christianity to be a revelation, but unassociated with any peculiarities of 18th-century deists. If the word "deism" emphasizes a negative element—rejection of church Christianity—"theism" generally emphasizes the positive element—belief in God. (3) There is also a third usage. "Theism" was reclaimed by Theodore Parker, F. W. Newman, Frances Power Cobbe, and others, for their more modern speculative belief in God, which, while non-Christian or at least non-orthodox, held to an immanent God, continually revealing himself—in the moral consciousness. The ambiguity cannot be cured. We use the word in this article in the second sense.[1]

Natural Theology.

I. From this point of view theism is a synonym for Natural Theology, or almost so. But the expression Natural Theology itself has a history. (1) The "three theologies"—recognized by the early Roman Stoics—probably on the suggestion of a passage in Aristotle's *Metaphysics*, xi. 8—are named by St Augustine (Latinizing the Greek terms) mythical, *natural*, and civil or political (*City of God*, iv. 27). There is probably a malicious echo in a well-known passage of Gibbon (*Decline and Fall*, chap. ii.): "The various modes of worship which prevailed in the Roman world were all considered by the people as equally true, by the philosopher as equally false, and by the magistrate as equally useful." Augustine rejects all three "theologies" as pagan figments, and not a few church writers follow him in this—borrowing his learning without naming him (*e.g.* the Protestant Grotius in his notes on Rom. i. 20). Yet the natural or physical theology of the philosophers—in contrast to mere myths or mere statecraft—seems a straightforward effort to reach faith in God on grounds of scientific reason. It deserves the name, in the modern sense, of Natural Theology. (2) Raymond of Sabunde's *Liber naturae sive creaturarum* (1434–36) bears also the title *Theologia Naturalis*—but not from the author's own hand,[3] though his introduction to the book in question, the *Prologue*, put upon the Index at Rome for its daring, describes the "book of nature" as "connatural to us," in contrast with the "supernatural" book, the Bible, which belongs to the clerics. Laymen may read the book of nature, and Man himself is the most important "leaf" in it. Raymond attempts to demonstrate the whole of church theology upon principles of reason. That is a task quite beyond what is generally recognized as Natural Theology. (3) With Francis Bacon (*Advancement of Learning*, 1605) the expression Natural Theology emerges in what has become the modern sense—as standing for a part of Christian theology, attainable by reason, and contrasted by most theologians with the "mysteries" of faith (Bacon uses that term too) on the principles of Albert the Great and Thomas Aquinas (see APOLOGETICS).

[It is not clear that Bacon is the first to use the term in the now accepted sense; but he and Theophilus Raynaudus, S. J., in his *Theologia Naturalis* (1622), of which there is a copy in the Bodleian, must at least be among the first in their respective communions to do so. Raynaudus's authorities, in favour of the recognition of a natural theology and against it, do not, so far as the present writer has been able to consult them, use the expression. So too H. Alsted, an early Protestant writer on Natural Theology (in his *Methodus Theologiae*, 1611, and in later works), defines it as moderns do—some of the *contents* of his Natural Theology are fantastic enough—and *his* authorities, again so far as consulted, differ upon the place to be assigned to Natural Theology within a system of study, but do not employ the term.]

Roman Catholic grouping.

In later times the expression is common; it is used *e.g.* by Locke, Leibnitz and Wolff. Wolff's influence made the usage habitual,[4] though Schleiermacher and Ritschl, like the Socinians earlier, deny the existence of a natural theology. Following the text and ordinary interpretation[5] of Aristotle's *Metaphysics*, it is believed that Aristotle already identified metaphysics with a theology: accordingly modern Roman Catholic learning, which owes a great debt to Aristotle through the schoolmen, includes Natural Theology in philosophy, not in theology properly so called. With Natorp's article W. Wallace's *Gifford Lecture*,[6] chap. i., may also be consulted; but Wallace does not distinguish the unusual sense which the term bears as applied to Raymond's book. R. Flint has remarked that Natural Theology ought not merely to *prove* the being of God, but to give a full systematic view of what (it is contended) can be learned of theological truth from the "light of nature" (St Augustine, and

[1] Imm. Kant's distinction of "deist" and "theist" may be found in the *Critique of Pure Reason*, "Transcendental Dialectic," Book II. chaps. iii. and vii. It is curious, but, unless for the study of Kant, unimportant.

[2] Cf. THEOLOGY. Natorp's article quoted there gives the reference to the passage in Aristotle, but does not recognize its connexion with the later Stoical distinction.

[3] See art. "Raimundus Sabiende" by Schaarschmidt in Herzog-Hauck, *Realencyklopädie* (ed. 1905). At this point we must also call to mind the wide currency given to the term theology by Abelard, and his editors or copyists.

[4] A. Harnack and some others use the expression in a wider sense. Any supposed principles (even if not worked out into a system of inferences) used as ready-made clues for the study and interpretation of Christianity are described by this school as natural theology (cf. THEOLOGY).

[5] Challenged by Natorp; see THEOLOGY.

[6] Published in *Lectures and Essays*.

theologians generally after him). The name "theism" makes that requirement less emphatic (see below).

Another kindred term is "Natural Religion." We meet with this in the titles of two Latin works[1] by German authors in reply to Lord Herbert of Cherbury. They use it with strong condemnation, from the standpoint of rigorous Christian orthodoxy; but it comes into England within very few years upon the Christian side—religion against irreligion—in Bishop John Wilkins's *Principles and Duties of Natural Religion* (1678). The author died 1672, and left the book unfinished; but the language of the title occurs in the first sentence; so it is undoubtedly Wilkins's, as well as sanctioned by his editor and connexion through marriage, Tillotson, afterwards the archbishop. We meet with "Natural Religion" again in Samuel Clarke's works, and notably in Bishop Joseph Butler's *Analogy* (1736). Thus, as employed by most writers, "Natural Religion" connotes neutrality or even friendliness towards Christianity; just as is the case with theism in sense (2), or with Natural Theology. "Deist," or sometimes "theist" in sense (1), or Naturalist, is a term of reprobation with English 18th-century apologists, but not "Natural Religion." If there is any difference between "theism" or "Natural Theology" on the one hand, and Natural Religion on the other, it is to be found in the more practical character attaching to natural "religion." While Romans i. 19 and 20 (yet cf. Acts xiv. 17, xvii. 24, &c.) is the main New Testament passage which seems to recognize a Natural Theology, Rom. ii. 14, 15 may be said to assert Natural Religion. When the expression Natural Theology comes to the front once more with Archdeacon W. Paley (1802), this is a sort of after-birth or anachronism.[2]

Natural Religion.

Natural Law.—We do not pretend that Law of Nature—the jurist's term, not of course that of inductive science—is strictly a synonym for theism. But it is a cognate conception, of great importance historically, bearing the marks of the Stoic doctrine of "nature," and helping to turn men's minds towards a "natural" theology. A pantheist may believe in Law of Nature and go no further; a theist who accepts Law of Nature has a large instalment of natural theology ready made to his hand; including an idealist, or else an intuitionalist, scheme of ethics. Both *jus naturale* and *lex naturalis* are as early as Cicero, and the *jus gentium* of the Roman lawyers is earlier still. Ambrose of Milan (*Epistles* ix. 71) quotes Romans ii. 14, 15—the passage already referred to, under "Natural Religion"—as asserting "Natural Law"; St Paul's words suggest that form of thought and may conceivably have been suggested by it. J. G. Ritchie's *Natural Rights*, from the point of view of a very hostile (evolutionary) idealism, sketches the early history of the phrase Natural Law.[3] The philosopher in Abelard's *Dialogus inter Judaeum Philosophum et Christianum* expects to be saved *ex sola lege naturali*; here "law of nature" is fully equivalent to Natural Religion, and the word *sola* sets it in contrast with Christianity. Not to speak of the canonists, Thomas Aquinas gives natural law an important place; while Melancthon, drawing from Aquinas, gives it an entrance into Protestant thought. Zwingli and Calvin on the other hand prefer the positive view of law as instituted by God far back in history in the days of the Old Covenant; but, when exegesis or controversy puts pressure upon them, they fall into line and reiterate the appeal to a Natural Law. Richard Hooker, again with traces of Aquinas, uses the conception as a weapon against Puritanism, with its aggressive positivism of scriptural precept. Natural Law, he claims, leaves room for discretionary arrangements like episcopacy; Scripture does not mean to supersede the light of reason. It is intelligible that Locke (*Treatises of Civil Government*) should have a relish in quoting Hooker against the divine-right royalism of Sir John Filmer; but in Locke there is already a revival of belief in the (beau-ideal) "state" of nature and a growing emphasis upon natural *rights*; ideas which, heralded by Rousseau, echoed round the world in the French Revolution. Locke had spent some years in Holland, the country of Grotius, who, with help from other great lawyers, and under a misapprehension as to the meaning of the Roman *jus gentium*, shaped modern concepts of international law by an appeal to law of nature.[4] This moral ideal rendered considerable services to civilization; we must not forget these, in the offence which the myth of a primitive golden age may offer to our historic sense. The kernel is sound enough though the husk is a poor thing. Finally, it is of some interest to note that Chr. Wolff, in the intervals of his chequered theological career, lectured and wrote as a jurist upon the Law of Nature.

Natural Law.

"Philosophy of religion" is the modern term. It again is not exactly a synonym, though more nearly so than the last. The new phrase indicates that we are to approach the thought of God through a study of religious beliefs and practices; "theism" tended to make God a purely scientific inference from the facts of nature. But "philosophy of religion" can be construed in many different ways. An investigator, pledging himself to no beliefs—even perhaps one who definitely disbelieves and rejects theism—may yet interest himself in tracking out the psychology of religion. Or a philosopher like Hegel, armed with a metaphysical theory, may descend upon the facts of religion and interpret them in its light, till they almost lose their original significance, which we might provisionally define as consisting in this, that the believer in any religion finds himself helped or (as he claims) saved by it. Again, we must not be misled by verbal idiosyncrasies. What James Martineau calls *A Study of Religion* is really in the main a re-statement of old theistic arguments.[5]

Philosophy of religion.

[Wallace's *Gifford Lecture* may be consulted upon this phrase also. He observes with truth that Natural Theology, if you remove from it the idea of subordination to Christianity as (claiming to be) a special revelation, tends to pass into a philosophy of religion. But it does not follow that the new standpoint involves what Wallace seems to hint, though he conceals his meaning behind complimentary rhetoric—rejection of church Christianity. A. M. Fairbairn's *Phil. of the Christian Religion* shows by its very title that an effort is being made to combine great confidence in metaphysics with strong belief in the uniqueness of Christianity; and the effort will be found to characterize all Fairbairn's work. Possibly, fuller study of religions may help theologians to formulate the imperial claims of Christianity more happily than in the dry contrast between what is "revealed" and what is "natural." But that contrast is traditional; and it is implied in the ordinary theological usage of such phrases as "natural theology" or "natural religion" and almost of "theism."]

Comparative religion, or, as some call it, history of religion, is yet another modern study, closely akin to the last discussed, although more strictly confined to registering the sequence of religious phenomena and less disposed towards criticizing religions or towards ranking them in an order of merit. We cannot, therefore, call it precisely synonymous with theism. And yet theism—or monotheism—constitutes a special *locus* in the history of religion. The historian observes and records, in different lands and ages, the rise or explicit utterance of belief in one God.

Comparative Religion.

Some uncertainty may be felt whether pantheism should rank as a theism. Is unity the main point? Or is not personality rather of prime importance, though doubtless presupposing unity? (Usage does not allow us to rank polytheism as a form of theism.) E. Troeltsch, *Kultur der Gegenwart*, Teil I. Abt. 4, p. 470, finds that the wisdom of the priests, in one land after another, rises to the thought of divine unity. That suggests pantheism, the usual form of such esoteric wisdom. Professor T. W. Rhys Davids (*American Lectures*, p. 37) sums up that, when the name of an earlier deity is

[5] See his *Introduction*.

attached to the object of supreme worship, monotheism proper is approached; while, when a new thought-construction is put in the supreme place, there is a tendency rather towards pantheism. So far as this is true, theism (proper) would seem to be an accident of language.

There is a further problem; whether monotheism is of very early occurrence. Belief in a primitive historical revelation, once universal among Christians, has almost disappeared; but belief in a very early and highly moral theism is stoutly defended, chiefly on Australian evidence, by Andrew Lang (*The Making of Religion* and later works). If Lang is right, "primitive" peoples drew typical theistic inferences, and argued to God from nature and from conscience, though without displacing other types of religious belief and practice. In many regions—Egypt, Babylonia, &c.—individual investigators of the great religions have thought they found traces of an early—one hesitates to write, of a "primitive"—monotheism. Perhaps J. Legge, who finds true theism at the dawn of Chinese history, is the most authoritative representative of such views.

Brahman theism.

Passing to later times, we can watch a theory of monotheism rising, and dying down again, during what our scholars distinguish as the Brahmanical period of Indian religion. The supreme god, Isvara, has the personal name Prajapati, Visvakarman or some other. But this theism is lifeless—a "pale and shallow deism, which India has often confessed with the lips, but which has never won the homage of her heart."[1] The thought of India is upon the side of pantheism. Again, the heretical Egyptian king Amenophis IV. or Akhenaton, one of the sovereigns to whose government the celebrated Tell el-Amarna letters from Palestine were addressed, was a zealous champion of the exclusive claims of the sun-disk God, Ra; but his policy died with him. In Babylonia a mutilated inscription printed by T. Pinches (*Transactions of Victoria Institute*, vol. 28), identifying (so far as preserved) thirteen other Gods with Marduk, has been hailed by Friedrich Delitzsch (*Babel und Bibel*) as the great fountain-head of monotheism, and has influenced the bold if highly precarious conjectures of H. Winckler.[2] Of more assured importance was the Zoroastrian faith—"pure moral dualism if not theism" (L. H. Mills)—which proved its zeal by persecutions. But later times nearly strangled Zoroastrian piety, not only by laws of ritual purity but also by newly evolved secondary deities—personified attributes, and the like. So that here again theism, if theism it was, did not continue in strength. If we understand by theism not simple belief in a divine unity, but such faith in one divine person as will constitute the basis for a popular religion, then—unless we allow a doubtful exception in Zoroastrianism—we must agree with those historians of religion who affirm that the world has known only a single living monotheism, viz. that of the Old Testament, along with what are historically the daughter faiths, Christianity and Islam.

Egyptian. ***Babylonian.*** ***Zoroastrian.***

Incomplete theistic impulses.

The theist believes that he can further trace many incomplete workings of the monothesitic instinct in the history of religion. Not only is it true, as A. Menzies observes, that "Reason knows only God, not Gods"; if we take religion as *saving help*, no worshipper possesses religion in full security until he has gone straight to the fountain-head, and gained the friendship of the God of Gods. Indian Vedic henotheism (otherwise called kathenotheism);[3] Semitic monolatry, so important as the probable starting-point of religious development in Israel; the Greek use of "Zeus" almost as we say "God"—even the attempt to arrange deities in a monarchical pantheon, all show the tendency, though it so seldom attains a real victory.

[1] A. Barth, *Religions of India*, Eng. trans., pp. 29, 30, 69. We may probably extend this hostile judgment to the theism of the modern Samaj-es.

[2] The centralizing of worship at Babylon by its last king, Nabonidos, hardly seems to have amounted to monotheism.

[3] The two terms are explicitly identified by F. Max Müller, their inventor (*e.g. Hibbert Lectures*, chap. vi. p. 271).

Subordinate elements of theism.

II. We have already suggested that theism covers more ground than the name at first may suggest. It can never quite confine attention to the problem of the being of God. Where God is believed in at all, it is believed that upon God everything else depends. With the thought of God, accordingly, there is correlated a modification in thoughts upon all other subjects; and a full system of theism must discourse "Of God, of the world, of the Soul," like Matthew Arnold's Moses. In other words there must be doctrines regarding matter and mind, the world and the self, as well as regarding that Absolute Being who is believed to exist behind both, revealing Himself through them. This way of approaching theism is illustrated in A. C. Fraser's Gifford Lectures, or in earlier times in the writings of Christian Wolff, whose sciences, according to the slightly different nomenclature which Kant imposed on them, were "rational psychology," "rational cosmology," and "rational theology." Kant swept away, so far as his influence extended, such "dogmatic metaphysics" and the old-fashioned theism which it constituted or included; but Kant himself introduced, in his own more sceptical yet also more moral type of theistic doctrine, a new trichotomy—God, Freedom, Immortality, the three "postulates" of the "practical reason." It is tempting to try to correlate the members of this triad with the individual members of the older triad. But that would only mislead us; free will and immortality are really predicates ascribed—on whatever grounds—to the soul; and it is natural that in theism the soul of man should be a topic second in importance only to God Himself. Every theistic system, or almost every one, makes provision in some way for Kant's three postulates. Accordingly, even in a hurried survey of the history of theism, we must try to question the systems we are reviewing upon their attitude towards human freedom and immortality, as well as upon their doctrine of God. Sometimes it will be found that free will is asserted as an assured fact, as a *datum*, and so as a ground of inference to God. But sometimes free will is rather a *probandum*. In Christian theology, much labour has been spent upon vindicating man's freedom against God's intrusion, or upon blotting out human power in order to leave room for the divine. Theism suggests at the very outset that we should rather expect to find a correlation between the two. If there is a God at all, he must be thought of as the guarantee of freedom in man and as the pledge of his immortality.

Kant's "postulates." ***Free will.***

Simplification of theism.

The mention of Christian theology may remind us that, for the majority of theists in medieval and modern times, theism proper has ranked only as a secondary wisdom. It is possible for Christians to work out natural theology in separate detail; but we cannot wonder if they rarely attempt the task, believing as they do that they have a fuller revelation of religious truth elsewhere. In point of fact, as we look to history, we find that theism has been much simplified and cut down. First of all, attention has been concentrated upon God. One does not suggest that this concentration was an error. On the contrary, even Christian theology makes at least the effort to show that the thought of God regulates the whole system of belief. Yet while an adequate doctrine of God may settle everything *in principle*, we ought to remember that there are *applications* of the principle, apart from which we do not see our way clearly. As a second step in concentration, attention is almost confined to the question "Does God exist?" and to theistic proofs as answering "Yes." The further question "What is God?" is slurred, as if there could be no two opinions regarding that; whereas in truth there are two hundred opinions. A. B. Bruce feels this so strongly that the natural theology section of his *Apologetics* entirely omits the question "Does God exist?" in favour of the question "What is God?" Perhaps that is equally one-sided. When we do find theism dealing with the question "What is God?" it tends to borrow from scholastic forms of Christian theology the scheme of Being and Attributes (see *e.g.* Wolff). But such a scheme gives at best an external preliminary description of the object to which it is applied.[1]

So our wealth of material narrows down in the ordinary handling to a single question. God, the world, the soul, free will, immortality, optimism; *What* then is God? All these questions, and perhaps others, tend to conceal themselves behind a single discussion: Does God exist? But further still. Either the fuller or the narrower way of dealing with theism will differ according to the philosophical standpoint of the particular theist who speaks to the question. As long as the battle of the philosophies endures, theism can hardly be unified. Its history is not so much that of a single evolving doctrine, but rather the history of many and diverse theistic schemes.

Difference of philosophical standpoint.

III. It may help us if we rapidly review at this point the leading types of philosophy in their application to the theistic problem. Grouping and naming are fixed here for one special purpose. From other points of view they may perhaps appear open to blame; but it is hoped they will throw light upon our present study.

The simplest basis for philosophy[2] is empiricism. Such a philosophy makes little serious attempt at constructive work in antiquity; but, upon the first great victories of physical science in modern times, a desire arose to extend the new and wonderfully fruitful method to the ultimate problems of speculation. Let us take experience as our teacher! Let us stand upon realities—upon facts! Difficulty may be found in carrying out this empiricist programme; but at the outset no one dreams of failure. Beginning with the certainties of everyday experience, it reaches theism at last by means of an analogical argument. Many objects in nature, organisms especially, seem to resemble the works of human *design;* therefore with high probability we infer a designing mind behind nature, adequate to the production of these special results.[3] Having got such a mind, we may next inquire whether, on the principle of parsimony, it will not account for more; perhaps for everything in nature! But the starting-point of the argument in question is the purely empirical evidence of a single fact or set of facts; it proceeds by way of analogy, not of strict demonstration; and it claims for its results nothing more than probability. From Socrates, in Xenophon's *Memorabilia*, downwards, the argument is tolerably common; it is notable in Cicero; in the modern discussion it dominates the 18th-century mode of thought, is confidently appealed to though not worked out by Butler, and is fully stated by Paley. The argument does not necessarily imply empiricism in philosophy; still, it is peculiarly characteristic of empiricism. In ethics empiricism begins by recognizing that man possesses sensations, and so is liable to pleasures and pains. Hence, early empiricism makes ethics simply a calculus of pleasures ("hedonism"). We may doubt, with W. E. H. Lecky,[4] whether such a philosophy affords a basis for natural theology at all; but the attempt is made. As J. S. Mill tried to reconcile criminal law and its punishments with his very hard type of determinism by saying that law was needed in order to weight the scale, and in order to hold out a prospect of penalties which might deter from crime and impel towards good citizenship, so Paley held that virtue was not merely obedience to God but obedience "for the sake of eternal happiness." A second type of hedonism—less ignoble, but perhaps also less logical—calls men to seek the happiness of *others*. Paley includes that too; virtue is "doing good to mankind," in obedience to God, for the sake of heaven.

Empiricism.

Argument from design.

Ethics; Hedonism.

The second type of philosophy, for our purpose, is intuitionalism. It finds its chance in the misadventures of empiricism. The Scottish philosophy of Thomas Reid and his successors believed that David Hume's scepticism was no more than the genuine outcome of Locke's sensationalist appeal to experience when ripened or forced on by the immaterialism of Bishop Berkeley—God and the soul alone; not God, world and soul. And so the Scotsmen fell back upon the witness of consciousness. They did not make much use of the word "intuition," which may indeed be taken in different senses, *e.g.* of visionary experiences as well as of the principles of "common sense" (*i.e.* universal beliefs). They spoke of "natural realism" and a "natural dualism" of mind and matter (reinstating here the element which Berkeley had struck out). Still, they do not repudiate the word "intuition," and kindred writers make it prominent. The term is borrowed from Sight, of all the physical senses the one which most rapidly instructs the mind. You see, at a glance, that things are so. Indeed, there is a further implication, when the term intuition is borrowed for mental vision; you see at a glance that things *must be* so. Here then characteristically intuitionalism occupies a half-way house between empiricism, with its appeal to real given fact, and idealism, with its appeal to necessity. The senses, in perception as contrasted with sensation, are held to give immediate knowledge. We perceive, beyond all possibility of doubt, that things *are* so and so. This is Reid's first reply to Hume. Define more carefully than Locke did, with his blunder about "ideas," the process of perception, and you cut up scepticism by the roots! So far, this philosophy has little bearing upon theism. But Intuitionalism has further arguments for the doubter. Besides testimony from outer sense, we have testimony and teachings from consciousness within—"first principles," as Reid generally calls them. There are some principles which, as soon as they are presented to the mind and correctly grasped, must be assented to; we *see* the truth! Two regions become prominent in the working out of intuitionalism, if still more prominent in the widely differing philosophy of Kant—the regions of mathematics and of morals. Though J. S. Mill boldly affirmed that there might be remote realms in space where $2+2$ did not make 4 but some different total, even empiricists may hestitate to concur; and yet Mill's assertion is at least the most obvious empiricist reading of the situation. If all knowledge is drawn from experience, statements universal in form are but generalizations, holding within the limits of actual experience, or advanced beyond them at our peril. Geometry again is regarded by thoroughgoing empiricists as hypothetical. It deals, according to Mill, with arbitrary and imaginary constructions. If there were such a thing as a triangle contained by absolutely straight lines, its three angles would no doubt measure what Euclid says; but straight lines and true triangles nowhere exist *in rerum natura*. Kant's point is ignored, that deductions from these "imaginary" figures *apply* to the "real" world of experience. Every time we survey a field, we go upon the principles, not of special experience, but of *a priori* necessity. Given certain linear and angular measurements, the area *must* be so and so. Great as is the difference when we pass from mathematics to morality, yet there are striking similarities, and here again intuitionalism claims to find much support. If we accept moral ideals at all, we are no longer in the world of mere phenomenal sequences, but in a new world. It is a problem for empiricism; given a world where nothing but phenomenal sequences exist, to account for moral ideals. Vulgar materialism sneers at the problem; duty is a fraud or hobgoblin, a mere superstition. Even Jeremy Bentham, restive under appeals to vague and intangible standards, breaks out in despairing indignation against the word "ought" as "the talisman of arrogance, indolence

Intuitionalism.

[1] Criticism of the scheme, from the point of view of an idealist theism, will be found in John Caird's *Introduc. to the Phil. of Religion*, chap. viii. Yet the formula is serviceable. Perhaps it is even indispensable as a preliminary statement. We find it substantially revived in the opening sentence and general scheme of a useful book, A. Caldecott's study of *The Phil. of Relig. in England and America*.

[2] An outline of the history of theism is reserved for Section IV.; but it has not proved possible to sketch the types of philosophy without introducing references to the history of philosophy and sometimes even to the history of theism as well.

[3] Of course the Design Argument is well known in antiquity, but not the type of philosophy which stands or falls by that line of "proof."

[4] Cf. *Hist. of European Morals*, pp. 58, 59.

and ignorance," and as "an authoritative imposture."[1] Later ethical empiricism is more refined. J. S. Mill recognizes an ultimate difference in quality between higher and lower pleasures. A. Bain finds that benevolence is one given element in man's original constitution. H. Sidgwick holds that intuition must justify the claims of the general happiness upon the individual, though everything subsequent is hedonistic calculus. Herbert Spencer finds that the modern individual has intuitions of duty which represent the inherited experience of what has been good for the race in the past. Sir Leslie Stephen finds that moral laws are the conditions needful for the good of the social organism, and are imposed as such by society upon its individual members. The problem has altered its form. What the modern empiricist needs is a rational bond uniting the individual with the community or with the aggregate of individuals—a rational principle distinguishing high pleasures from low, sanctioning benevolence, and giving authority to moral generalizations drawn from conditions that are past and done with. The non-empirical moralist will not of course admit that duty to the community or to mankind is a final definition of the ethical ideal. He will accept it as a stage, of no small importance, in progressive definition; but he will seek to go further.

Criticism of intuitionalism.

We have already remarked that the difficulties of empiricism constitute the strength of intuitionalism. A critic of intuitionalism might add that they are its whole strength; intuitionalism is sound upon the intellectual and moral *interests* of humanity, but it does little to justify them. It reasserts them, with resolute loyalty; but if philosophy ought to vindicate, to explain, perhaps incidentally to modify, even, it may be, to purify our primary beliefs, intuitionalism is hardly a philosophy at all. For good or for evil, so far as there is an accepted line of theistic doctrine, that doctrine is intuitionalist. Other schools of philosophy pay flying visits to theism; intuitionalism is at home there. Its leading argument is the cosmological, concluding to "God as cause" (Martineau). When David Hume (*Dialogues concerning Natural Religion*) protests that the universe is a "singular effect" and that we have no right to affirm a cause for it, unless we have experience of the origin of many universes, and can generalize the conclusion, They all have causes—he may be unassailable upon empiricist grounds. But intuitionalism claims to allege a higher certainty; everything (or every change) *must* have a cause—this is not merely actual fact but necessary truth. The universe exists—or, as otherwise stated, the universe is "contingent"—therefore, even without detailed knowledge of different universes, we can affirm that it must be caused, and in its "Great First Cause" we recognize God.[2] It is generally stated that this argument was for the first time definitely formulated in Aristotle's philosophy. Of course the cosmological argument is rarely or never left to stand quite alone. The design argument is available for the slightly bolder philosophy of intuitionalism as well as for empiricist theism. But there is yet another argument which is even more important. Moral elements must enter into theism at some point: and, as against empiricism, intuitionalism is morally strong. Hence it naturally has a moral argument in reserve. Moral law implies a law-giver; "we are conscious of moral dependence" (Robert Flint). Still the main weight of intuitionalist theism rests upon the conception of God as First Cause.

As a philosophy, intuitionalism leaves the mind in all the embarrassment of an indefinite number of separate starting-points. Every percept is such a starting-point; it is an immediate certainty, remaining with us unmodified as the basis of reliable inference. Every First Principle of the mind is a starting-point too. Reid—certainly a very unsystematic thinker—furnishes long and random lists of "first principles"; a later writer, J. M'Cosh, in his *Intuitions of the Mind*, attempts a more systematic study. (For ethics we may also compare Miss F. P. Cobbe. Contemporary with Reid and even more popular in treatment was James Beattie; Dugald Stewart with trivial modifications followed Reid; but in Sir W. Hamilton and H. L. Mansel there were sweeping changes in the direction of agnosticism—changes due partly or primarily to the influence of Kant.) Memory is included among First Principles. Testimony is also a First Principle (this is aimed against Hume's *Essay on Miracles*). Inevitably the question forces itself upon the mind, is not some fuller synthesis possible? All these isolated starting-points of thought are said to be, one by one, necessary. Is there no higher or broader necessity? Can we not attain to some farther-reaching philosophy?

A transition to idealism or scepticism.

If we answer "Yes" to that question, we pass on from intuitionalism to idealism—an idealism not on the lines of Berkeley (matter does not exist) but of Plato (things obey an ascertainable rational necessity). This third possibility in philosophy does not enter at all into Lecky's grouping referred to above; in fact, it is very generally strange to older British thinking,[3] which, if it conceives any *tertium quid* besides empiricism and intuitionalism, is apt to think of scepticism. The fixed given points of intuitionalism furnish Hamilton with one of his arguments in his unexpected development towards a sceptical or "faith philosophy." You cannot prove any first principle. You accept it by "faith." So—for this among other reasons—we infer that knowledge has narrow limits, beyond which doubt, or faith, presently begins. But is it really a matter of faith that two and two make four? Do we "believe where we cannot prove" that the whole is greater than its part? A less sophisticated intuitionalism would rejoin with great force, "These are matters of *sight;* it could not be otherwise, and you *see* that it could not!" Hamilton's line of thought may, however, impress on us the conviction that it is extremely natural for philosophy to pass beyond the limitations of a purely intuitionalist programme. It does so notably in Kant.

Kant as a transitional idealist.

He is a most difficult writer; different readers understand him differently; and he uses in the earlier parts of his *Critique of Pure Reason* much of the language of intuitionalism. But nothing is more certain than that his thought is a strong solvent of the intuitionalist way of thinking; and he has had an immense influence in many directions. We may state his chief results in our own words. First he breaks up the percept. It is no ultimate given point of departure; it is due to the reaction of thought upon sensation. Sense alone will never create orderly experience, as empiricism supposed; but a group of sensations reacted on by thought does so; it becomes, it is, a percept. Secondly: the "forms" of time and space, not referable to any sensation, and presupposed in every experience, come from the mind ("Transcendental Aesthetic"). Thirdly: we cannot explain how these three elements—sensation; time and space; thought—work together. True, Kant refers often to the ideal of a "perceptive" or "intuitive understanding," whose thought would produce the whole of knowledge out of its native contents. But our understanding, he is convinced, is of a different and inferior type. Incomprehensibly, we are dependent upon sensation; and incomprehensibly, we place our sensations in time and space. Fourthly: if we try to think of objects *not* built up out of sensations and *not* in time and space, we are

[1] *Deontology*, p. 42. F. H. Bradley (*Ethical Studies*, p. 2) quotes an even plainer attack on the conceptions as well as the terminology of ethics in a *Westminster Review* article (Oct. 1873, p. 311) which describes "responsibility" or (*sic*) "moral desert in the vulgar sense" as "horrid figments of the imagination."

[2] Any attempt to treat "cause" as pointing to a truth here, but inadequately, would lead us beyond intuitionalism into some phase of idealism. To revise one's first principles is to be an intuitionalist no longer.

[3] Austin's *Jurisprudence* explicitly assumes that the dilemma of "intuitive" and "utilitarian" is exhaustive. Hence F. H. Bradley's characteristic protest (*Ethical Studies*, pp. 82, 83): "If we wished to cross an unknown bog, and two men came to us of whom the one said 'Some one must know the way over this bog, for there must be a way, and you see there is no one here beside us two, and therefore one of us two must be able to guide you. And the other man does not know the way, as you can soon see: therefore I must'—should we answer, 'Lead on, I follow'?"

baffled by contradictions or absurdities. Kant admits that we necessarily aspire to think of such objects—"God, the World, the Soul"—possibly this alleged tendency of our thought is already implied in the dream of a "perceptive understanding." But speculative knowledge breaks down or breaks off at an earlier point. If we try to know the soul, we grasp at a phantom. The self is always subject in consciousness and never can become an object of knowledge ("Paralogism of Pure Reason"). If we try to know the real world, we find ourselves distracted by opposite arguments ("Antithetic of Pure Reason"), plausible and resistless in attack, helpless in defence. The only thing which the "Ideas" of "Reason" can do for theoretic knowledge is to exert a "regulative" function. They teach the inferior but working part of our intellect, the "Understanding," that its picture of sensuous reality envisaged in time and space must be as fully articulated as is possible—as much differentiated into detail, and as perfectly integrated again into unity and system. God, for Pure Reason, is an illegitimate personification of the idea of perfected experience ("Ideal of Pure Reason"). Fifthly. there are fixed limits to the possibility of improving the quality of experience. Sense-knowledge is an endless process, inconsistent with the requirements of thought. We can by no means regard the physical world as the real world. But we possess knowledge of the physical world and of it alone. "Things in themselves"—whether defined by Kant, illogically enough, as causes of sensations, or again defined by him as the ultimate realities towards which thought vaguely points—in either case, "things in themselves" are unattainable by any definite knowledge. Our "reach" exceeds our "grasp" with a vengeance.

Kant's practical certainty.

So far as a remedy for scepticism is found at all, Kant places it, not within theoretic knowledge, but in moral or "practical" experience. Pure knowledge, for man, moves among a world of shadows; duty is certain. Mansel charged Kant with inconsistency in this preferential treatment of the moral consciousness; all our knowledge, even in moral things, was "relative" and was "regulative."[1] But, whether consistent or inconsistent, Kant was deliberate in differentiating between the ethical and the theoretic knowledge of man. "Analytic" or tautological thought does not become "synthetic" or capable of embracing a real content except under the sting of sensation; why sensation should thus help it is obscure, yet the fact is plain. But analytic thinking is victorious in morals, where the test of *formal self-consistency* distinguishes virtue from vice. The good man is the perfectly rational or perfect self-consistent man; and that is a full account of virtue, though Kant professes to re-interpret it still further in a much more positive sense as implying the service of humanity. True, at a later stage, the opposition of sense and thought reasserts itself strongly with Kant even in ethics. We are allowed moral certainty, but are forbidden the hope of genuine moral victory. Just as our knowledge never can finish its task of reducing world-experience to an intelligible system, so our will is never once able perfectly to obey the law of reason. There is always a taint of feeling in man's goodness. This portion of the ethical theory does curious service in Kant's doctrine of religion. That doctrine runs, briefly, as follows. Duty must be accepted as a given certainty, or it is vindicated—unsatisfactorily enough, perhaps—in the way just explained. Next, from the certainty of duty we infer as our first moral postulate free will—"I can because I ought"; which, primarily at least, means "I know I can because I know I ought." But this strong assertion is greatly qualified when Kant recurs to what he considers the least discredited portion of our theoretical knowledge. In the world of phenomena, not freedom rules but determinism. Causality is one of the "categories" which our mind uses in building up orderly experience. So we are left with a see-saw. Will is noumenally free; but phenomenally, in all real exercises of will, we are determined by the past. Secondly: from the discrepancy between the pure abstract law of self-consistent reason and the pleasure-tinged nature of man, we infer or postulate Immortality. As we never can hit the bull's eye, we must have literally endless opportunities of aiming at it, so as to get indefinitely nearer the central spot. If we did hit the exact mark, apparently we need no longer be immortal. Lastly, God. We must not, we dare not, aim at happiness. It is an eternal weakness in our moral being which makes us constantly squint aside from the thought of duty towards the forbidden motive—wincing under pain, or hungering after joy. Yet, if the motive is forbidden us, it is plain from another point of view that good persons ought to be happy. And, as nature reveals no great care for this postulate, we must appeal away beyond nature to a power who shall make good men at the last as happy as they deserve to be. And this power is God. Such is the train of thought as stated for us in the *Critique of Practical Reason.*

Later form; Critique of Judgment.

In the *Critique of Judgment*, Kant restates his new type of theistic argument in a way which has had great subsequent influence. We must conceive nature as overruled by God not so much for the sake of man's happiness as for the sake of his moral development. Or, to state this as a theistic argument: we are bound to postulate a God who overrules nature for moral ends. This new statement has at least the merit of bringing God into touch with man's goodness as well as with his happiness. But the train of thought is deeply embedded among characteristic sceptical hesitations. In spite of the various details of the *Judgment* Critique (as to beauty; and as to the "internal" or as Hegel subsequently phrased it "immanent" adaptations seen in living organisms) Kant regards as extremely precarious all these hints of a higher view of nature. Nature as a machine, governed by changeless causal law, is necessary to thought. Were no such machine recognized, the thread of consciousness would be cut and orderly experience impossible; we must all go mad.[2] But nature breathing of life, or of beauty, or, however faintly, of a God immanent in the whole process, and shaping it towards moral purposes—that is or may be no better than a subjective dream. It is doubly uncertain. It has inferior guarantees, as compared with our knowledge of the mechanism of nature. And, after all, not even our knowledge of the mechanism of nature is a knowledge of reality. Things as they truly are lie wholly beyond our poor human vision.

Kant's imperfect unification.

Kant then has broken away from intuitionalism by substituting *one system of necessity* for the many necessary truths or given experiences from which intuitionalism takes its start. But there are gaps in Kant's system—a gap between sensation and the sense-forms of time and space; a gap between sense-forms and thought; a gap between the lower but practicable processes of the Understanding and the higher but unrealizable ideas of Reason. And thus Kant's idealism is incomplete. On one side, the world we know by valid processes of thinking cannot, we are told, be the real world. Or, beginning from the other side; neither the reality which ideal thought reaches after, nor yet the reality which our conscience postulates, is the valid world of orderly thinking. The great critic of scepticism has diverged from idealism toward scepticism again, or has given his idealism a sceptical colour, mitigated—but only mitigated—by faith in the moral consciousness. If there arises a system of philosophy in which all truths are grasped in unity, and it is seen that the principles of things *must* be what they *are*, such a philosophy will give us in perfection the idealistic conception of reality and the idealistic guarantees of truth which Kant gave brokenly. The Absolute Idealism of G. W. F. Hegel was such a system.

Hegel.

It ranks, up to our own day, as the last of the great philosophies, and the boldest of all. Kant had fewer isolated points of departure than intuitionalists; yet gaps and isolation recurred in Kant, and helped to make him the father of modern agnosticism. In the later intuitionalism of Hamilton, recoiling from Hegel, the many subjective necessities of the intuitionalist scheme were made to breathe the new agnostic suggestions. We *necessarily* think as we do—but only because of our entangling faculties. It is a mental "impotence" that makes us believe in such a law as Cause and Effect. Kant had substituted one great necessity, sprung from an ideal source. Reason—under conditions of sensation—created the world of (valid) knowledge; Reason created the practical world of duty. But, having said this, Kant went on to repeat the sceptical suggestion. The whole coherent necessary world of his philosophy became "our world," *as we necessarily think it*, but not by any means of necessity the world *as it is*. Hegel brushes aside all these hesitations. His *Philosophy of Nature*—one of the least admired parts of his system—is the answer from his point of view to Kant's assertion that a "perceptive understanding" is for us impossible. Hegel offers a supposed proof that Time and Space, Matter, Nature, are ascertainable and definable

[1] Mansel's term for Kant's "practical." It must be carefully distinguished from Kant's "regulative," which refers to knowledge—regulative in contrast to *constitutive* of knowledge—not to practice.

[2] This is Kant's positive refutation of Hume's scepticism.

necessities in a reasonable universe. Rational system is the first and last word in this philosophy. The element of givenness, dominant in empiricism, and partially surviving through intuitionalism even into Kant, is sublimated in Hegel's thinking. Everything is to be exhibited, in outline or in essence, as the working of necessary truth. You need not wish anything in the universe to be other than it is; as well grumble at once that two and two do not make five![1] Hegel will allow no dualism of fact and principles. Nothing is bare fact. Philosophy will show you that everything *has to be* so and so. The effect of this point of view in regard to moral perceptions is that they represent an important relative truth, but that philosophy "passes" beyond them "into a higher region, where imputation of guilt is" absolutely "meaningless"[2]—*jenseits des Guten und Bösen.* More peculiarly his own is Hegel's great doctrine of contradiction, whereby opposing views of truth rank as stages in one progressive definition. We may explain this to ourselves as an extraordinarily vehement recoil from Kant's deification of formal logic with its principle of "analytic" tautology. As a result, Hegel's system undertakes to show candid minds that incompatible assertions not only may but must both be true.[3] Through this unexpected and obscure principle of "dialectic"[4] Hegel claimed to fulfil his programme of interpreting everything as manifest necessary truth of ideal relationship. It all *must be so* and *you see it must.*

The "Dialectic" method.

Hegel wrote extensively upon religion, especially in his *Philosophy of Religion.* Yet it remains doubtful whether he was a theist with large pantheistic elements—such as every speculative mind will be likely to incorporate in theism—or a pantheist rejecting theism altogether. We may regard his ambitious programme as the last logical development of idealism and indeed of philosophy itself. If perfect knowledge be possible for us, it must take the form of such a system as Hegel offers. If the world exists purely to be known, and if every other working of reason comes into consideration *qua* incomplete knowledge, Hegel is right with his sweeping intellectualism. Or at least he has rightly seen what are the assertions to aim at; it is difficult to accept the principle or method upon which his answer to the riddle proceeds, the dialectic method. Perhaps it was necessary for human thought to try how far it would carry out this programme. And yet perhaps full success was neither possible nor desirable. If such are our conclusions, we return to a possible basis for theism not very far removed from that of intuitionalism. Certainly history shows that theism has generally been associated with some reduced or limited form of philosophy, usually with the intuitionalist scheme. It is not the first runnings of the stream of religious thinking which have given the world its theistic philosophies. Theism is an afterthought—the reply to doubt—the attempted reflective justification of what announced itself at first as a prophetic certainty. But no more is theism the first runnings of the stream of philosophy. It is philosophy harnessed to a practical and religious interest. It is philosophy called into court to answer selected questions.

Ambiguities on religion.

Theism then has its most habitual affinities with intuitionalism, but may fall under any one of our philosophical or *quasi* philosophical types. We have distinguished three types or tendencies: empiricism, intuitionalism, idealism. They deal respectively with what is—partly with what is and partly with what must be—with what must be. They are based on facts—upon facts in the light of principles—upon principles purely and ultimately upon one principle. They claim probability—moral certainty—mathematical certainty. They incline to the Design Argument and Analogy—to the Cosmological argument (with other elements in a subordinate place) and proof by inference—to the Ontological argument. This last and boldest argument is a system of idealistic philosophy in a nutshell. When such a system is worked out in full detail, it essays or ought to essay a proof of the following points: (1) God or the Absolute necessarily exists; (2) He necessarily is what He is; (3) He or it necessarily manifests itself in the finite, (4) and necessarily manifests itself in just this finite which we know from experience. If philosophy is able to fill up that programme, it justifies itself; it raises all belief to necessary truth; and whether its teaching be theistic or pantheistic, pantheism or theism, whichever turns out victorious, must henceforth rank as a demonstrated certainty.

Again, these contrasted philosophies throw light upon the meaning of *a posteriori* and *a priori* in Kant and subsequent writers.[5] To empiricism, all is *a posteriori.* To intuitionalism, half is *a posteriori* and half *a priori.* To idealism, all is *a priori.* Not that *a posteriori* is denied, or that idealism even in Hegel tries to evolve reality out of the philosopher's inner consciousness. Mere given fact may be the starting-point; but it is sublimated. We see by degrees—in general outline or upon general principles[6]—that *what is* is no other than *what must be.*

"A posteriori" and "a priori."

There is another conception of necessity which has established itself in the history of science and philosophy. We may call it mechanical necessity. If this conception is regarded as full and absolute truth, it involves materialism. When we recollect the empiricist starting-point of science, it is curious to observe with what vehemence the average man of science now rejects free will. To him, it *cannot* be true. William James stood almost alone in being prepared to go anywhere at the bidding of apparent facts, unconcerned about rational probabilities. On this ground James is a libertarian. The fact appears to be so; he reports it. Similarly, James is willing to believe in many universes *nebeneinander* or *durcheinander* but not *ineinander.* Dualism, pluralism, manifold parallel inconsistency may belong to the nature of fact. Does our intelligence demand unity? That may be a mere subjective fancy. Even polytheism,[7] or something indistinguishable from it, is suggested to this doggedly empiricist mind by the *Varieties of Religious Experience;* they are all good to those to whom they appeal; and what right have we to talk of objective standards?[8] Ordinary "inductive" empiricism shows that it has travelled far from this unprejudiced credulity when it asserts its hard determinism—uniform law, never broken, never capable of being broken. But what is mechanical necessity, if we admit that in some sense it exists? It is a *relative* necessity. The present and the future have to be what the past and the absent make them. Past events, "happening" to be what they were, have fixed subsequent processes to their channels. But you can never, at any one point, say, from the scientific or mechanical or materialistic standpoint, this "had to be."[9] The relative necessity never passes into an absolute one. A different primitive "collocation," as T. Chalmers[10] put it, would have yielded, by the same process of natural law as ours, quite a different universe from ours.[11] T. H. Huxley admitted that this contention could not be ruled out as impossible. Again, in the scheme of mechanism, everything is determined by everything else—in

"Mechanical necessity."

[1] "It may be asked, Why can God not *create* a triangle whose three angles shall not be equal to two right angles? *To abstraction and ignorance everything is possible.*" From notes of a class lecture by Dr E. Caird.

[2] F. H. Bradley, *Ethical Studies*, p. 4.

[3] J. E. MacTaggart (*Studies in Hegelian Dialectic*) contends that direct contradiction is confined to the elementary portions of Hegel's *Logic*: but he does not deny its existence there, though his interpretation, could one accept it, softens the paradox.

[4] Used by Kant sceptically of the limitations of reason, dialectic in Hegel becomes constructive; and scepticism itself becomes a stage in knowledge.

[5] (1) Aristotle and the schoolmen meant by a proof *a priori* reasoning from cause to effect. (2) Kant is often supposed to mean by *a priori*—see Hamilton's *Reid*, p. 762—"innate" as opposed to "acquired from experience." (3) If we accept the suggestion offered above—that *a priori* in Kant and later thinkers = necessary—we place ourselves on the track which leads from intuitionalism to some form of idealism.

[6] Why only in such general terms? But this limitation is always taken for granted.

[7] It does not seem as if James's "Pragmatism" could lend itself to anything so concrete as a theistic conclusion.

[8] A very different thinker, Dr J. E. MacTaggart, works round from idealism to an eternal *quasi* polytheistic society of equal souls.

[9] H. Spencer's "instability of the homogeneous" is perhaps an attempt to perform the impossible (*First Principles*, chap. xix.).

[10] Quoted in J. S. Mill's *Logic*, and with fuller sympathy in W. S. Jevons's *Principles of Science.*

[11] God has ordered the original "collocation"—a new statement of the argument which traces Design in nature.

space as well as in time; nothing does anything for itself. Yet again, nature is broken up into co-operating parts; the whole is the sum of these parts; or, if you prefer to say so, there is no whole. But, if we should take the view that nature is infinitely extended—part of the "Antithesis" in Kant's first "Antinomy"—relative necessity breaks down on the last analysis, since boundless nature may overwhelm that sequence which we thought most securely established. Who can say what may emerge from an infinite background? We reach similar conclusions when we recognize that the laws of nature are general or hypothetical; not in Mill's sense ("If you *had* such a non-existent thing as three perfectly straight lines united in a triangle"), but in a sense noted in F. H. Bradley's *Logic:* "If" or "*As often as you have* the cause working unimpeded, you get the effect." Pure scientific theory cannot tell you when you have got such a cause, or whether you ever get it at all. No law of nature contains in itself a promise that it shall pass into operation. Its doing so depends upon the totality of conditions. Materialism supposes that this mechanical order is the real world and the only real world—mechanical monism.[1] Intuitionalism supposes that there are two realms—of necessity and freedom, of nature and will, of matter and mind; contiguous, independent, yet interacting—dualism. Idealism in one way or other supposes that mind is more real than matter. And thus its first programme—*All is in accordance with reason*—may pass into the more doubtful programme *All is reason*, in one of the two forms (*a*) nothing exists but mind (*e.g.* Hegel, as often interpreted—pantheistically?) or (*b*) *nothing exists but minds* (*e.g.* Hegel, as interpreted by Dr MacTaggart). Anyhow, whatever the method or interpretation is to be, idealism, even more fully than materialism, is pledged to monism and to the rejection of dualism. The valid or scientific but metaphysically untrustworthy knowledge, to which Kant shut us up, was knowledge of a mechanical universe. His reply to

Kant's reply to Hume.

Hume was this—Mechanical causation is as real as the unity of consciousness. It is false to suggest that sequence is a fact and causal connexion a figment; apart from causal connexion, there could be no consciousness of sequences. Over against this "valid" mechanism, in some truer but vaguer region, Kant placed free will; and so left things. The English thinkers influenced by Hegel are inclined to assert mechanism unconditionally, as the very expression of reason—the only thinkable form of order. Thus libertarian free will has to disappear from their belief. In this interpretation of the universe, the difference between mechanical or relative necessity and absolute or ideal necessity is slurred, or dogmatically affirmed to be non-existent. It might be suggested in reply that free will, whether or not it be ultimate truth, is true to the same degree of analysis as mechanical necessity itself. Mechanism is that which obeys impulses from outside. It is profoundly unsatisfactory to regard mechanism as the whole ultimate truth. For such a rôle it is in no sense fitted. If it is ultimate truth in its own region, that region cannot be accepted as more than half the entire universe of reality (common sense intuitionalism; dualism). If mechanical determination applies to the whole universe, it cannot be ultimate truth at all (cf. H. Lotze; more drastic in Ward's *Naturalism and Agnosticism*).

Quite a different view of necessity is the *moral* necessity pointed to by Kant's "Practical Reason." And, as the sym-

Moral necessity; Kant.

pathizers with Hegel try to force mechanical necessity into the garb of absolute or ideal necessity, so they seek to show that moral necessity is only an inferior form of absolute or ideal or, we might say, mathematical necessity. Theists, on the other hand, will contend that the distinctiveness of moral necessity is vital to religion. Thus we might restate our grouping of philosophies in terms of the views they take regarding necessity. Theism is directly interested in this, since it affirms the *necessity* of God's existence. At least, it would be hard to name any school of theists which was content to affirm that there "happened" to be a God.[2] On the other hand, theism does not desire to see necessity—or Fate—ranked as superior to the living God.

Evolution.

One great change and only one since Kant's day has affected the outlook upon theistic problems—the increasing belief in evolution. It is a manifest weakness in intuitionalism that it finds such difficulty in leaving room for evolutionary change. All men may perhaps be aiming everywhere at the same moral ideal,[3] but it is absurd to say that all men actually formulate the same moral judgments. On the other hand, many evolutionists ignore the certainty that there must be a *continuum* in any real evolutionary process. In the light of that truth, a reformed intuitionalism might justify itself. But fuller conceptions of evolution raise further difficulties for intuitionalism in its wonted forms. Knowledge cannot be divided into the two components—immediate certainties, precarious inferences. The starting-point is reconsidered, modified, transformed, in the light of subsequent acquisitions. Knowledge grows, not by mechanical addition, but by organic transformation. This may help us to appreciate the meaning of Hegel's Dialectic. His thought then is not wholly paradox, whatever the expression may be. Hegel's system is, in its own way, a great evolutionary philosophy of an ideal type.[4] Evolution, repelled by the older intuitionalism, was thus incorporated in the greatest of all idealisms. It has also been largely applied to empiricism. Sometimes one questions whether empiricism is really still empiricist; so much of the *a priori* has come in under the name of evolution (*e.g.* in Herbert Spencer). But the change, if it has taken place, is unrecognized.

Outline history of theism. Socrates.

IV. Greek philosophy for our purpose begins with Socrates, who formulated the Design Argument. His ethics have sometimes been regarded as pure utilitarianism (so *e.g.* H. Schultz); but it is surely significant that the great idealism of Plato was developed from his suggestions. The new method of definition which Socrates applied to problems of human conduct was extended by Plato to the whole universe of the knowable. In the light of this, it may be possible (with J. R. Seeley in *Ecce Homo*) to call Socrates the "creator of science." The man who inspired Plato deserves that name. Those Ideas according

Plato.

to which all reality is objectively shaped—and therefore too, as a modern would add, subjectively construed—include the idea of the Good, which Plato identifies with God. We might mislead ourselves if we interpreted this expression as referring to moral goodness; on the other hand, Plato more than most of the Greeks thinks of moral virtue as an imitation of God. With all its idealism, Greek thought had difficulty in regarding rational necessity as absolute master of the physical world. Matter was a potentially recalcitrant element. Hence there are tendencies even in Plato to build up the ideal world in sharp contrast to the actual world—to the half interpenetrated or half tamed world of matter. His suggestions as to immortality are affected by this. The body is the soul's prison. He teaches (whether suggestively, metaphorically or deliberately), pre-existence[5] as well as survival; perhaps he is moved to this by non-Greek influences. Thus at several points Plato reveals germs of dualism and asceticism. Free will had not yet been formulated as a problem. Aristotle has impressed the ordinary mind chiefly by his criticism of Plato's

Aristotle.

ideal theory; and therefore he is often ranked as the father of *empiricists*. But those who treat him as the great

[1] Ernst Haeckel will not allow us to call his system "Materialism," because he affirms that the rudiments of matter are also rudimentary "mind stuff" (to use W. K. Clifford's term). But in spite of this its materialistic affinities are unmistakable.

[2] Still, Lotze's criticism of the cosmological argument reveals his realist side. On the other hand, in discussing the ontological argument, Lotze commits himself to a moral *a priori* (below, *ad fin.*).

[3] "We are all embarked upon a troublesome world, the children of one Father, *striving in many essential points to do and to become the same*" (R. L. Stevenson).

[4] The idea of evolution *in time* (physical evolution) was laughed at by Hegel.

[5] A belief hinted again at the close of Lessing's *Education of the Human Race*; also—more definitely—by J. E. MacTaggart (*Studies in Hegelian Cosmology*, p. 48; and elsewhere).

Realist make him almost if not quite *intuitionalist*; while there is also an *idealist* reading possible. The threatened dualism of ideal and material becomes for Aristotle mainly a contrast of matter and form; the lower stage in development desires or aims at the higher, matter more and more tending to pass into form, till God is form without any matter. But this God of Aristotle's is a cold consciousness, imitated only by the contemplative virtue of the philosopher, not by the morally active citizen. And the chief contribution of Aristotle to theism is a theory, found in his *Physics* as well as his *Metaphysics*, of God as first mover of the universe, himself unmoved. This theory is generally ranked as the earliest appearance in European thought of the cosmological argument. Free will is shaping itself towards discussion in Aristotle's *Ethics*, but is hardly yet a formulated problem. For anything like personal immortality the medieval Schoolmen searched him anxiously but in vain.

Epicureanism need not detain us. It is a system of empiricism and materialism, remarkable only for teaching free will. Atoms swerved as they fell endlessly downwards, and thus introduced an indeterminate or irrational element into the processes of the world. Theism can take but little interest in this peculiar type of free will doctrine, or again in Epicurus's professed admission of the existence of gods—made of atoms: inhabiting the spaces between the worlds; careless of men. **Stoicism.** Stoicism is a much more important system, but harder to classify. Perhaps in the department of thought where it is most in earnest—in ethics—it is an idealism. It tells men to "obey reason" and crush passion, or to live "according to nature." In physics—but in that region of speculation its positions are more perfunctory—it teaches pantheism on a *quasi*-materialistic basis. God is the soul of the world, although the gods of popular belief are (at least by the later Stoics) respectfully if exoterically acknowledged. Human survival is taught, but not ultimate immortality; and, as against Epicureanism, Stoicism on the whole tends to deny free will. There is perhaps a certain religious enthusiasm in the thought of being passively determined by Fate, the Universe, Zeus. Finally, the Stoic analysis of the process of knowledge is sensationalist and empiricist.

So far as a coherent body of theistic doctrine exists, it did not grow out of the great systems, but out of the lesser men who stood nearer to the apprehension of practical citizens. Perhaps the most important of these popular thinkers was Marcus Tullius Cicero—no great philosopher, but a graceful and effective man of letters. **Cicero.** It has been truly observed[1] that the lineaments of intuitionalism are very clear in him. He also gives us "natural law"[2]—a Stoic inheritance, preserving the form of an idealist appeal to systematic requirements of reason, while *practically* limiting its assumptions to those of intuitionalism. Formally, Cicero adhered to the Academic[3] philosophy during its "middle" or almost sceptical period. (The senses are so far from truth that we must be content with reaching probability.) In Cicero's *De Natura Deorum* the burden of theism rests mainly on the Stoic interlocutor. The conclusion, "academically" recognizing the contendings of one disputant as more "probable," is imitated in D. Hume's *Dialogues Concerning Natural Religion*. In the great Roman Stoics—Seneca, Epictetus; less material for theism perhaps in Marcus Aurelius—**Seneca.** we see the partial softening and religious deepening of the system, and a doctrine of the wise man's power over passion and circumstance which has all the essentials of Libertarianism. Philo of Alexandria should also be mentioned. **Philo.** He blends the tradition of the Old Testament with Greek philosophy, and, within the latter, exhibits that union of Platonism with Stoicism, especially in the doctrine of the Logos, which became dominant in the Christian apologists and the great theologians of the ancient church. Philo is Greek enough to believe in the eternity of matter; otherwise he preserves the main outlines of Old Testament theism. He teaches free will and immortality; and the design and cosmological arguments are both traceable in him. Augustine of Hippo transmits a type of Platonism as part of his legacy to the **St Augustine.** Western church. Against Manichaean dualism he had vindicated free will; but as against Pelagianism he taught the bondage of sinful man—a position accepted in the East but never welcome there, and not more than half welcome even in the West. From this theological entanglement the problem of free will did not escape for long centuries. In spite of some waverings towards what has lately been called "conditional immortality" (see APOLOGETICS) the doctrine of "natural immortality" championed by Augustine became dominant in the church; an instalment of what was afterwards to be called Natural Theology; and a postulate or presupposition to-day—like free will—in Roman Catholic apologetics.

[2] See above (*ad init.*).
[3] Platonic.

The middle ages, in the person of Anselm of Canterbury, contribute the first clear form of the Ontological argument for theism. If our grouping of philosophies, as given above, is sound, **Middle ages.** every idealist scheme contains potentially an ontological argument. In other words; whenever philosophy teaches a doctrine of the Absolute, and regards such doctrine as valid and certain, we have the essence of an ontological or *a priori* argument. Of course it remains debatable whether this philosophical Absolute is necessarily interpreted as a personal God, or perhaps even whether logically it can be. But the Christian bias is sure to make theologians, who borrow a doctrine of the Absolute, interpret it in a Christian sense; hence we may consider it something of an accident that even an Augustine fails exactly to put the argument in form. Anselm tells us that a most perfect being must exist, since the perfection which includes existence is manifestly greater than a perfection confined to an object of thought. Some of the impression of paradox here is due to Anselm's treating the Absolute simply as one among many other beings, and to his treating existence simply as one element in the quantitative sum of perfections. At least, idealist philosophy will hold that the substance if not the form of the argument is sound[4] though the question of its interpretation remains. In Anselm's case we have the further sanguine hope of justifying not theism merely but all Christian doctrine to the scientific reason. Thomas Aquinas, following Albertus Magnus, but with greater power and greater influence, occupies substantially intuitionalist ground. He will not have the Ontological argument; but he asserts Natural Law, and relies upon the cosmological and design arguments—with various refinements and distinctions, differently stated in his two *Summae*. In declaring the supreme doctrines of Christianity to be mysteries above reason, he marks off a lower region where reason is to reign; the study of that lower region may well be called, as later centuries have called it, Natural Theology; and as such it presents strong intuitionalist affinities. The critics of Aquinas—Duns Scotus and the later Nominalists—show some tendency towards rational scepticism. They exercise their acumen in multiplying difficulties; but all such questionable doctrines are presently re-established from a different point of view as truths of faith or findings of church authority. The Church of Rome has discouraged these daring tactics in favour of the more cautious and probably more defensible positions of Aquinas. In Raymond of Sabunde's form of moral argument—there must be a God to reward and punish, if human life is not to be "vain"—we see the kinship of that argument to the argument from design.

René Descartes, a faithful though not an unsuspected Roman Catholic, founded modern philosophy by his starting-point of universal doubt and by his arguments in **Descartes.** reply. One may regard him as an idealist, though Scottish intuitionalism—especially in the writings of Professor John Veitch—has claimed him for its own; and indeed Descartes's two substances of active mind and passive extended matter are very much akin to "Natural Dualism." Still, Descartes has marked idealist traits, as when he refurbishes the ontological argument with clearer emphasis on the perfect being as "necessarily" existent[5]—reasoning a shade less quantitative or a shade more subtle than Anselm's. Descartes's preliminary statement of the argument in somewhat popular form brings it very near the lines of the cosmological proof.[6] There must be a *cause* for nature, but particularly for the idea of perfection in us—that cause must be God. The radical side of Descartes appears again in his offering his own type of theism as a substitute for the old proofs—not a supplement. Design especially was under suspicion with him. He was even more definitely opposed to "final causes" than Francis Bacon, who excluded them from science but admitted them to theology. All this was connected with zeal for physical and mathematical science. Descartes was an expert; Bacon was the prophet of a great, if half comprehended, future; and the science they loved was struggling for its infant life against a mass of traditional prejudices, which sought to foreclose every question by confident assertions about the purposes of God and Nature. A difficult question arose for Descartes's philosophy, when it had to explain the union in man of the absolutely opposite substances,

[4] Cf. J. E. MacTaggart in regard to Hegel, *Studies in Hegelian Cosmology*, chap. iii.
[5] So *Meditation* 5, at least in the French version. Again: "Existence cannot be separated from the essence of God"; compare Spinoza's ethics, definition 1; "By *causa sui* I understand that the essence of which involves existence, or that which by its own nature can only be conceived as existing."
[6] *Meditation* 3.

mind and matter. Malebranche gave all causation to God; and the acosmist—as Hegel called him, in repudiation of Bayle's nickname "atheist"—Spinoza, from the premises of Cartesianism, and from other suggestions of the past, developed that great system of determinist pantheism which was a scandal and a terror to his generation. Really, he urged, there could be only one substance—Descartes himself had dropped a passing hint to that effect—and the bold deductive reasoning of Spinoza's *Ethics*, in process if not in result, betrays its kinship to the ontological argument, with its affirmation of what *must be*. Thought and extension are peaceable attributes in this one substance; there are infinitely many other attributes, but these only are known to us.

Spinoza.

In a different region, the tradition of Descartes passes on to G. W. Leibnitz. He accepts the ontological argument with a qualification—almost like his disciple Wolff, who tries to use it for *defining* the divine *attributes*. Leibnitz's Monadology—which has little influence on his theism—may be viewed as a strong recoil from Spinoza's all-swallowing substance. The more Spinozistic side of Leibnitz's thought—God as Monad of Monads—is a theistic postulate if hardly a theistic proof. The free will which Leibnitz teaches is not libertarian but determinist. Each monad works out necessary results, but these flow from its own nature; and so in a sense it is free. Reciprocal action is explained away into a "pre-established harmony" between every monad and all others. In his *Theodicy* Leibnitz argues, like not a few predecessors, that this universe must be regarded as the best of all *possible* universes. Pain and sin *must have been* reduced to a minimum by God; though they are so ingrained in the finite that we have to make up our minds even to the endless sin and endless punishments of hell. It has been truly said that such optimism is a profound relative pessimism. The best? Yes, perhaps the best *possible*; in familiar speech, the best of a very bad business. But why must universes be so bad? Leibnitz's philosophy has no answer for us. In another direction, Leibnitz—and Wolff—give emphasis to the contrast between the *necessary* and *the contingent*; with important results for popular philosophy, and indirectly for theism. The disciple, Christian Wolff, is one of the most typical figures in the history of theistic thought. He is a pure scholastic. The great thoughts of his master—or perhaps indeed rather Leibnitz's secondary thoughts—are dried and pressed by him, labelled and catalogued. Monadology drops out of Wolff's teaching. Pre-established harmony drops out—except that it is used to explain the union of soul and body. Wolff tells us that six Latin works contain his system:—*Ontology*, *General Cosmology*, *Empirical Psychology*, *Rational Psychology*, *Natural Theology*, i.; *Natural Theology*, ii. In the volume on *Empirical Psychology*, Wolff discusses free will. He decides that human actions are caused or determined by the nature of the agent, but that, as man is not a necessary being, his actions are contingent. This view seems to preserve all that is questionable in Libertarianism, while omitting its moral meaning. The *Rational Psychology* formulates immortality on the ground that the immaterial soul has no parts to suffer decay— the argument which Kant's *Critique of Pure Reason* "refutes" with special reference to the statement of it by Moses Mendelssohn. The earlier of the two volumes on *Natural Theology* relies on the cosmological argument; the later—obviously an afterthought—tries to vindicate the ontological argument as an alternative basis for theism, but awkwardly and with manifest uneasiness. In the end, this volume diverges into the *Attributes*, construing God in the likeness of man *via eminentiae*.[1] No writer can be less intrinsically worthy of study than Wolff. But he is immortal as the man against whom Kant directed his tremendous battery;[2] and he is also tolerably characteristic in outlook. He is no intuitionalist; but he is a drily common-sense mind, piling up in heaps the ruinous fragments of an idealist system.

Leibnitz.

Wolff.

[1] Human attributes magnified, or their weak points thought away. The Schoolmen sought to establish other divine attributes by *negation* of human weaknesses and by finding in God the *cause* of the varied phenomena of creation.

[2] On one side; another battery of Kant's was aimed against Hume.

In England, empiricist thought found a prophet in Bacon. He draws no inferences to theology or religion, whether friendly or hostile, from his new positions. He takes the line of separating the things of God from those of Caesar, and defends the traditional Protestant theology with obvious sincerity. Thomas Hobbes, a rough and anomalous but vigorous thinker, is the fountainhead of a more formidable empiricism. He is almost a materialist. In ethics, he is a hard determinist and hedonist, though not without qualifications (man's boundless desire for "gain and glory") and peculiarities. He saves himself theologically by affirming that the good citizen will be of the same faith as the government —which had best be a monarchy. In that sense, living under a professedly Christian ruler, Hobbes himself is a Christian. John Locke, the real father of English philosophy, took the field against what he regarded as Descartes's impossible programme of "Innate Ideas."[3] But Locke is a double-minded or half-hearted philosopher. He admits two sources of knowledge—sensation and *reflexion*; and God is to him the Great First Cause, especially of our own existence (or of the existence of *finite minds*). This is a form of the cosmological argument, and ought to go with an intuitionalist not an empiricist doctrine of causality. On ethics, Locke says very little, although that little is hedonist and determinist. But once again in his political writings he breaks away from empiricism in appealing to *natural law*—an intuitionalist or conceivably an idealist tradition. Locke is thus a sensationalist and empiricist, but incompletely, and without perfect coherence. His suggestions led to different developments. In France, through Condillac, the inconsistencies were purged out, and materialism was ready for the next comer to affirm—though it may be said with R. Flint that while materialism requires sensationalist psychology, yet the psychology in question allows no valid inference to matter, and therefore destroys materialism. Bishop George Berkeley, afraid of materialistic developments from a philosophy he was not prepared fully to recast, took refuge in immaterialism. Locke had treated ideas as testifying to the existence of matter. But can they? The inference seemed unwarrantable. Why should not God, a spirit like our own, though greater, speak to us in this language? In *Alciphron or the Minute Philosopher* Berkeley gives the fullest statement of this argument, while adding more commonplace attacks on the *pettiness* of religious scepticism. David Hume, following up Berkeley's leading suggestion, pointed out that the inference to God is as precarious as the inference to matter, and that the assertion of a continuous or immaterial mind in man also goes beyond the immediate facts. The truth is, that all truth is uncertain! Scepticism, with which P. Bayle had played as a historian—he amused himself, too, with praising the Manichaean solution of the riddle of the universe—became a serious power in the history of philosophy with the advent of David Hume. Still, it may be doubted how far Hume was in earnest. Nay, it may be questioned how far it is either psychologically or logically possible to turn general scepticism into a coherent doctrine. The *Dialogues Concerning Natural Religion* constitute Hume's formal profession of religious faith. The existence of God was no doubt probable; but what a number of difficulties there were! Still, one would not dispute whether God existed; but what he was—that was the hard question. This treatise must not be confused with the *Natural History of Religion*, in which Hume acts as a pioneer for comparative religion, with its study of facts. Even in that book Hume is able to play with sceptical solutions. Religion began in fear—as if it were no more than a lying superstition. Of course once more Hume saves himself by strong professions of admiration for rational or natural religion. It was not yet socially safe to be a confessed religious sceptic.

Hume.

[3] And against similar views in Lord Herbert of Cherbury.

Samuel Clarke, who defended Newton's view of the world against Leibnitz's strictures, is perhaps chiefly interesting to us as one of the authorities of Bishop Joseph Butler. It is Clarke's defence of free will, Clarke's idealist theory of eternal "fitness" as the basis of ethical distinctions, perhaps Clarke's teaching on immortality, that Butler regards as "the common known arguments" and authoritative enunciations of truth in the regions of philosophy or Natural Theology.[1] Butler himself occupies a peculiar position in more respects than one. He has profoundly influenced British thinking, but is little known abroad. He is difficult to classify. We may be helped in assigning him his proper place if we observe that, almost invariably, he accepts certain beliefs which he forbears to press. Thus in his most important contribution to ethics, the *Three Sermons on Human Nature*—i., ii., iii. of the *Sermons*—he grants the validity of an appeal to "nature" upon the lines of a sort of Stoical idealism, but for his own part he prefers the humbler appeal to *human* nature. He makes the issue, as far as possible, a question of fact. We, from the altered modern point of view, may doubt whether Butler's curious account of the mechanism of moral psychology *is* a simple report of facts. There are (*a*) given instinctive "propensions"; (*b*) a part of higher principles, "benevolence" and "rational self-love," equally valid with each other, though at times they may seem to conflict; (*c*) there is the master principle of conscience, which judges between motives, but does not itself constitute a motive to action. Butler is opposing the *psychological hedonism*[2] of Hobbes. He does not find it true to experience that man necessarily acts at the dictation of selfish motives. But Butler—for reasons satisfactory to himself, and eminently characteristic of the man; he hoped to conciliate his age!—dwells so much upon the rewards of goodness, as bribes (we must almost say) to rational self-love, that some have called Butler himself an *ethical hedonist*; though his sermon on the "Love of God" ought surely to free him from that charge. In all this, Butler was convinced that he was giving a simple statement of facts. Any one introspectively apprehending the facts must grant, he thought, that benevolence was an integral part of human nature and that conscience was rightfully supreme. This reveals the empiricist temper, and points to an attempted empiricist solution of great problems. Butler holds that more ambitious philosophies are valid, but he shrinks from their use. The same thing is seen again in the *Analogy*. Butler divests himself in this book of the principles of "liberty" and "moral fitness" in which personally he believes.[3]

Butler.

Part i. of this book shows the "Analogy" of "Natural Religion" to the "Constitution and Course of Nature." Probably "Nature" is here employed in a more familiar or humbler sense than in the passing reference in the *Sermons*. The *Analogy* means by "nature," indisputable human experience. Deists believed in a God of unmixed benevolence; Butler's contention is that justice, punishment, hell-fire itself are credible in their similarity to the known experiences of man's life upon earth. What the *Three Sermons* sought to find written small within—a law of inflexible justice or righteousness—part i. of the *Analogy* seeks to discover written in larger characters without us. Butler is charged by Sir Leslie Stephen with arguing illegitimately—professing to make no appeal to "moral fitness," and yet contending that the facts of human life show (the beginnings of) *moral* retribution for good and evil. Assuredly Butler did not mean to give him his right of speaking about moral evil and good when he waived the "high priori" method of vindicating their real existence. Yet it is a very grave question whether the idea of God's moral government admits of being argued as pure matter of fact. Butler tries to do this. You call it unjust, he says in effect, that you should be punished. You argue, for example, that you have no free will. Well, what of that? Does it not look very much as though you *were* being punished? Does not nature seem to treat you *as if* you had free will?[4] One thing more should be noted about Butler. He nowhere formally argues for the truth of theism. He will not waste time upon triflers who deny what he thinks, in the light of the (empiricist!) Design argument, an absolutely clear truth.[5] On the whole then Butler in personal conviction is an intuitionalist, wavering towards the idealism of his age; but in argument he is an empiricist, trying to reason every question as one of given facts. None the less, in the issue, it is the very element which goes beyond an appeal to facts—it is the depth and purity of Butler's moral nature—which fascinates the reader, and wins praise from Matthew Arnold or Goldwin Smith or even Leslie Stephen. Precisely because he goes beyond phenomenal sequences, it is impossible to fling him aside unheard. On the other hand, no Christian, and perhaps no theist, is interested in maintaining that Butler grasps the whole truth. At the most we might say this: If theism is a growing doctrine, Butler in England like Kant in Germany stands for a fresh ethical emphasis.

Stephen accuses Butler of reasoning in a circle. The things which make for our ultimate welfare are the things we call morally good. No wonder if they prove to involve happiness; that is their definition! But is it? Does not Stephen himself rather say that morally good things are conditions of *social*, not personal welfare? Butler's argument is that the individual suffers (and feels that he suffers deservedly) from neglecting these. If George Eliot is guilty of a platitude when she says that "consequences are unpitying," then Butler's argument is empty: but not otherwise.

Butler on the soul may be studied in chap. i. of the *Analogy*—where we observe the old assumption of an immaterial and so immortal principle—and in his appendix on *Personal Identity*. Wherever moral postulates make their presence felt, Butler's doctrine of man, as of God, leaps into new vigour.

It is a moot point whether S. Clarke's *Demonstration of the Being and Attributes of God* is really *a priori*. Clarke appeals to the immensity of time and space as involving infinity in God. A modification of his views is the starting-point of W H Gillespie's able *Argument a priori for the Being and Attributes of the Godhead*, published part by part 1833–1872. We find something curiously similar in James Martineau's *Study of Religion* ("Implicit Attributes of God as Cause," *sub fin.*). One might also compare J. R. Seeley's *Natural Religion*—though he is no decided champion of a personal God—and F. Max Müller's *Gifford Lectures*. Dismissing his earlier intuitionalism, in order, like Butler, to conciliate an empiricist age, M. Müller tried to show that even sense experience throws us on the Infinite—which for him was the kernel of the idea of God. He therefore appealed to the Indian goddess Aditi or Immensity, a deity connected with a set of personal gods called Adityas. Looking into the immensity of space, man also looks into the depths of godhead. Whatever one may think of the cogency of such arguments, it seems safe to conclude that thinkers, who dislike constructive idealism, but accept time and space as boundless given quanta, reach in that way the thought of infinity, and if they are theists, necessarily connect their theism with reflexions on the nature of Time and Space.

We have already spoken of Kant's peculiar philosophical positions. One result of these is a very damaging attack upon traditional theism. Kant puts together, as belonging to "Rational Theology," three arguments—he is fond of triads, though they have not the significance for him which they came to have for Hegel. Then he attacks the arguments, one after another. Is there anything fresh in the attack? Or is it simply a reiteration of his sceptical contrast between phenomena and noumena, and of his confinement of (valid) knowledge to the former? Perhaps the attack on *cause* as used in the cosmological argument is independent of Kant's philosophical peculiarities. The argument affirms a first cause, or uncaused cause. Does it not then deny rather than assert universal causation? But that special criticism is a question of detail. A more entirely novel and more general principle of Kant's attack upon theism is the challenge of our right to build up the idea of God bit by bit out of different arguments. The arguments had been regarded as alternative or else as cumulative proofs, all pointing to one conclusion—God exists. Kant insists that they are incompatible with each

Kant as critic of theism.

[1] *Analogy*, part i. chap. i. ("the natural and moral proofs of a future life commonly insisted upon"); last sentence of part i., *Conclusion* ("the proper proofs of [natural] religion from our moral nature," &c.); part ii. chap. viii. *sub fin.*, "the proof" of religion, "arising out of the two . . . principles of liberty and moral fitness."

[2] These useful distinctions are stated and well explained in W. R. Sorley's *Ethics of Naturalism*.

[3] *Analogy*, iii. chap. viii.; following S. Clarke?

[4] Part ii. of the *Analogy* tries similarly to establish Christianity as credible matter of fact, sufficiently analogous to known facts of experience (APOLOGETICS) apart from any moral "value judgments" (as Ritschlians might say).

[5] See (*e.g.*) ii. chap. ix. The *Three Sermons* also point to a *moral* argument for theism, but forbear to press it (Sermon ii.; when the *third* sense of the word "Nature" is being explained).

other. They offer alternative and mutually exclusive conceptions of God. If the God of the cosmological argument is the "Great First Cause," we have no right to identify him with the "Most real being" of the Ontological argument. If the God of the Design argument seems a limited being, working as an artist upon given materials,[1] he is hardly God at all. Kant takes for granted that we cannot sum up these imperfect conceptions in a wider reconciling truth. It is a shrewd criticism, but needs arguing out. A great deal of popular theism is undoubtedly hard hit by it; for popular theism is apt to throw its arguments together in very random fashion.

It is no more than characteristic of Kant's whole speculative philosophy that he should think the Ontological argument the one which comes nearest to success (yet the Ontological argument is held to prove—or rather to point out—not that God must exist, but that we think of him as necessary if we think of him as existing at all). As a result of this, Kant is metaphysically a sort of pantheist. The God whom all our thinking feels after is the all-inclusive system of reality. On the other hand, Kant's religion is of a type which requires a sort of deistic God, standing outside the world and constraining it into moral paths, or standing outside our moral struggles and rewarding our goodness. Butler fears profoundly that there must be a just God who will punish us. Kant hopes, with tolerable strength of conviction, that there may be a just God who will reward us.

Hegel on theistic arguments.

The main line in pure philosophy runs on from Kant's wavering and sceptical idealism to the all-including gnosis of Hegel.[2] Hegel inherits from Kant the three arguments, and takes them as stages in one developing process of thought. The cosmological argument points to nature-pantheism, with the religions—especially those of India—which embody that attitude of mind. This involves a re-interpretation of the Cosmological argument, or a criticism of the view ordinarily taken of it. Trace out the clue of causation to the end, says Hegel in effect, and it introduces you, not to a single first cause beyond nature, but to the totality of natural process—a substance, as it were, in which all causes inhere. This is a suggestion which deserves to be well weighed. The Design argument is held to give a contrasted view. It suggests in every deed a personal but limited God, or a number of Gods—"Religions of spiritual Individuality," including, along with "Judaism," the anthropomorphic religions of Greece and Rome. Finally the Ontological argument sums up the truth in the two previous arguments, and gives it worthier utterance in its vision of the philosophical Absolute. This is the last word of religious truth, though pure philosophy stands still higher. And, in some sense not clearly explained, Hegel identifies this final religion with Christianity.

Theism after Kant.

The theism of Hegel is ambiguous.[3] Later theists may be grouped according as their thought has been remoulded or not by the influences of Kant. The distinguished writers, whom we have to regard as repeating in essence pre-Kantian theories, generally know Kant, and frequently show traces of him in detail. But it is a plain finding of history that he has brought no "Copernican revolution"[4] to their minds.

Paley.

Empiricism is restated by Paley, who is Kant's younger contemporary as a man and also on the whole as a writer. Doubtless the archdeacon knew nothing of the German professor, and would have cared nothing for him however well he had known him. A much more significant figure is that of J. S. Mill in the tentative approach to theism found in his posthumous volume (*Three Essays on Religion*; 1874).

[1] The Design argument has mainly to do with living bodies. Might one suggest that organisms *seem* at least to be a working up of inorganic matter for new ends, viz. those of life?

[2] The idealisms of Fichte and Schelling made contributions to Hegel's thought; Krause and the Roman Catholic Baader represent parallel if minor phases of idealism.

[3] Equally so the Hegelian attitude towards personal immortality.

[4] Such as Kant claimed to effect: *Critique of Pure Reason*, preface to 2nd ed.

J. S. Mill.

Mill directs his attention to the Design argument. The inference that organized bodies are due to an intelligent cause is only reached by the "Method of Agreement"—a full inductive proof requiring, according to Mill's *Logic*, the "Method of Difference." Still, the Design argument is a good sample of a proof by means of the inferior method. Although nothing more than probability is established, it is a high probability.[5] Unfortunately, however, the method of agreement is liable to be baffled by "plurality of causes." In this instance it may happen that the work of intelligence has only been mimicked in nature by blind forces which have accidentally produced organic life; and Mill is disposed to hold that if the evolution of species should be clearly established as due to natural law—if there has been no creation by special interposition—the argument falls to the ground and theism (apparently) is lost.[6] A further point is of some interest. If Mill's theism holds, what is it? The belief in a God of limited power. That is what Kant contended that the Design argument pointed to, and Mill, proceeding on the Design argument, claims nothing more for his conclusion. Of course that was not Mill's special or conscious motive for denying divine omnipotence. His extreme sensitiveness and hatred of pain constrained Mill to hold that, if a good God exists, he cannot possess infinite power. Yet the correspondence between Mill's conclusion and what Kant had alleged to be implied in the underlying metaphysical position is very striking indeed.

Intuitionalism repeated; Flint.

Intuitionalism also has its restatements of theistic reasoning little modified by Kant. R. Flint's theism carefully excludes the early random talk (*e.g.* Cicero) of an intuitive or innate knowledge of *God*. What is self-evident, Flint justly remarks, neither needs nor admits of argument. We have intuitions of *cause*, of *infinity*, of *good and evil*. The Cosmological argument proves, with the help of the first-named intuition, that there is one great First Cause; and the Design argument shows the First Cause to be intelligent or personal. The Ontological argument, though not wholly rejected as a proof, is taken rather as pointing to God's attribute of infinity; thought rather than experience making affirmation that the intuition in question must be attached to God. The moral argument, relying upon the third intuition named, certifies us of a good God. In this way, the attributes are suggestively allotted among the four traditional proofs;[7] but we miss an explicit rebutting of Kant's hostile assumption, that it is incompetent for us to take the thought of God piecemeal.

Martineau.

Martineau's *Study of Religion* is also essentially intuitionalist. It has two parts: "God as cause" and "God as perfection." The Design argument comes in as a special illustration or intensification of the former of these, *i.e.* of the cosmological proof; but Martineau follows a side modification of intuitionalism (Maine de Biran, &c.) in identifying cause with will. This involves a very high doctrine of Libertarianism. The only ultimate cause is God. Nature exists over against Him; but its forces or processes are His own power in immediate exercise, except in so far as God has delegated freedom to human wills; and there follows a theodicy, repeating Leibnitz in more modern form. Martineau's two main proofs yield two sets of attributes; those known as "natural" and "moral," R. Browning's "power" and "love." In "God as perfection" Martineau handles the basis of ethics without reference to his own modification of the intuitionalist position (*Types of Ethical Theory*), according to which "good" is the better or the best. We may infer that, whatever the merits of that modification, it does not affect the theistic problem. Martineau's *Study* also includes a section upon Immortality. The Ontological argument is omitted; but we have already observed that there is a discussion of divine

[5] Paul Janet's *Final Causes* seems to follow Mill in this ("the fact of Finality"), but without naming him.

[6] Janet naturally is in opposition here. Ultimately, he argues, if not immediately, there must be a rational cause to account for so rational an effect. But again of course Mill is not named.

[7] The three which Kant criticized, with the addition of the moral argument, which he favoured.

infinity in relation to time and space which from one point of view is parallel to the Ontological argument.

Definite theistic idealism; Lotze.

Definite theism, bearing the mark of Kant's thought throughout, is found in Hermann Lotze. From the point of view of our grouping, he is an idealist of anomalous type. He begins as an empiricist or realist, with given matter-of-fact; but from time to time (*e.g.* in his *Microcosmus*) he makes readjustments without perhaps very clearly informing the reader what is being done, and in the end he is unmistakably idealist. While a pronounced theist—though not a church Christian—he is hardly less an assailant of traditional theism than Kant (*e.g.* his Outline [Lecture headings] on *Philosophy of Religion*). He dissents as a realist from the Cosmological argument in the form[1] in which it concludes from "contingent" to "necessary" being. We do not wish to find our way to a being who "must be." That is an idle dream. We must keep to real and assured facts. Lotze was a man of considerable attainments in special science; perhaps he reveals here the bias of the scientific mind, and possibly even its limitations. He regards the Ontological argument strictly so called as having been exploded by Kant. Still it has a value for him if taken not as an argument, but rather as the expression of an immediate conviction; viz. The highest must exist. This is an intuitionalist touch, or a parallel to intuitionalism, and has called forth a gibe from that very confident ratiocinator, J. E. MacTaggart; Lotze's immediate convictions are matter of interest to a biographer but to no one else. The Design argument elicits from Lotze the criticism that some things look purposeful, but others decidedly purposeless. The only solid nucleus he finds in it is the fact that there is a great deal of beauty in this world. Obviously this writer is harder to focus than Kant or Hegel. He is not all of one piece. He holds—on grounds of fact and science—to the mechanical orderliness of nature, but claims that the *Weltanschauung* thus suggested may be reinterpreted in view of those undying human aspirations which MacTaggart dismisses to instant execution (unless they can dress themselves in syllogism). Thus, for Lotze, free will is possible; the consequences of action proceed regularly *a parte post*, and there is no such chaos as the critics of Libertarianism have pretended it would involve. Similarly, miracles—absolute new beginnings—are possible on God's side, if they are not mere anomalies but acts promotive of the general meaning or tendency of things, and of the divine plan of the universe.[2] But this appeal to "values" is only half of Lotze's constructive work. For the other half he falls back on ratiocination. All existences must be individuals, with an inner life (cf. Leibnitz). Since they interact, they must be elements in the life of one supreme being (cf. Spinoza: the Spinozistic affinities of Leibnitz are not so marked as Lotze's). God can be personal and doubtless is (though he has no Non-ego to define himself against) through contrast of passing conscious states with the abiding Ego. It is reasonable to hold that the supreme personality is the only fully personal being, while ours is a broken and imperfect personality, hindered by the Non-ego which in other ways helps it. Lotze resolves space into "ideal space"; and finally, in the philosophy of religion, or in view of the thought of God (in his *Metaphysics*), he denies the objective existence of time. God sees all history neither as future nor as present but as actual.

Further developments from Kant.

Besides the stream of tendency which flowed from Kant in the direction of idealism, two other streams emerged from him, often but not always blending. There was a new scepticism—at the very least a doctrine of limitation in human knowledge; but in its extremer forms an absolute agnosticism. And there was the positive ethical element in Kant's theism.

Ancient scepticism was frankly opposed to religious belief. Later, the emergence of a great body of doctrine attributed to divine revelation and of a great institution like the Christian church suggested the possibility of enlisting scepticism in the service of dogmatic faith. In a sense (see APOLOGETICS) this was done in the middle ages, and possibly repeated by Pascal after the Reformation. We now find Kant's intellectual scepticism borrowed by W. Hamilton and H. L. Mansel,[3] both of them, as J. S. Mill complained,[4] "bringing back under the name of belief what they banished as knowledge." The theory found a melodious echo in Tennyson's *In Memoriam*, a great hymn of God, Freedom and Immortality on a basis of speculative agnosticism. "We have but faith we cannot know, For knowledge is of things we see;" but the moral element which Mansel despised is dominant in Tennyson. "The heart Stood up and answered, I have felt." If there is a reading of the new theories of evolution in nature which revives rather than darkens hope in immortality and faith in God, Tennyson gave an early sketch of that tentative modern theism.

R. Browning has been charged by H. Jones with partial agnosticism. But at least we may say that agnosticism is much less clear in Browning than in Tennyson. Browning reasons as far as he can; if reasoning fails him, he gives a leap of faith. Jones, almost as merciless as MacTaggart, calls this procedure by the hard names of agnosticism and dualism. Another who "got the seed" and "grew the flower" was Herbert Spencer. He quotes pages from Mansel's Bampton Lectures in favour of his own type of agnosticism, which is to make peace between religion and science by permanently silencing the former. Religion may "feel," like Tennyson's "man in wrath," and may expatiate in an undefined awe; science alone is to possess the "knowable." This yields a characteristic type of pantheism, in the theory of the Unknowable which—rather paradoxically—is offered us. Alongside of this there are other elements in Spencer's composite system of "Naturalism and Agnosticism" (J. Ward's expression, see his *Gifford Lecture*). The element of naturalism stands for science with a leaning towards materialism ("explanation in terms of matter and motion"). The element of agnosticism tends rather towards pantheism, just as Indian pantheism long ago tended towards agnosticism. John Fiske, however, an able interpreter of Spencer, reached what he called "Cosmic Theism." He rejected all that is anthropomorphic in theism, but gave a positive not negative interpretation to Spencer's scientific generalizations, and broke away from pantheism—perhaps also from naturalism—when, like Tennyson, he pleaded for *human immortality* as the climax of evolutionary progress.

[The name agnosticism (*q.v.*) is T. H. Huxley's. Modern doubt does not say there is no God; it says, We don't know. Popular scepticism—perhaps even Charles Darwin's; Huxley himself was a student of Hume—understands by agnosticism that science is certain while philosophy and theology are baseless. Leslie Stephen gave this popular agnosticism its finest literary expression. Spencer goes much further in rejection of human knowledge: "The man of science more than any other truly knows that in its ultimate essence nothing can be known."] [5]

An interesting manifesto of agnosticism, with a religious conclusion, is A. J. Balfour's *Foundations of Belief*, welcomed in Germany by Julius Kaftan (see below). In "Some Consequences of (naturalistic) Belief," Balfour argues that the results of "naturalism" are unbearable. In "Some Reasons for Belief," the author institutes a rapid destructive criticism of all possible philosophies. In "Some Causes of Belief," he tries, standing outside the psychological process, to show how beliefs grow up under every kind of influence except that of genuine evidence. His constructive theory comes at the end, and seems to argue thus: Since (1) there is no discoverable reason why we

[1] Stated and criticized by Kant.

[2] Lotze is not to be understood as guaranteeing the actuality of Bible miracles. Such things are philosophically possible—that is all.

[3] Mansel's theism (or natural theology), and the revelation he believes in, seem both of them pure matters of assertion on his part, without evidence, or even in the teeth of the evidence as he conceives it.

[4] *Examination of Sir Wm. Hamilton's Philosophy*, chap. v.

[5] *First Principles*, p. 67.

should reach truth, beauty or goodness, but (2) *we do*, therefore (3) there must be a God outside the process, overruling and counteracting the natural tendencies of the human mind. It seems as if one foot rested on dogmatism and one on scepticism. The fact—assumed without any attempt at justification by argument—that, in spite of the multitude of logical reasons for scepticism, we *do* know truth and beauty, makes Balfour a theist. And the God he postulates is brought in *ex machina* like the God of the old Design argument in its roughest popular form. There must be a God, who could compel irrational matter to serve rational ends—so ran the old argument. There must be a God who can miraculously endow the irrational mind of man with truth—so runs the new.

Emphasis on moral motives is plain in Kant's theism as in Butler's. If this tendency is to take effect, a certain part of Kant's rational scepticism must be accepted. There is no chance for the moral consciousness to claim a decisive vote if a metaphysical system like Hegel's demonstrates all realities in every region, and if its janissaries crush out every movement of rebellion against the tyranny of abstract thought. Is it really impossible to claim for man something between omniscience and universal nescience? May we not cherish what A. C. Fraser calls "reasonable faith"? Granted that, ideally, scientific knowledge ought to be able to demonstrate all truth, is it safe, or humane, for a being who is imperfectly started in the process of knowledge to fling away with scorn those unanalysed promptings and misgivings "Which, be they what they may, Are yet the fountain light of all our day, Are yet a master light of all our seeing . . . truths which wake To perish never"? Those who assert the superior worth and importance of moral judgments speak of "values" (A. Ritschl, after J. F. Herbart and H. Lotze). As worked out by Ritschl, this is specially a basis for Christian belief. With what is specifically Christian we have nothing to do in the present article: but it is worth noticing that the appeal to "values," aesthetic and still more moral, forms a substitute for that natural theology which Ritschl despised and professed to reject. There are not a few difficulties in his programme. When Otto Ritschl[1] interprets values hedonistically—recoiling from Hegel's idealism the whole way to empiricism—he brings again to our minds the doubt whether hedonist ethics can serve as a foundation for any religious belief. Julius Kaftan—Balfour's German editor, and a highly influential theologian, occupying a position of modified Ritschlianism—is also a very thoroughgoing empiricist. On the other hand, W. Herrmann's appeal to Kant's moral teaching is in close analogy to the more thoughtful forms of intuitionalist ethics. But is the basis for religious belief to be constructed purely within the region of "values"? Can you contrast "judgments of value" with "judgments of fact"? Or, if, as the Ritschlians maintain, it is a slander invented by their enemy, C. E. Luthardt, to say that they draw this contrast, do you achieve much by calling the principles of moral and religious belief, with A. Ritschl, "independent judgments of value"? Independent of what? Surely not of fact? It is explained that they are in contrast with "accessory value-judgments." Perhaps the meaning is that they are of *independent importance*. But does that carry us far? It all seems a very hurried and imperfectly studied philosophical analysis. One might prefer as a theist to hold (1) that we need a philosophical doctrine of the nature of reality—the "Absolute"; given in popular form in the Cosmological argument; (2) that we take the risk of attaching a higher degree of significance and authority to the revelations of the moral consciousness, which, although moulded or educed by society, do not terminate in the authority of society, but point beyond it to God; this position has its popular form in the moral argument; possibly (3) that necessities of thought shut us up to belief in omnipotence or infinity; (4) that divine *help* is the supreme revelation. But such lines of thought might carry us outside the limits of traditional theism.

[1] Son of A. Ritschl. The younger theologian has accepted determinism.

If we try to bring the contents of theism under Kant's three traditional arguments, then moral and aesthetic considerations—the "values"—fall under the Design argument or the study of teleology; albeit there is a great gap between Paley's supernatural watchmaker and any moral argument or appeal to the beautiful. It might be argued that beauty bears witness against materialism, and moral values against pantheism; although such an anomalous type as *ethical pantheism* has its representatives—J. G. Fichte, Matthew Arnold, perhaps H. Höffding. Kant's reliance on the moral argument *alone* goes with his scepticism. Giving that argument the *highest place* seems to involve, as already said, a dash of the same scepticism. —The arguments, as already noted, may be differently *combined*. (1) Usually they are alternatives or else cumulative. (2) Flint spaces out the proof (and the attributes) among them. (3) Hegel regards them as phases.

Alternatives to theism.

V. What are the alternative conclusions to theism? The extremest form of antagonism is pure scepticism or pure agnosticism, the assertion that nothing can be known. Empiricism may lead to this conclusion; or it may lead to materialism. True materialism includes within itself dogmatic atheism, and is probably the only coherent or reasoned type of atheistic opinion.[2] Materialism further brings with it an extreme or "hard" determinism; and, denying the soul's separate existence in any sense, it naturally denies immortality. Once again, empiricism may lead to some qualified and restricted form of agnosticism, religious or anti-religious. If polytheism is to be seriously defended at all, the basis must be empiricist.[3] Intuitionalism in its turn may harden out of "natural" dualism into moral dualism; either a literally Manichaean scheme—a good God impeded by an evil personality or principle (Bayle)—or belief in a good God of limited powers (Mill). And idealism in some cases may interpret itself in favour of pantheism rather than of theism. Pantheism does not favour free will or immortality, and may move indefinitely near to materialism. Out of pantheism again pessimism develops. If the principle of the universe is impersonal or unconscious, personal consciousness in finite spirits comes to wear the appearance of a blunder. Conversely, if God cares for men, despair is impossible. For another systematic grouping, see A. C. Fraser's *Gifford Lectures*. Wolff's list is of some historical importance—atheism, deism (a God without care for men) and naturalism (denial of supernatural revelation); anthropomorphism (assigning a human body to God); materialism, and idealism (non-existence of matter); paganism (polytheism); Manichaeism, Spinozism, Epicureanism. R. Flint has dealt with the following antitheistic theories: atheism, materialism, positivism, secularism, pessimism, pantheism and (in a separate volume) agnosticism. It is hard to be certain that any systematic grouping will anticipate all the suggestions that may occur to a restlessly and recklessly inquiring age.

LITERATURE.—Two sets of writers have been considered:—first, the greater philosophers, who have incidentally furthered theism (Socrates, Plato, Aristotle, the Stoics, Descartes, Locke, Kant, Hegel, Mill, Lotze), or opposed it (Epicurus, Spinoza, Hume, Kant, Hegel, Mill, Spencer); and, secondly, the deliberate champions of theism—Cicero (especially in the *De Natura Deorum*), Philo, Raymond of Sabunde (in a sense), Wolff, Butler (in a sense), Paley, and a host of English and German 18th-century authors, who chiefly handle the Design argument; then recent writers like R. Flint, *Theism*, *Antitheistic Theories*, *Agnosticism*—all with valuable notes and references, and J. Martineau—especially in *A Study of Religion*. The theistic writers are usually intuitionalists; but it has been urged above that a fruitful study of theism must *in each case* inquire what is the writer's philosophical basis. The Bridgewater treatises have little more than historical interest to-day. A certain historical interest also attaches to the Burnett prize essays on theism: 1815, 1st prize, W. L. Bruce, 2nd J. B. Sumner, afterwards archbishop; 1855, 1st R. A. Thompson, 2nd J. Tulloch. Among many lectureships, the Gifford Lectures are supposed to be strictly appropriated to Natural Theology; yet subjects and

[2] Dr MacTaggart's beliefs once more present themselves as an unexpected modern type (*Studies in Hegelian Cosmology*, chap. iii.).

[3] Yet cf. once more MacTaggart's society of eternal spirits with no divine head.

treatment vary immensely. A. C. Fraser's Edinburgh lectures (*Phil. of Theism*) are central in topic and of distinct value. J. Caird (Glasgow: *Fundamental Ideas of Christianity*, comp. his earlier *Introduc. to the Phil. of Relig.*) and more unreservedly Ed. Caird (St Andrews: *The Evolution of Religion;* Glasgow: *The Evolution of Theology in the Greek Philosophies*) represent speculative treatment on a basis of Hegelianism. H. M. Gwatkin (Edinburgh: *The Knowledge of God*) pours out his historical knowledge, and W. James (Edinburgh: *Varieties of Relig. Exp.*) reveals his many-sided intellectual interests and ready sympathies. W. Wallace (*Lectures and Essays*, incorporating Glasgow lectures) gives some useful historical references. James Ward's masterly criticism of Herbert Spencer (*Naturalism and Agnosticism*) has been mentioned above. The student will rarely lose by reading Gifford Lectures; but it will not always be upon theism that he finds himself better informed. In France, Paul Janet (*Final Causes*, Eng. trans.) and Ch. Sécretan (*Philosophie de la Liberté*) may be named: in Germany, H. Ulrici; while R. Eucken represents to a later generation the spirit and tendency of Lotze and Ulrici, in original and powerful, if rather elusive, fashion. H. Höffding's *Phil. of Religion* (translated) is one of the most original books under that title, but it cannot be called theistic. F. C. S. Schiller, like W. James, opens up new suggestions in philosophy; the bearing of these upon theistic (or other) beliefs is hard to define. In history compare B. Pünjer's *Hist. of the Phil. of Relig.* (Eng. trans.; it includes a good deal of the history of general philosophy); A. Caldecott's *The Philosophy of Religion in England and America;* and A. Caldecott and H. R. Mackintosh's *Selections from the Literature of Theism* (useful texts with useful notes: nothing from Hegel). (R. MA.)

THEISS (Hungarian, *Tisza;* Lat., *Tisia* or *Tissus*), a large affluent of the Danube, next to which it is the greatest river of Hungary. It rises in the north-eastern part of the Carpathian mountains, in the county of Máramaros, at a height of above 6300 ft., and is formed by the confluence of two branches, the Black Theiss (Fekete Tisza), and the White Theiss (Fehér Tisza), which unite at about 20 m. E. of Máramaros-Sziget. The Theiss then follows a north-westerly direction until it leaves its mountainous valley, then runs west, and after a great curve to the north, takes a south-westerly direction and enters the great Hungarian plain (Alföld). From Szolnok it runs south in an almost parallel course with that of the Danube, from which it is separated by a distance of about 60 m., and flows into the Danube near the village of Titel, 20 m. E. of Ujvidek. Its length from source to mouth is, as the crow flies, only about 340 m., but its windings make its course about 870 m. long. The Theiss is clear and swift in its course through the mountains, but in the plain it becomes slow, somewhat muddy and very tortuous. Its basin covers an area of 56,600 sq. m., and comprises the whole eastern part of Hungary, and the greater part of Transylvania, and collects all the rivers descending from the Carpathians westward.

The Theiss is navigable for rafts almost everywhere, but for steamers only from Szolnok downwards, a distance of about 200 m., where the breadth of the river is 450 to 750 ft. The depth of the Theiss at low-water mark is 7 ft. at Tokaj, 20 ft. at Szeged and 11 ft. at Titel, near its mouth, while the difference between the low-water mark and the high-water mark is as high as 25 to 35 ft. During its course through the great Hungarian plain the Theiss flows between flat, low-lying banks, which are the cause of periodical and sometimes disastrous inundations and of extensive marshes. Therefore extensive works have been undertaken for the regulation and canalization of the river, which is now strongly dammed in many parts. By these works large tracts of marshes have been transformed into productive ground. Its chief tributaries are the Szamos, Körös, Maros, Latorcza, and the Sajó. In its lower course it is joined to the Danube by the Franz Josef canal, while it is also united with Temesvár by the Bega canal.

THEMIS, in Greek mythology, the personification of justice. In Homer θέμις is used both as a common and as a proper noun. As a common noun (plural θέμιστες, θέμιτες, θέμιδες), it is the body of rules and precedents established at the beginning of the world, as a guarantee of its order and harmony (see GREEK LAW); personified, Themis is the servant or companion of Zeus, her chief function being to summon the assemblies of both gods and men (*Odyssey*, ii. 68). In the Hesiodic theogony, she is the daughter of Uranus and Gaea, and according to Pindar the wife of Zeus, by whose side she sits, assisting him with her advice, which is even better than that of any of the gods. She is the mother of the Horae and of the Moirae (Fates), an indication of her influence in the physical and moral world. She is the representative of divine justice in all its relations to men, and takes special cognizance of the rights of hospitality. Her opposite is Hybris (ὕβρις), insolent encroachment upon the rights of others, on whose track she follows to punish, like Nemesis. In this aspect both Themis and Nemesis are called ἰχναία (ἴχνος, track). In the lexicon of Festus, Themis is described as the goddess who prescribes that which is right in accordance with divine law (*fas*) and is herself identical with this divine law. She is also a prophetic divinity, and there was a tradition that the oracle at Delphi had first been in the hands of Gaea, who transferred it to Themis (sometimes identified with her) by whom it was handed over to Apollo (Aeschylus, *Eumenides*, 2; Euripides, *Iphig. in T.* 1181). Orphic poetry makes her a daughter of Helios, whose eye is all-seeing (πανδέρκης) and penetrates all mysteries. She was especially honoured at Athens, Delphi, Thebes, Aegina and Troezene, where there was an altar dedicated to a triad of Themides (on the analogy of the triads of Horae, Charites, Moirae). In art she was represented as of dignified and commanding presence, with the cornucopiae (symbolizing the blessings resulting from order) and a pair of scales.

See article "Justitia" by J. A. Hild in Daremberg and Saglio's *Dict. des Antiquités;* H. Ahrens, *Die Göttin Themis* (1862); R. Hirzel, *Themis, Dike, und Verwandtes* (1907).

THEMISTIUS (317–?387), named εὐφραδής ("eloquent"), statesman, rhetorician and philosopher, was born in Paphlagonia and taught at Constantinople, where, apart from a short sojourn in Rome, he resided during the rest of his life. Though a pagan, he was admitted to the senate by Constantius in 355. He was prefect of Constantinople in 384 on the nomination of Theodosius. His paraphrases of Aristotle's *Posterior Analytics, Physics* and *De Anima* are valuable; but the orations in which he panegyrizes successive emperors, comparing them to Plato's "true philosopher," and even to the "idea" itself, are servile and unworthy. Against this, however, should be set the description given by Boetius, "*disertissimus scriptor ac lucidus, et omnia ad facilitatem intelligentiae revocans*," and that of Gregory Nazianzen—with whom Themistius corresponded—βασιλέα λόγων. Themistius's paraphrases of the *De Coelo* and of book Λ of the *Metaphysics* have reached us only through Hebrew versions. In philosophy Themistius was an eclectic. He held that Plato and Aristotle were in substantial agreement, that God has made men free to adopt the mode of worship they prefer, and that Christianity and Hellenism were merely two forms of the one universal religion.

The first edition of Themistius's works (Venice, 1534) included the paraphrases and eight of the orations. Nineteen orations were known to Petavius, whose editions appeared in 1613 and 1618; Hardouin (Paris, 1684) gives thirty-three. Another oration was discovered by Angelo Mai, and published at Milan in 1816. The most recent editions are W. Dindorf's of the orations (Leipzig, 1832), and L. Spengel's of the paraphrases (Leipzig, 1866). The Latin translations of the Hebrew versions of the paraphrases of the *De Coelo* and book Λ of the *Metaphysics* were published at Venice in 1574 and 1558 respectively. A new edition of the latter by S. Landauer appeared in 1903. See Fabricius, *Bibliotheca Graeca*, vi. 790 seq.; E. Zeller, *History of Greek Phil.;* E. Baret, *De Themist, sophista* (Paris, 1853); Jourdain's *Recherches critiques sur l'âge et l'origine des traductions latines d'Aristote* (Paris, 1819); see NEOPLATONISM. For Themistius's Commentaries on Aristotle, see *Commentaria in Aristotelem Graeca* (Berlin), and also *Themistii paraphrases Aristotelis librorum quae supersunt*, ed. L. Spengel (1866, Teubner series, mentioned above).

THEMISTOCLES (*c.* 514–449 B.C.), Athenian soldier and statesman in some respects probably the ablest and most far-sighted whom Greece produced in the first half of the 5th century. He was the son of Neocles, an Athenian of no distinction and moderate means, his mother being a Carian or a Thracian. Hence according to the Periclean law ἐξ ἀμφοῖν ἀστοῖν he would not have been a free Athenian at all (see PERICLES). Thucydides properly brings out the fact that, though he lacked that education which was the peculiar glory of the Periclean age, he displayed a marvellous power of analysing a complex situation together with a genius for rapid action. Plutarch similarly enlarges on his consuming ambition for power both personal and national, and the unscrupulous ability with which he pursued his ends. In all these points he is the antithesis of his great rival Aristides (*q.v.*). Of his early years little is known. He may have been strategus of his tribe at Marathon (Plut. *Arist.* 5) and we are told that he deeply envied the glory which Miltiades earned. At all events the death of Miltiades left the stage to Aristides and Themistocles. It is sufficiently clear that their rivalry, terminated in 483-82 by the ostracism of Aristides, turned largely on the fact that Themistocles was the advocate of a policy of naval expansion. This policy was unquestionably of the highest importance to Athens and indeed to Greece. Athens was faced by the equal if not superior power of Aegina, while the danger of a renewed Persian invasion loomed large on the horizon. Themistocles therefore persuaded his countrymen to put in hand the building of 200 triremes, and —what was of even greater importance—to fortify the three natural harbours of Peiraeus (see E. Gardner, *Ancient Athens*, 562 f.) in place of the open roadstead of Phalerum. For the building of the ships Themistocles persuaded the Athenians to allocate 100 talents obtained from the new silver mines at Laurium (*Ath. Pol.* 22) which were about to be distributed to the citizens (10 drachmae each). One hundred of the proposed 200 were built.

According to the *Ath. Pol.* it would seem that Themistocles was archon in 483-82 at the time when this naval programme began. Dionysius of Halicarnassus places his archonship in 493-92, in favour of which are several considerations. In 487 the office lost much of its importance owing to the substitution of the lot for election: the chance that the lot would at the particular crisis of 483 fall on Themistocles was obviously remote: and the *Ath. Pol.* is generally wrong about Themistocles. In any case the year prior to the invasion of Xerxes found Themistocles the chief man in Athens if not in Greece. Though the Greek fleet was nominally under the control of the Spartan Eurybiades, it was Themistocles who caused the Greeks to fight the indecisive battle of Artemisium, and still more it was he who, by his threat that he would lead the Athenian army to found a new home in the West, and by his treacherous message to Xerxes, precipitated the engagement at Salamis (*q.v.*). The retirement of the Persians left the Athenians free to restore their ruined city (see ATHENS). Sparta, nominally on the ground that it was dangerous to Greece that there should be any citadel north of the Isthmus which an invader might hold, urged that this should not be done, but Themistocles by means of diplomatic delays and subterfuges enabled the work to be carried sufficiently near to completion to make the walls defensible. He also carried out his original plan of making Peiraeus a real harbour and fortress for Athens. Athens thus became the finest trade centre in Greece, and this fact, coupled with Themistocles' remission of the alien's tax (*μετοίκιον*), induced many foreign business men to settle in Athens.

After the crisis of the Persian invasion Themistocles and Aristides appear to have composed their differences. But Themistocles soon began to lose the confidence of the people, partly owing to his boastfulness (it is said that he built near his own house a sanctuary to Artemis Aristoboulē "of good counsel") and partly to his alleged readiness to take bribes. Diodorus (xi. 54) and Plutarch (*Themist.* 23) both refer to some accusation levelled against him,[1] and some time between 476 and 471 he was ostracized. He retired to Argos, but the Spartans further accused him of treasonable intrigues with Persia, and he fled to Corcyra, thence to Admetus, king of the Molossians, and finally to Asia Minor. He was proclaimed a traitor at Athens and his property was confiscated, though his friends saved him some portion of it. He was well received by the Persians and was allowed to settle in Magnesia on the Maeander. The revenues (50 talents) of this town were assigned to him for bread, those of Myus for condiments, those of Lampsacus for wine. He died at Magnesia at the age of sixty-five, and a splendid memorial was raised by the people of the town, though it is said that his bones were secretly transferred to Attica. He was worshipped by the Magnesians as a god, as we find from a coin on which he is shown with a patera in his hand and a slain bull at his feet (hence perhaps the legend that he died from drinking bull's blood: cf. Aristoph. *Eq.* 83; Diod. xi. 58; Plut. *Them.* 31).

Though his end was discreditable, though his great wealth can hardly have been obtained by loyal public service, there is no doubt that his services to Athens and to Greece were great. He created the Athenian fleet and with it the possibility of the Delian League (*q.v.*) which became the Athenian empire, and there are many indications (*e.g.* his well-attested plan of expansion in the west) that the later imperialist ideal originated in his fertile brain.

There are monographs by Bauer (Merseburg, 1881) and Wecklein (Munich, 1882); but the best discussions of his career will be found in the chief Greek histories, *e.g.* Busolt; on the difficult chronology of his later years see Grote, *History of Greece* (and the one-vol. ed. by Mitchell and Caspari, 1907, p. 283, note 1, with the authorities there quoted); on the Magnesian coin, Rhousopoulos, in *Athen. Mitteil.* (1896), p. 22. On the walls, see Ed. Meyer in *Hermes*, xl. (1905), pp. 561–569. (J. M. M.)

[1] There is, however, much difficulty regarding this accusation. It may be simply a misunderstanding of his ostracism.

THÉNARD, LOUIS JACQUES (1777–1857), French chemist, was born on the 4th of May 1777 at Louptière, near Nogent-sur-Seine, Aube. His father, a poor peasant, managed to have him educated at the academy of Sens, and sent him at the age of sixteen to study pharmacy in Paris. There he attended the lectures of A. F. Fourcroy and L. N. Vauquelin, and succeeded in gaining admission, in a humble capacity, to the latter's laboratory. But his progress was so rapid that in two or three years he was able to take his master's place at the lecture-table, and Fourcroy and Vauquelin were so satisfied with his performance that they procured for him a school appointment in 1797 as teacher of chemistry, and in 1798 one as *repétiteur* at the *École Polytechnique.* In 1804 Vauquelin resigned his professorship at the *Collège de France* and successfully used his influence to obtain the appointment for Thénard, who six years later, after Fourcroy's death, was further elected to the chairs of chemistry at the *École Polytechnique* and the *Faculté des Sciences.* He also succeeded Fourcroy as member of the Academy. In 1825 he received the title of baron from Charles X., and in 1832 Louis Philippe made him a peer of France. From 1827 to 1830 he represented the department of Yonne in the chamber of deputies, and as vice-president of the *conseil superieur de l'instruction publique*, he exercised a great influence on scientific education in France. He died in Paris on the 21st of June 1857. A statue was erected to his memory at Sens in 1861, and in 1865 the name of his native village was changed to Louptière-Thénard.

Above all things Thénard was a teacher; as he himself said, the professor, the assistants, the laboratory—everything must be sacrificed to the students. Like most great teachers he published a text-book, and his *Traité de Chimie élémentaire, théorique et pratique* (4 vols., Paris, 1813–16), which served as a standard for a quarter of a century, perhaps did even more for the advance of chemistry than his numerous original discoveries. Soon after his appointment as *repétiteur* at the *École Polytechnique* he began a lifelong friendship with J. L. Gay-Lussac, and the two carried out many researches together. Careful analysis led him to dispute some of C. L. Berthollet's theoretical views regarding the composition of the metallic oxides, and he also showed Berthollet's "zoonic acid" to be impure acetic acid (1802); but Berthollet (*q.v.*), so far from resenting these corrections from a younger man, invited him to become a member of the *Société d'Arcueil.* His first original paper (1799) was on the compounds of arsenic and antimony with oxygen and sulphur, and of his other separate investigations one of the most important was that on the compound ethers, begun in 1807. His researches on sebacic acid (1802) and on bile (1807), and his discovery of peroxide of hydrogen (1818) also deserve mention. The substance known as "Thénard's blue," he prepared in 1799 in response to a peremptory demand by J. A. Chaptal for a cheap colouring matter, as bright as ultramarine and capable of standing the heat of the porcelain furnace.

Most of Thénard's memoirs, a list of which may be found in the Royal Society's *Catalogue of Scientific Papers*, were published in the *Annales de Chimie et de Physique*, the *Mémoires d'Arcueil*, the *Comptes Rendus* and the *Mémoires* of the Academy of Sciences.

THEOBALD (d. 1161), archbishop of Canterbury, was of Norman parentage, but the date of his birth is unknown. Early in life he entered the great abbey of Bec, of which he became prior in 1127 and abbot ten years later. In 1138 he was selected by Stephen, king of England, to fill the vacant see of Canterbury. Apparently he owed this advancement to his character for meekness, and as archbishop he behaved with a moderation which is in striking contrast to the conduct of his rival, Henry of Blois, bishop of Winchester. During the struggle between Stephen and Matilda it was Bishop Henry who fought for the privileges of the Church; Theobald, while showing a preference for Stephen's title, made it his rule to support the *de facto* sovereign. But as Stephen's cause gained ground the archbishop showed greater independence. He refused to consecrate the king's nephew to the see of York, and in 1148 attended the papal council of Reims in defiance of a royal prohibition. This quarrel was ended by the intercession of the queen, Matilda of Boulogne, but another, of a more serious character, was provoked by Theobald's refusal to crown Count Eustace, the eldest son of Stephen, the archbishop pleading the pope's orders as the excuse for this contumacy. He was banished from the kingdom, but Pope Eugenius terrified Stephen into a reversal of the sentence. In 1153 Theobald succeeded in reconciling Stephen with Henry of Anjou, and in securing for the latter the succession to the throne. On the accession of Henry in 1154, Theobald naturally became his trusted counsellor; but ill-health prevented the archbishop from using his influence to its full extent. He placed the interests of the Church in the hands of Thomas Becket, his archdeacon, whom he induced Henry to employ as chancellor. Theobald died on the 18th of April 1161. He is said to have recommended Becket as his successor.

In history Theobald lives chiefly as the patron of three eminent men: Becket, who began life as a clerk in his household; Master Vacarius, the Italian jurist, who was the first to teach Roman law in England; and John of Salisbury, the most learned scholar of the age. Theobald's household was a university in little; and in it were trained not a few of the leading prelates of the next generation.

See the *Vita Theobaldi* printed in J. A. Giles, *Lanfranci Opera*, vol. i. (Oxford, 1844); W. Hook, *Lives of the Archbishops of Canterbury*, ii. c. vi. (London, 1862); and K. Norgate, *England under the Angevin Kings*, vol. i. (London, 1887). (H. W. C. D.)

THEOBALD, LEWIS (1688–1744), English man of letters, playwright and Shakespearian commentator, the son of an attorney, was born at Sittingbourne, Kent, and was baptized on the 2nd of April 1688. He was educated under a clergyman named Ellis at Isleworth, and became a good classical scholar. He followed his father's profession, but soon abandoned it for literature. In 1713 he translated the *Phaedo* of Plato, and entered into a contract with Bernard Lintot the publisher to translate the tragedies of Aeschylus. He seems to have made other promises not carried out, but in 1714 and 1715 appeared versions of the *Electra*, the *Ajax*, and the *Oedipus Rex* of Sophocles, and the *Plutus* and the *Clouds* of Aristophanes. He became a regular hack-writer, contributing to *Mist's Journal*, and producing plays and poems of very small merit. The publication of his play *The Perfidious Brother* (acted 1715; printed 1716) involved Theobald in considerable difficulty. He apparently received a rough draft of the play from Henry Meystayer, a London watchmaker, with a commission to arrange it for the stage. Theobald brought it out as his own work. In the next year Meystayer produced a version, and charged Theobald with plagiarism, but there is no means of ascertaining the exact rights of the case. His poverty compelled him to produce rapidly. He translated the first book of the *Odyssey* (1716), wrote tragi-comedies, operas and masques, and helped John Rich in the production of pantomimes, then an innovation at Drury Lane. But in 1726 he produced *Shakespeare Restored, or a Specimen of the many Errors as well Committed as Unamended by Mr Pope in his late edition of this Poet; designed not only to correct the said Edition, but to restore the true Reading of Shakespeare in all the Editions ever published* (1726). However ill Theobald may have succeeded as a poet and dramatist, he showed great discrimination as a textual editor. Some of his happiest emendations are to be found in this work, which conclusively proved Pope's incompetence as a Shakespearian editor. Two years later a second edition of Pope's work appeared. In it he stated that he had incorporated some of Theobald's readings, in all amounting to about twenty-five words, and that he added the rest which could "at worst but spoil half a sheet of paper that chances to be left vacant here." He also insinuated that Theobald had maliciously kept back his emendations during the progress of the edition. All this was a gross misstatement of fact. He had in reality incorporated the majority of Theobald's best emendations. In the first edition of the *Dunciad* (1728) Theobald figured as the hero, and he occupied the place of chief victim until replaced by Colley Cibber in 1741. In spite of the critics, Theobald's work was appreciated by the public. In 1731 he undertook to edit Shakespeare for Tonson the publisher. The work appeared in seven volumes in 1734, and completely superseded Pope's edition. From 1729 to the date of its publication Theobald had been engaged in correspondence on the subject with Warburton, who after his friend's death published an edition of Shakespeare, in the preface of which he asserted that Theobald owed his best corrections to him. Study of the correspondence proves, however, that the indebtedness was on Warburton's side. Subsequent editors reaped, in most cases without acknowledgment or with actual scorn, the fruit of Theobald's painstaking labour, his wide learning and his critical genius. But Pope's satire, as Johnson justly remarked, blasted the characters that it touched. Theobald remained the type of the dry-as-dust commentator. His merits obtained a tardy recognition on the publication of a detailed study of his critical work by Mr Churton Collins in an essay entitled "The Porson of Shakespearian Criticism" (*Essays and Studies*, 1895). Theobald gave proof of the same happy gift in classical scholarship in some emendations of Aeschylus, Eustathius, Athenaeus and others, contributed to a learned journal started by John Jortin in 1731. He was a candidate for the laureateship in 1730, but Cibber gained the coveted post. His last years were harassed by poverty and disease. He began a critical edition of the plays of Beaumont and Fletcher, completed by Seward and Sympson after his death, which took place on the 18th of September 1744.

His correspondence with Matthew Concanen, Styan Thirlby and William Warburton is to be found in Nichols's *Illustrations of Literature* (ii. 204–654), which also gives the fullest account of his life.

THEOCRACY (Gr. *θεοκρατία*, the rule of God, from *θεός*, god, and *-κρατια*, *κρατεῖν*, to rule), a term applied to a form of government or to a state ruled by such a form of government, in which God or the divine power is looked to as the source of all civil power, and the divine commandments regarded as the laws of the community. The typical example of such a state is that of the Jews till the establishment of the kingship under Saul (see Jews).

THEOCRITUS, the creator of pastoral poetry, flourished in the 3rd century B.C. Little is known of him beyond what can be inferred from his writings. We must, however, handle these with some caution, since some of the poems ("Idylls") commonly attributed to him have little claim to authenticity. It is clear that at a very early date two collections were made, one of which included a number of doubtful poems and formed a *corpus* of bucolic poetry, while the other was confined to those works which were considered to be by Theocritus himself. The record of these recensions is preserved by two epigrams, one of which proceeds from Artemidorus, a grammarian, who lived in the time of Sulla and is said to have been the first editor of these poems. He says, "Bucolic muses, once were ye scattered, but now one byre, one herd is yours." The second epigram is anonymous, and runs as follows:—"The Chian is another. I, Theocritus, who wrote these songs, am of Syracuse, a man of the people, the son of Praxagoras and famed Philinna. I never sought after a strange muse." The last line may mean that he wrote nothing but bucolic poems, or that he only wrote in Doric. The statement that he was a Syracusan is confirmed by allusions in the "Idylls" (xi. 7, xxviii. 16–18). The information concerning his parentage bears the stamp of genuineness, and disposes of a rival theory based upon a misinterpretation of Idyll vii.—which made him the son of one Simichus. A larger collection, possibly more extensive than that of Artemidorus, and including poems of doubtful authenticity, was known to Suïdas, who says: "Theocritus wrote the so-called bucolic poems in the Dorian dialect. Some persons also attribute to him the following: *Daughters of Proetus*, *Hopes*, *Hymns*, *Heroines*, *Dirges*, *Lyrics*, *Elegies*, *Iambics*, *Epigrams*." The first of these may have been known to Virgil, who refers to the *Proetides* in the *Eclogues*.[1] The spurious poem xxi. may have been one of the *Hopes* (cf. l. 66, ἐλπὶς τῶν ὕπνων), and poem xxvi. may have been one of the *Heroines* (cf. l. 36, ἡρῷναι): elegiacs are found in viii. 33–60, and the spurious epitaph on Bion may have been one of the *Dirges*. The other classes are all represented in the larger collection which has come down to us.

The poems which are generally held to be authentic may be classified thus:—

I. *Bucolics and Mimes*.—The distinction between these is that the scenes of the former are laid in the country and those of the latter in a town. The most famous of the *Bucolics* are i., vii., xi. and vi. In i. Thyrsis sings to a goatherd how Daphnis, the mythical herdsman, having defied the power of Aphrodite, dies rather than yield to a passion with which the goddess had inspired him. In xi. Polyphemus is depicted as in love with the sea-nymph Galatea and finding solace in song: in vi. he is cured of his passion and naively relates how he repulses the overtures now made to him by Galatea. The monster of the *Odyssey* has been "written up to date" after the Alexandrian manner and has become a gentle simpleton. Idyll vii., the Harvest Feast (Θαλύσια), is the most important of the bucolic poems. The scene is laid in the isle of Cos. The poet speaks in the first person and is styled Simichidas[2] by his friends. Other poets are introduced under feigned names. Thus ancient critics identified Sicelidas of Samos (l. 40) with Asclepiades the Samian, and Lycidas, "the goatherd of Cydonia," may well be the poet Astacides, whom Callimachus calls "the Cretan, the goatherd." Theocritus speaks of himself as having already gained fame, and says that his lays have been brought by report even unto the throne of Zeus.[3] He praises Philetas, the veteran poet of Cos, and criticizes "the fledgelings of the Muse, who cackle against the Chian bard and find their labour lost."[4] Other persons mentioned are Nicias, a physician of Miletus, whose name occurs in other poems, and Aratus, whom the Scholiast identifies with the author of the *Phenomena*.

The other bucolic poems need not be further discussed. Several of them consist of a singing-match, conducted according to the rules of amoebean poetry, in which the second singer takes the subject chosen by the first and contributes a variation in the same air. It may be noted that the peasants of Theocritus differ greatly in refinement. Those in v. are low fellows who indulge in coarse abuse. This Idyll and iv. are laid in the neighbourhood of Croton, and we may infer that Theocritus was personally acquainted with Magna Graecia. Suspicion has been cast upon poems viii. and ix. on various grounds. An extreme view holds that in ix. we have two genuine Theocritean fragments, ll. 7–13 and 15–20, describing the joys of summer and winter respectively, which have been provided with a clumsy preface, ll. 1–6, while an early editor of a bucolic collection has appended an epilogue in which he takes leave of the Bucolic Muses.[5] On the other hand, it is clear that both poems were in Virgil's Theocritus, and that they passed the scrutiny of the editor who formed the short collection of Theocritean Bucolics.

The mimes are three in number, viz., ii., xiv., xv. In ii. Simaetha, deserted by Delphis, tells the story of her love to the moon; in xiv. Aeschines narrates his quarrel with his sweetheart, and is advised to go to Egypt and enlist in the army of Ptolemy Philadelphus; in xv. Gorgo and Praxinoë go to the festival of Adonis. It may be noticed that in the best MSS. ii. comes immediately before xiv., an arrangement which is obviously right, since it places the three mimes together. The second place in the MSS. is occupied by Idyll vii., the "Harvest Feast." These three mimes are wonderfully natural and lifelike. There is nothing in ancient literature so vivid and real as the chatter of Gorgo and Praxinoë, and the *voces populi* in xv.

It will be convenient to add to the *Bucolics* and *Mimes* three poems which cannot be brought into any other class, viz.: xii. (Αἴτης), a poem to a beautiful youth; xviii., the marriage-song of Helen (Ἐπιθαλάμιος); and xxvi., the murder of Pentheus (Λῆναι). The genuineness of the last has been attacked by U. von Wilamowitz-Möllendorff on account of the crudity of the language, which sometimes degenerates into doggerel. It is, however, likely that Theocritus intentionally used realistic language for the sake of dramatic effect, and the MSS. evidence is in favour of the poem. Eustathius quotes from it as the work of Theocritus.

II. *Epics*.—Three of these are Hymns, viz., xvi., xvii. and xxii. In xvi. the poet praises Hiero II. of Syracuse, in xvii. Ptolemy Philadelphus, and in xxii. the Dioscuri. The other poems are xiii., the story of Hylas and the Nymphs, and xxiv. the youthful Heracles. It cannot be said that Theocritus exhibits signal merit in his *Epics*. In xiii. he shows some skill in word-painting, in xvi. there is some delicate fancy in the description of his poems as "Graces" (Χάριτες), and a passage at the end, where he foretells the joys of peace after the enemy have been driven out of Sicily, has the true bucolic ring. The most that can be said of xxii. and xxiv. is that they are very dramatic. Otherwise they differ little from work done by other poets, such as Callimachus and Apollonius Rhodius. The flattery heaped upon Ptolemy is somewhat nauseous. From another point of view, however, these two poems xvi. and xvii. are supremely interesting, since they are the only ones which can be dated. In xvii. Theocritus celebrates the incestuous marriage of Ptolemy Philadelphus with his sister Arsinoë. This marriage is held to have taken place in 277 B.C., and a recently discovered inscription shows that Arsinoë died in 270, in the fifteenth year of her brother's reign.[6] This poem, therefore, together with xv., which Theocritus wrote to please Arsinoë (*Schol.* χαριζόμενος τῇ βασιλίδι) must fall within this period. The encomium upon Hiero II. would from internal reasons seem prior to that upon Ptolemy, since in it Theocritus is a hungry poet seeking for a patron, while in the other he is well satisfied with the world. Now Hiero first came to the front in 275 B.C. when he was made "General" (στρατηγός): Theocritus speaks of his achievements as still to come,[7] and the silence of the poet would show that Hiero's marriage to Philistis, his victory over the Mamertines at the Longanus and his election as "King" (βασιλεύς), events which are ascribed to 270 B.C., had not yet taken place. If so, xvii. and xv. can only have been written within 275 and 270.

III. *Lyrics*.—Two of these are certainly by Theocritus, viz., xxviii. and xxix. The first is a very graceful poem presented together with a distaff to Theugenis, wife of Nicias, a doctor of Miletus, on the occasion of a voyage thither undertaken by the poet. The theme of xxix. is similar to that of xii. A very corrupt poem, only found in one very late MS., was discovered by Ziegler in 1864. As the subject and style very closely resemble that of xxix., it is assigned to Theocritus by recent editors.

IV. The *Epigrams* do not call for detailed notice. They do not possess any special merit, and their authenticity is often doubtful. It remains to notice the poems which are now generally considered to be spurious. They are as follows:—

xix. "Love stealing Honey" (Κηριοκλέπτης). The poem is anonymous in the MSS. and the conception of Love is not Theocritean.

xx. "Herdsman" (Βουκολίσκος), xxi. "Fishermen" (Ἁλιεῖς), xxiii. "Passionate Lover" (Ἐραστής). These three poems are remarkable for the corrupt state of their text, which makes it likely that they have come from the same source and possibly are by the same author. The "Fishermen" has been much admired. It is addressed to Diophantus and conveys a moral, that one should work and not dream, illustrated by the story of an old fisherman who dreams that he has caught a fish of gold and narrates his vision to his mate. As Leonidas of Tarentum wrote epigrams on fishermen, and one of them is a dedication of his tackle to Poseidon by Diophantus, the fisher,[8] it is likely that the author of this poem was an imitator of Leonidas. It can hardly be by Leonidas himself, who was a contemporary of Theocritus, as it bears marks of lateness.

xxv. "Heracles the Lion-slayer" (Λεοντοφόνος). This is a long

[1] "Proetides implerunt falsis mugitibus agros."—*Ecl.* vi. 48.

[2] Two explanations are offered by the Scholiast: either that the poet was "snub-nosed" (σιμός), or that he was the son of Simichus. The second is obviously a mere guess.

[3] τά που καὶ Ζηνὸς ἐπὶ θρόνον ἄγαγε φάμα, l. 93. It is possible that Zeus refers to Ptolemy: cf. Horace, *Ep.* i. 19, 43, *Iovis auribus ista Servas*, where *Iupiter* = Augustus.

[4] Some think that there is an allusion to Apollonius Rhodius.

[5] Cf. Hiller, *ad loc.*

[6] The evidence is contained in a new fragment of the Mendes Stele. Cf. von Prott in *Rheinisches Museum* (1898), p. 464.

[7] ἔσσεται οὗτος ἀνὴρ ὃς ἐμεῦ κεχρήσετ' ἀοιδοῦ, l. 73.

[8] ὁ γριπεὺς Διόφαντος ἀνάκτορι θήκατο τέχνας (*Anth. Pal.* vi. 4, 7).

poem consisting of two episodes, viz. the interview of Heracles with the bailiff of Augeas and his recital to Phyleus, son of Augeas, of the story of the Nemean lion. The composition is not unworthy of Theocritus. It is, however, anonymous in the MSS. and comes next to another anonymous poem called "Megara, the wife of Hercules." It is probable from some metrical and linguistic peculiarities that xxv. and the "Megara" are both by the same author.

xxvii. "The wooing of Daphnis" ('Οαριστύς) is also anonymous. It contains imitations of Theocritus, but the tone and the language betray a later writer.

We have no sure facts as to the life of Theocritus beyond those supplied by Idylls xvi. and xvii. It is quite uncertain whether the bucolic poems were written in the pleasant isle of Cos among a circle of poets and students, or in Alexandria and meant for dwellers in streets. The usual view is that Theocritus went first from Syracuse to Cos, and then, after suing in vain for the favour of Hiero, took up his residence permanently in Egypt. Some have supposed on very flimsy evidence that he quarrelled with the Egyptian court and retired to Cos, and would assign various poems to the "later-Coan" period.[1] Wilamowitz-Möllendorff, laying stress on the fact that in the best MS. the poem to Ptolemy (xvii.) comes before that to Hiero (xvi.), very ingeniously puts the Egyptian period first and supposes it to have been of very short duration (*i.e.* 277 to 275), and then makes the poet, after his unsuccessful appeal to Hiero, retire to Cos for the rest of his life. This view would enable us to see a reference to Ptolemy in vii. 93, and even to the young Apollonius Rhodius in 47–48 of the same poem.

The poems of Theocritus were termed *Idylls* (εἰδύλλια) by the grammarians. The word is a diminutive from εἶδος, and is supposed to mean "little poems." The use of εἶδος in the sense of "poem" is somewhat doubtful, and so some have referred εἰδύλλια to εἶδος in its usual sense of "form" or "type." Thus εἶδος βουκολικόν, ἐπικόν, λυρικόν might be used to classify various kinds of poetry, and these poems might be called εἰδύλλια, since they include so many types.

Language and Metre.—Theocritus wrote in various dialects according to the subject. The Lyrics xxviii., xxix. (and xxx.) are in Aeolic, that being the traditional dialect for such poems. Two poems, xii. (Αἴτης) and xxii. (to Castor and Pollux), were written in Ionic, as is stated in titles prefixed to them, though a number of Doric forms have been inserted by the scribes. The epics in general show a mixture of Homeric, Ionic and Doric forms. The *Bucolics*, *Mimes*, and the "Marriage-song of Helen" (xviii.) are in Doric, with occasional forms from other dialects.

The metre used by Theocritus in the *Bucolics* and *Mimes*, as well as in the *Epics*, is the dactylic hexameter. His treatment of this may be compared both with Homeric usage and that of other Alexandrian poets, *e.g.* Callimachus. It was the tendency of these writers to use dactyls in preference to spondees with a view to lightness and rapidity. This tendency shows itself most in the third foot, the favourite caesura being the trochaic, *i.e.* after the second syllable (- ∪ !). On the other hand, the Alexandrians admitted a spondee in the fifth foot, especially when the verse ends with a quadrisyllable. Theocritus in the *Epics* conforms to the new technique in both these respects: in the *Bucolics* his practice agrees with that of Homer. The feature in his versification which has attracted most attention is the so-called bucolic caesura. The rule is that, if there is a pause at the end of the fourth foot, this foot must be a dactyl. This pause is no new invention, being exceedingly common in Homer. Theocritus uses it so frequently in the *Bucolics* that it has become a mannerism. In the *Epics* his practice agrees with that of Homer.

We always think of Theocritus as an original poet, and as the "inventor of bucolic poetry" he deserves this reputation. At the same time he had no scruple about borrowing from predecessors or contemporaries; in fact he did so in the most open manner. Thus xxix. begins with a line of Alcaeus,[2] and xvii., as the Scholiast points out, with words used by Aratus at the beginning of the *Phenomena*. The love of the Cyclops for Galatea had been treated by Philoxenus, and fragments quoted from this show that Theocritus copied some of his phrases closely. In the mimes Theocritus appears to have made great use of Sophron. Idyll ii. is modelled upon a mime of this writer which began in a very similar way.[3] The Scholiast thought that Theocritus showed want of taste in making Thestylis a *persona muta*, instead of giving her a share in the dialogue as Sophron had done. The famous poem about Gorgo and Praxinoë at the feast of Adonis was modelled on one by Sophron about women looking on at the Isthmian games ('Ισθμιάζουσαι), and fragments quoted from this are closely imitated by Theocritus. It is extremely interesting to find a similar poem in the recently discovered mimes of Herondas, the fourth of which is termed "Women making offerings to Aesculapius" ('Ασκληπιῷ ἀνατιθεῖσαι καὶ θυσιάζουσαι). The relation of Theocritus to Herondas is a subject of great interest. Herondas must have been a contemporary, as he refers to Ptolemy Philadelphus,[4] and was a native of Cos, so that he and Theocritus must have been acquainted. There are some curious parallels in the language and idioms of the two poets, but which of them copied the other it is impossible to determine.

Manuscripts.—The oldest authority for any part of Theocritus is a papyrus discovered by B. P. Grenfell and A. S. Hunt at Oxyrhynchus, written in the 2nd century A.D. and containing xiii. 19–34.[6] There are also fragments of another papyrus belonging to the 5th century, which contain some lines of i., v., xiii., xv., xvi. and xxvi.[6] These papyri are carelessly written and do not contain any notable variants. The most valuable of the existing MSS. belongs to the Library at Milan (*Ambros.* 222). It was written in the 13th century, and contains Idylls i.–xvii., xxix., and the *Epigrams*. Other good MSS. of the same family contain xviii. also. The other poems come from two sources. One of these is represented by several MSS. and contains xix., xx., xxi., xxii., xxiii., xxv. The other contains xxii. 69–223, xxiv., xxv., xxvi., xxvii., xxviii., xxix. This collection was first published in the *Juntine* edition (1515) from a *codex Patavinus* now lost. The only existing MS. of any value in which it is found is in Paris (2726), and was written in the 14th century. These two collections are termed φ and π by Hiller and other recent writers. It will be noticed that xxv. and a portion of xxii. are found both in φ and π. In these poems there are constant divergences, and π appears to give the better recension.

There are important Scholia to Theocritus, or rather to that portion of the poems (i.–xvii. and xxix.) which is found in the best MSS. The most valuable of these are those contained by *Ambros.* 222 (K). They are composite in character. The Argument to xii. is ascribed to Eratosthenes, a contemporary of Justinian, while reference is frequently made to the views of Munatius, who lived in the time of Herodes Atticus, and Amarantus, a contemporary of Galen. Wilamowitz-Möllendorff ascribes the nucleus of these Scholia to Theon, who wrote similar scholia on Lycophron and Apollonius Rhodius, and is stated to have written a commentary on Theocritus.[7] This Theon is stated to have been the son of Artemidorus, the first editor of Theocritus. It is, therefore, suggested that Theon formed the shorter collection of Theocritean poems, furnished them with *scholia*, and wrote the second epigram quoted at the beginning of this article. The other poems, which possess no *scholia* and have come down to us from the other collections, would, according to this ingenious theory, be those which appeared in the larger collection of Artemidorus but were excluded by Theon.

(A. C. C.)

THEODECTES (*c.* 380–340 B.C.), Greek rhetorician and tragic poet, of Phaselis in Lycia, pupil of Isocrates and Plato, and an intimate friend of Aristotle. He at first wrote speeches for the law courts, but subsequently composed tragedies with success. He spent most of his life at Athens, and was buried on the sacred road to Eleusis. The inhabitants of Phaselis honoured him with a statue, which was decorated with garlands by Alexander the Great on his way to the East. In the contests arranged by Artemisia, queen of Caria, at the funeral of Mausolus, Theodectes gained the prize with his tragedy *Mausolus* (extant in the 2nd century A.D.), but was defeated by Theopompus in oratory. According to the inscription on his tomb, he was

[1] The chief argument is that in xii. 5 the poet says—

ὅσσον παρθενικὴ προφέρει τριγάμοιο γυναικός.

As Arsinoë had been married three times, it is thought that she might have been offended by this remark.

[2] οἶνος, ὦ φίλε παῖ, λέγεται καὶ ἀλαθέα.

[3] Sophron's mime began with πεῖ γὰρ ἁ ἄσφαλτος; Theocritus's begins with πᾷ μοι ταὶ δάφναι;

[4] l. 30, Θεῶν ἀδελφῶν τέμενος, ὁ βασιλεὺς χρηστός.

[6] *Oxyrhynchus Papyri*, iv. p. 139.

[6] C. Wessely in *Berliner Philologische Wochenschrift* (1906), p. 831.

[7] Θέων ἐν τῇ ὑπομνήσει Θεοκρίτου, Etym. on i. 39: Θέων ὁ 'Αρτεμιδώρου, *ib.* on iv. 5. Cf. Ahrens, ii. p. xxvii.

eight times victorious in thirteen dramatic contests. Of his tragedies (fifty in number) thirteen titles and some fragments remain (A. Nauck, *Tragicorum Graecorum Fragmenta*, 1887). His treatise on the art of rhetoric (according to Suïdas written in verse) and his speeches are lost. The names of two of the latter—*Socrates* and *Nomos* (referring to a law proposed by Theodectes for the reform of the mercenary service)—are preserved by Aristotle (*Rhetoric*, ii. 23, 13, 17). The *Theodectea* (Aristotle, *Rhet.* iii. 9, 9) was probably not by Theodectes, but an earlier work of Aristotle, which was superseded by the extant *Rhetorica*.

See monograph by C. F. Märcker (Breslau, 1835). There is a lengthy article on Theodectes in Smith's *Dictionary of Greek and Roman Biography*, in which the connexion of the tragedy with the Artemisian contest is disputed.

THEODOLITE,[1] a surveying instrument consisting of two graduated circles placed at right angles to each other, for the measurement of horizontal and vertical angles, a telescope, which turns on axes mounted centrically to the circles, and an alidade for each circle, which carries two or more verniers. The whole is supported by a pedestal resting on footscrews, which are also employed to level the instrument. The size varies from a minimum with circles 3 in. in diameter to a maximum with a 36-in. horizontal and an 18-in. vertical circle.

Theodolites are designed to measure horizontal angles with greater accuracy than vertical, because it is on the former that the most important work of a survey depends; measures of vertical angles are liable to be much impaired by atmospheric refraction, more particularly on long lines, so that when heights have to be determined with much accuracy the theodolite must be discarded for a levelling instrument. When truly adjusted the theodolite measures the horizontal angle between any two objects, however much they may differ in altitude, as the pole star and any terrestrial object.

The instrument is made in three forms—the Y pattern, the Everest and the transit. Certain parts are common to all the forms in use and to the level. The stand is generally made circular in section, each of the three legs being shod at the lower extremity with steel. Their upper ends are hinged to a flat plate provided with a screwed collar of large diameter (fig. 1). To the legs is screwed a plate OO, which supports the lower side of the plate PP. This receives the ends of the screws SS by which the instrument is levelled, its annular portion being larger than the collar in OO, so that, until clamped by the screwed plate above it, the whole of the instrument except the legs can be moved horizontally in any direction to the extent of about ½ in. This facilitates centring over a point. The upper plate PP is bored centrally to receive a parallel or conical pillar which supports the lower circle of the theodolite or the arm of the level which carries the telescope. In the theodolite the edge of the plate *rr* is bevelled and divided into 360 or 400 degrees, and to half degrees, or to 20 minutes or 10 minutes, according to the size of the instrument. A collar is provided, which when tightened on the vertical axis, otherwise free to move, holds it rigidly in position with respect to the plate PP. To this collar is attached a slow-motion screw, working against a reaction spring, by which the plate *rr* can be rotated through a small arc. The upper plate carrying two, three or four verniers *vv* is attached to a vertical coned pillar passing through the centre of the larger pillar and rotating in it; this plate can be clamped to the lower plate by means of the screw C, and can be rotated with respect to it by the slow-motion screw *d*. On the upper plate are placed two small levelling bubbles, and two standards *tt* are attached to the upper side of the plate for supporting the trunnions of the telescope T. The bearings for receiving these trunnions are V-shaped; the V on one side is fixed, while the other is cut through and can be narrowed or made wider, thus lifting or lowering the trunnion by means of two capstan-headed screws. To the telescope the vertical circle for reading angles in altitude is fixed, and rotates with it; both can be clamped to the standard, and motion can be given by a suitable double-ended motion screw. The verniers are attached to arms *uu* bearing on an enlargement of one trunnion of the telescope, one arm projecting downwards and embracing a projection on the standard *t*. To the same frame is attached a bubble, which should be parallel with the centre line of the verniers. The diagonal telescope *nn* is provided with cross hairs, and is used for the final centring of the instrument over an object. The use of aluminium in the construction of all parts not liable to much wear is to be commended, owing to the smaller weight. The Y theodolite differs from the transit in that the supports for the telescope are low, that the telescope rests in a cradle the trunnions of which rest on the supports, and that a segment of a circle attached to the cradle replaces

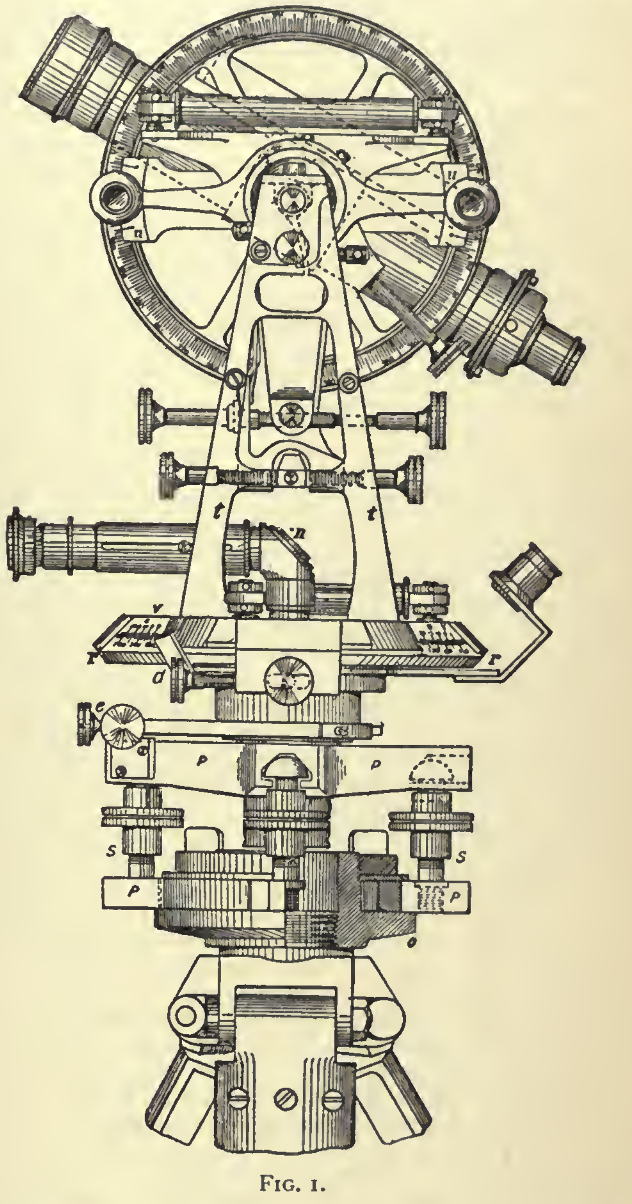

FIG. 1.

the vertical circle. When it is desired to read a line in the reverse direction the telescope is lifted out of the cradle, turned end for end, and replaced in the Y bearings of the cradle again. In the Everest theodolite the supports are low and the telescope cannot be transited. The instrument is similar to that described above, except that the vertical circle is not continuous, but is formed of two arcs.

In Germany and elsewhere refracting theodolites and transit instruments are sometimes employed. The eye end of the telescope tube is removed—a counterpoise to the object end being substituted in its place—and a prism is inserted at the intersection of the visual axis with the transit axis, so that the rays from the object-glass may be reflected through one of the tubes of the transit axis to an eye-piece in the pivot of this tube. In this case the pillars need only be high enough for the counterpoise to pass freely over the plate of the horizontal circle: but the observer has always

[1] This word has been a puzzle to etymologists. Various ingenious explanations have been given, all based on the apparent Greek form of the word; thus it has been derived from θεᾶσθαι, to see, ὁδός, way, and λιτός, smooth, plain; from θεῖν, to run, and δολιχός, long, and in other ways equally fanciful. Another imaginary origin has been suggested in a corruption of "the O deleted," *i.e.* crossed out, the circle being crossed by diameters to show the degrees; others have found in it a corruption of "the alidade" (*q.v.*). It would appear, however, to be taken from the O. Fr. *theodolet* or *theodelet*, the name of a treatise by one Theodulus, probably a mathematician (see *Notes and Queries*, 3rd series, vii. 337, 428, &c. Skeat, *Etym. Dict.*, 1910).

to place himself at right angles to the direction of the object he is observing.

Levelling Instrument.—This is another surveying instrument consisting essentially of a telescope bearing a level and mounted horizontally upon a frame. To the upper side of the parallel plates it is similar in construction to the theodolite. No provision is made for centring over a point. The upper plate is bored through the centre and carries a conical pillar, which rotates freely in it and supports a horizontal plate, to the extreme ends of which are attached, by means of capstan screws or otherwise, two vertical supports, on which the telescope, which is constructed to be perpendicular to the vertical axis of the instrument, rests and rotates with it. The level bubble, by which the instrument is brought into a position at right angles to the axis of the earth, is generally placed on the top of the telescope. In the best telescopes, whether for theodolite or level, the diaphragm on which the image is formed is made of glass, and the cross hairs are engraved thereon. In the level the eye-piece and object-glass are interchangeable, to facilitate adjustment for collimation.

THEODORA, the wife of the emperor Justinian (*q.v.*), was born probably in Constantinople, though according to some in Cyprus, in the early years of the 6th century, and died in 547. According to Procopius, our chief, but by no means a trustworthy authority for her life, she was the daughter of Acacius, a bear-feeder of the amphitheatre at Constantinople to the Green Faction, and while still a child was sent on to the stage to earn her living in the performances called mimes. She had no gift for either music or dancing, but made herself notorious by the spirit and impudence of her acting in the rough farces, as one may call them, which delighted the crowd of the capital. Becoming a noted courtesan, she accompanied a certain Hecebolus to Pentapolis (in North Africa), of which he had been appointed governor, and, having quarrelled with him, betook herself first to Alexandria, and then back to Constantinople through the cities of Asia Minor. In Constantinople (where, according to a late but apparently not quite groundless story, she now endeavoured to support herself by spinning, and may therefore have been trying to reform her life) she attracted the notice of Justinian, then patrician, and, as the all-powerful nephew of the emperor Justin, practically ruler of the empire. He desired to marry her, but could not overcome the opposition of his aunt, the empress Euphemia. After her death (usually assigned to the year 523) the emperor yielded, and as a law, dating from the time of Constantine, forbade the marriage of women who had followed the stage with senators, this law was repealed. Thereupon Justinian married Theodora, whom he had already caused to be raised to the patriciate. They were some time after (527) admitted by Justin to a share in the sovereignty; and, on his death four months later, Justinian and Theodora became sole rulers of the Roman world. He was then about forty-four years of age, and she some twenty years younger. Procopius relates in his unpublished history (Ἀνέκδοτα) many repulsive tales regarding Theodora's earlier life, but his evident hatred of her, though she had been more than ten years dead when the *Anecdota* were written, and the extravagances which the book contains, oblige us to regard him as a very doubtful witness. Some confirmation of the reported opposition of the imperial family to the marriage has been found in the story regarding the conduct of Justinian's own mother Vigilantia, which Nicholas Alemanni, the first editor of the *Anecdota*, in his notes to that book, quotes from a certain "Life of Justinian" by Theophilus, to which he frequently refers, without saying where he found it. Mr Bryce, however, discovered in Rome what is believed to be the only MS. of this so-called life of Justinian; and his examination of its contents makes him think it worthless as an authority (see THEOPHILUS).

Theodora speedily acquired unbounded influence over her husband. He consulted her in everything, and allowed her to interfere directly, as and when she pleased, in the government of the empire. She had a right to interfere, for she was not merely his consort, but empress regnant, and as such entitled equally with himself to the exercise of all prerogatives. In the most terrible crisis of Justinian's reign, the great Nika insurrection of 532, her courage and firmness in refusing to fly when the rebels were attacking the palace saved her husband's crown, and no doubt strengthened her command over his mind. Officials took an oath of allegiance to her as well as to the emperor (*Nov.*, viii.). She even corresponded with foreign ambassadors, and instructed Belisarius how to deal with the popes. Procopius describes her as acting with harshness, seizing on trivial pretexts persons who had offended her, stripping some of their property, and throwing others into dungeons, where they were cruelly tortured or kept for years without the knowledge of their friends. The city was full of her spies, who reported to her everything said against herself or the administration. She surrounded herself with ceremonious pomp, and required all who approached to abase themselves in a manner new even to that half-Oriental court. She was an incessant and tyrannical match-maker, forcing men to accept wives and women to accept husbands at her caprice. She constituted herself the protectress of faithless wives against outraged husbands, yet professed great zeal for the moral reformation of the city, enforcing severely the laws against vice, and immuring in a "house of repentance" on the Asiatic side of the Bosphorus five hundred courtesans whom she had swept out of the streets of the capital. How much of all this is true we have no means of determining, for it rests on the sole word of Procopius. But there are slight indications in other writers that she had a reputation for severity.

In the religious strife which distracted the empire Theodora took part with the Monophysites, and her coterie usually contained several leading prelates and monks of that party. As Justinian was a warm upholder of the decrees of Chalcedon, this difference of the royal pair excited much remark and indeed much suspicion. Many saw in it a design to penetrate the secrets of both ecclesiastical factions, and so to rule more securely. In other matters also the wife spoke and acted very differently from the husband; but their differences do not seem to have disturbed either his affection or his confidence. The maxim in Constantinople was that the empress was a stronger and a safer friend than the emperor; for, while he abandoned his favourites to her wrath, she stood by her protégés, and never failed to punish anyone whose heedless tongue had assailed her character.

Theodora bore to Justinian no son, but one daughter—at least it would seem that her grandson, who is twice mentioned, was the offspring of a legitimate daughter, whose name, however, is not given. According to Procopius, she had before her marriage become the mother of a son, who when grown up returned from Arabia, revealed himself to her, and forthwith disappeared for ever; but this is a story to be received with distrust. That her behaviour as a wife was irreproachable may be gathered from the fact that Procopius mentions only one scandal affecting it, the case of Areobindus. Even he does not seem to believe this case, for, while referring to it as a mere rumour, the only proof he gives is that, suspecting Areobindus of some offence, she had torture applied to this supposed paramour. Her health was delicate, and, though she took all possible care of it, frequently quitting the capital for the seclusion of her villas on the Asiatic shore, she died comparatively young. Theodora was small in stature and rather pale, but with a graceful figure, beautiful features, and a piercing glance. There remains in the apse of the famous church of S. Vitale at Ravenna a contemporaneous mosaic portrait of her, to which the artist, notwithstanding the stiffness of the material, has succeeded in giving some character.

The above account is in substance that which historians of the two centuries and a half prior to 1885 accepted and repeated regarding this famous empress. But it must be admitted to be open to serious doubts. Everything relating to the early career of Theodora, the faults of her girlhood, the charges of cruelty and insolence in her government of the empire, rest on the sole authority of the *Anecdota* of Procopius—a book whose credit is shaken by its bitterness and extravagance. If we reject it, little is left against her, except of course that action in ecclesiastical affairs which excited the wrath of Baronius, who had denounced her before the *Anecdota* was published.

In favour of the picture which Procopius gives of the empress it may be argued (1) that she certainly did interfere constantly and arbitrarily in the administration of public affairs, and showed herself therein the kind of person who would be cruel and unscrupulous in her choice of means, and (2) that we gather from other writers an impression that she was harsh and tyrannical, as, for instance, from the references to her in the lives of the popes in the *Liber Pontificalis* (which used to pass under the name of Anastasius, the papal librarian). Her threat to the person whom she commanded to bring Vigilius to her was "nisi hoc feceris, per Viventem in saecula excoriari te faciam." Much of what we find in these lives is legendary, but they are some evidence of Theodora's reputation. Again, (3) the statute (*Cod.*, v. 4, 23) which repeals the older law so far as relates to *scenicae mulieres* is now generally attributed to Justin, and agrees with the statement of Procopius that an alteration of the law was made to legalize her marriage. There is therefore reason for holding that she was an actress, and, considering what the Byzantine stage was (as appears even by the statute in question), her life cannot have been irreproachable.

Against the evidence of Procopius, with such confirmations as have been indicated, there is to be set the silence of other writers, contemporaries like Agathias and Evagrius, as well as such later historians as Theophanes, none of whom repeat the charges as to Theodora's life before her marriage. To this consideration no great weight need be attached. It is difficult to establish any view of the controversy without a long and minute examination of the authorities, and in particular of the *Anecdota*. But the most probable conclusions seem to be—(1) that the odious details which Procopius gives, and which Gibbon did not blush to copy, deserve no more weight than would be given nowadays to the malignant scandal of disappointed courtiers under a despotic government, where scandal is all the blacker because it is propagated in secret; (2) that apparently she was an actress and a courtesan, and not improbably conspicuous in both those characters; and (3) that it is impossible to determine how far the specific charges of cruelty and oppression brought against her by Procopius deserve credence. We are not bound to accept them, for they are uncorroborated; yet the accounts of Justinian's government given in the *Anecdota* agree in too many respects with what we know *aliunde* to enable us to reject them altogether; and it must be admitted that there is a certain internal consistency in the whole picture which the *Anecdota* present of the empress. About the beauty, the intellectual gifts, and the imperious will of Theodora there can be no doubt, for as to these all our authorities agree. She was evidently an extraordinary person, born to shine in any station of life.

Her fortunes have employed many pens. Among the later serious works dealing with them may be mentioned M. Antonin Débidour's *L'Impératrice Theodora: Étude Critique* (Paris, 1885), which endeavours to vindicate her from the aspersions of Procopius; and among more imaginative writings are Sir Henry Pottinger's interesting romance *Blue and Green* (London, Hurst and Blackett, 1879), M. Rhangabé's tragedy Θεοδώρα (Leipzig, 1884), and M. Sardou's play *Theodora*, produced in Paris in 1884. See also Dr F. Dahn's *Prokopios von Cäsarea* (1865), and, in addition, the works cited under Justinian. (J. Br.)

THEODORA, wife of the Roman emperor Theophilus. In the last year of her husband's reign (842) she overrode his ecclesiastical policy and summoned a council under the patriarch Methodius, in which the worship of images was finally restored and the iconoclastic clergy dispossessed. Appointed guardian of her infant son, Michael III., she carried on the government with a firm and judicious hand; she replenished the treasury and deterred the Bulgarians from an attempt at invasion. In order to perpetuate her power she purposely neglected her son's education, and therefore must be held responsible for the voluptuous character which he developed under the influence of his uncle Bardas. Theodora endeavoured in vain to combat Bardas's authority; in 855 she was displaced from her regency at his prompting, and being subsequently convicted of intrigues against him was relegated to a monastery. She was sainted in recompense for her zeal on behalf of image-worship.

THEODORA (d. 1057), daughter of the emperor Constantine VIII. Possessed of a strong and austere character, she refused the hand of the heir-presumptive, Romanus, who was married instead to her sister Zoë (1028). Though living in retirement she excited Zoë's jealousy, and on a pretext of conspiracy was confined in a monastery. In 1042 the popular movement which caused the dethronement of Michael V. also led to Theodora's instalment as joint-empress with her sister. After two months of active participation in government she allowed herself to be virtually superseded by Zoë's new husband, Constantine IX. Upon his death in 1054, in spite of her seventy years, she reasserted her dormant rights with vigour, and frustrated an attempt to supersede her on behalf of the general Nicephorus Bryennius. By her firm administration she controlled the unruly nobles and checked numerous abuses; but she marred her reputation by excessive severity towards private enemies and the undue employment of menials for advisers. She died suddenly in 1057.

See G. Finlay, *History of Greece*, vol. ii. (Oxford, 1877); G. Schlumberger, *L'Épopée Byzantine*, vol. iii. (Paris. 1905).

THEODORE, the name of two popes. Theodore I., pope from November 642 till May 649, succeeded John IV. He was the son of a bishop, and was born in Jerusalem. A zealous opponent of monothelitism, in the course of the protracted controversy he in a Roman synod excommunicated Pyrrhus, patriarch of Constantinople, and signed the document with ink mingled with consecrated wine. Theodore II. had a pontificate of only twenty days (Nov.–Dec. 897).

THEODORE (Rus. Fedor, or Feodor), the name of three tsars of Russia.

Theodore I. (1557–1598), tsar of Russia, the son of Ivan the Terrible and Anastasia Romanova, nominally succeeded his father in 1584, but being of weak intellect was governed throughout his reign by the boyar, Boris Godunov, whose sister Irene he married in 1580. On his death-bed he is said to have left the throne to his consort, with the Patriarch Job, Boris Godunov, and Theodore Romanov, afterwards the Patriarch Philaret, as her chief counsellors. Irene, however, retired into a monastery and her brother Boris stepped into her place.

See S. M. Solovev, *History of Russia* (Rus.), vol. viii. (Petersburg, 1895, &c.).

Theodore II. (1589–1605), tsar of Russia, was the son of Tsar Boris Godunov and one of the daughters of Malyuta-Skuratov, the infamous favourite of Ivan the Terrible. Passionately beloved by his father, he received the best available education for those days, and from childhood was initiated into all the *minutiae* of government, besides sitting regularly in the council and receiving the foreign envoys. He seems also to have been remarkably and precociously intelligent, and the first map of Russia by a native, still preserved, is by his hand. On the sudden death of Boris he was proclaimed tsar (13th of April 1605). Though his father had taken the precaution to surround him with powerful friends, he lived from the first moment of his reign in an atmosphere of treachery. On the 1st of July the envoys of Pseudo-Demetrius I. arrived at Moscow to demand his removal, and the letters which they read publicly in the Red Square decided his fate. On the 10th of July he was most foully murdered in his apartments in the Kreml.

See D. I. Ilovaisky, *The Anarchical Period in the Realm of Moscovy* (Rus.) (Moscow, 1894).

Theodore III. (1661–1682), tsar of Russia, was the eldest surviving son of Tsar Alexius and Maria Miloslavskaya. In 1676 he succeeded his father on the throne. He was endowed with a fine intellect and a noble disposition; he had received an excellent education at the hands of Simeon Polotsky, the most learned Slavonic monk of the day, knew Polish, and even possessed the unusual accomplishment of Latin; but, horribly disfigured and half paralyzed by a mysterious disease, supposed to be scurvy, he had been a hopeless invalid from the day of his birth. In 1679 he married his first cousin Agatha and assumed the sceptre. His native energy, though crippled, was not crushed by his terrible disabilities; and he soon showed that he was as thorough and devoted a reformer as a man incompetent to lead armies and obliged to issue his orders from his litter, or his bed-chamber, could possibly be. The atmosphere of the court ceased to be oppressive; the light of a new liberalism shone in the highest places; and the severity of the penal laws was considerably mitigated. He founded the academy of sciences in the Zaikonospassy monastery, where everything not expressly forbidden by the orthodox church, including Slavonic, Greek, Latin and Polish, was to be taught by competent professors. The chief difference between the

Theodorean and the later Petrine reforms was that while the former were primarily, though not exclusively, for the benefit of the church, the latter were primarily for the benefit of the state. The most notable reform of Theodore III., however, was the abolition, at the suggestion of Vasily Golitsuin, of *Myestnechestvo*, or "place priority," which had paralyzed the whole civil and military administration of Muscovy for generations (see GOLITSUIN). Henceforth all appointments to the civil and military services were to be determined by merit and the will of the sovereign. Theodore's consort, Agatha, shared his progressive views. She was the first to advocate beard-shearing. On her death (4th of July 1681) Theodore married Martha Apraksina. He died on the 27th of April 1682, without issue.

See M. P. Pogodin, *The First Seventeen Years of the Life of Peter the Great* (Rus.) (Moscow, 1875). (R. N. B.)

THEODORE (602–690), seventh archbishop of Canterbury, was born at Tarsus in Cilicia in 602. On the death of Wighard, who had been sent to Pope Vitalian by Ecgberht of Kent and Oswio of Northumbria in 667, apparently for consecration as archbishop, Theodore, who had become prominent in the Eastern work of the church, was recommended by Hadrian of Niridanum to fill the vacant see. Vitalian consecrated Theodore in April 688 on condition that Hadrian, afterwards abbot of St Peter's, Canterbury, should go with him. Hadrian was detained for some time by Ebroin, the Neustrian mayor of the palace, but Theodore reached England in May 669. According to Bede's account he made a tour of the whole of Anglo-Saxon England, reforming abuses and giving instruction as to the monastic rule and the canonical Easter. Bede also declares that he was the first archbishop to whom all the "church of the Angles" submitted. From the first he seems to have ignored the scheme for a separate province of York, but he reorganized the episcopate, assigning Bisi to East Anglia, Putta to Rochester, Hlothhere to Wessex, and Ceadda after reconsecration to Mercia. He brought the monastic education up to date by introducing literary, metrical and musical studies. In 673 Theodore presided at the first synod of the clergy in England which was held at Hertford. Various disciplinary regulations were emphasized, and an annual meeting arranged at a place called Cloveshoe. After this council Theodore revived the East Saxon bishopric, to which he appointed Earconwald. Soon after the first expulsion of Wilfrid in 678 he divided the Northumbrian diocese, appointing Trumwine bishop to the Picts. This led to a quarrel with Wilfrid which was not finally settled until 686–687. In 679 Theodore intervened to make peace between Ecgfrith of Northumbria and Aethelred of Mercia. He presided at other synods held in 680 at Hatfield and in 684 at Twyford, and died in 690. A penitential composed under Theodore's direction is still extant.

See Bede, *Hist. Eccl.*, edited by C. Plummer (Oxford, 1896); Eddius, *Vita Wilfridii* in J. Raine's *Historians of the Church of York*, vol. i. (London, 1879); *Anglo-Saxon Chronicle*, edited by Earle and Plummer (Oxford, 1899); Haddan and Stubbs, *Councils and Ecclesiastical Documents* (Oxford, 1869–78), iii. 173–213.

THEODORE LASCARIS (d. 1222), emperor of Nicaea, was born of a noble Byzantine family. He became the son-in-law of the Emperor Alexius III. and distinguished himself during the sieges of Constantinople by the Latins (1203–4). After the capture of the city he gathered a band of fugitives in Bithynia and established himself in the town of Nicaea, which became the chief rallying-point for his countrymen. Relieved of the danger of invasion by a Latin force which had defeated him in 1204 but was recalled to Europe by a Bulgarian invasion, he set to work to form a new Byzantine state in Asia Minor, and in 1206 assumed the title of emperor. During the next years Theodore was beset by enemies on divers sides. He maintained himself stubbornly in defensive campaigns against the Latin emperor Henry, defeated his rival Alexius Comnenus of Trebizond, and carried out a successful counter-attack upon Gayath-ed-din, the sultan of Koniah, who had been instigated to war by the deposed Alexius III. Theodore's crowning victory was gained in 1210, when in a battle near Pisidian Antioch he captured Alexius and wrested the town itself from the Turks. At the end of his reign he ruled over a territory roughly conterminous with the old Roman provinces of Asia and Bithynia. Though there is no proof of higher qualities of statesmanship in him, by his courage and military skill he enabled the Byzantine nation not merely to survive, but ultimately to beat back the Latin invasion.

See E. Gibbon, *The Decline and Fall of the Roman Empire*, vol. vi., ed. J. B. Bury (London, 1896); G. Finlay, *History of Greece*, vol. iii. (Oxford, 1877); and A. Meliarakes, Ἱστορία τοῦ Βασιλέιου τῆς Νικάιας καὶ τοῦ Δεσποτάτου τῆς Ἠπέιρου (Athens, 1898).

Theodore's grandson, THEODORE II. (Lascaris), emperor from 1254 to 1258, is chiefly noticeable for two brilliant campaigns by which he recovered Thrace from the Bulgarians (1255–56). His ill-health and early death prevented his making full use of his ability as a ruler.

See M. J. B. Pappadopoulos, *Théodore II. Lascaris, empereur de Nicée* (Paris, 1908).

IRENE LASCARIS, daughter of Theodore I. (Lascaris), was first married to the general Andronicus Palaeologus, and after his death became the wife of Theodore's successor, John Vatatzes (*q.v.*), and mother of Theodore II. She is much praised by historians for her modesty and prudence, and is said to have brought about by her example a considerable improvement in the morals of her nation. She died some ten years before her husband.

THEODORE OF MOPSUESTIA (*c.* 350–428), early Christian theologian, the most eminent representative of the so-called school of Antioch, was born at Antioch about the middle of the 4th century and was a friend of John Chrysostom; in rhetoric the celebrated Libanius was his teacher. Soon, however, he attached himself to the school of the great exegete and ascetic, Diodorus, a presbyter in Antioch, and with only a transitory period of vacillation, from which he was won back by Chrysostom, he remained faithful to the theology and ascetic discipline of this master. Under Diodorus he became a skilful exegete, and ultimately outstripped his master in biblical learning. About 383 Theodore became a presbyter in Antioch, and began to write against Eunomius the Arian and against the christology of Apollinaris. Soon after 392 he became bishop of Mopsuestia in Cilicia (the modern Missis near Adana). As such he was held in great respect, and took part in several synods, with a reputation for orthodoxy that was never questioned. It was greatly to his advantage that in the Eastern Church the period between the years 390 and 428 was one of comparative repose. He was on friendly terms even with Cyril of Alexandria. He died in 428 or 429, just at the beginning of the Nestorian controversy.

Theodore was a very prolific writer, but, before all, an exegete. He wrote commentaries on almost every book of the Old and New Testaments, of which, however, only a small proportion is now extant, as at a later period he lost credit in the church. We still possess in Greek his commentary on the Minor Prophets, in a Syriac version his commentary on St John,[1] and, in Latin translations, commentaries on the shorter Pauline epistles, besides very many fragments, especially on the epistle to the Romans. Theodore's importance as an exegete lies in two characteristics: (1) in opposition to the allegorical method he insists on getting at the literal meaning, and adheres to it when found; (2) in his interpretation of the Scriptures he takes into account the historical circumstances in which they were produced, and substitutes the historical-typological for the pneumatico-christological interpretation of prophecy; in other words, he interprets all Old Testament passages historically in the first instance, and sees the fulfilment of Old Testament prophecy in the history of Christ and His church only in so far as the entire Old Testament is a "shadow of things to come." Following his master Diodorus, who had already written a treatise Τίς διαφορὰ θεωρίας καὶ ἀλληγορίας, Theodore also was the author of a special dissertation against the allegorists, *i.e.* against Origen and his followers, which, however, has unfortunately perished. The comparative freedom of Theodore's view of inspiration is also noteworthy. He discriminates between historical, prophetical and didactic writings, and in accordance with this distinction assumes varying degrees of inspiration. Finally, he entertained very bold opinions about the canon and several of the books included in it.

[1] Ed. P. B. Chabot (Paris, 1897).

He esteemed very lightly the Solomonic writings and the book of Job; Canticles he explained as a nuptial poem of Solomon's; the book of Job appeared to him in many places hardly worthy of its subject, and he censures the writer sharply; Chronicles, Ezra and Nehemiah he entirely rejected; he denied the accuracy of the titles of the Psalms, anticipated the hypothesis that many of them belong to the Maccabean age, and referred the so-called Messianic element almost invariably to the kings of Israel; he even criticized the Catholic epistles and rejected the epistle of James. Characteristics such as these bring Theodore, of all patristic writers, nearest to the modern spirit. His commentaries contain a great deal of learned matter, and his grammatico-historical observations are still to some extent useful. But, on the other hand, his learning must not be overestimated. It falls behind that of Origen, Eusebius and Jerome, notwithstanding the superiority of his method It is specially noticeable that Theodore troubled himself little about textual criticism. He simply accepts the text of the LXX as that or revelation, and never manifests the slightest effort to control it by the original or even by the Syriac. He is a prosaic and often monotonous writer, and has other faults, *e.g* a lack of insight into the deeper movements of scriptural thought, and a want of spiritual and devotional fervour.

In addition to his commentaries Theodore also wrote extensive dogmatico-polemical works, which were destined to operate long after his death disastrously for his fame. As a disciple of Diodorus, Theodore accepted the Nicene teaching on the doctrine of the Trinity, but at the same time in christology took up a position very closely approaching that of Paul of Samosata. The violence of his opposition to his fellow-countryman, Apollinaris of Laodicea, perhaps the most acute and far-seeing theologian of the century, made it necessary for Theodore to formulate his christology with precision (in fifteen books on the Incarnation—all lost except a few fragments—and in special treatises against Apollinaris). He starts with a theory of man's relation to the world. Man is the *vinculum* of the cosmos, uniting in his person the material and the spiritual. This bond, broken by sin, was restored by Christ. According to Theodore the Logos assumed a complete manhood, which had to pass through the stages of ethical development just as in the case of any other human being. In this the Logos only supported the man Christ Jesus, but was not essentially connected with him; the Logos dwelt in him (ἐνοικεῖν), but any such thing as ἕνωσις φυσική did not and could not exist, because the finite is not "capax infiniti," and because any ἕνωσις would have destroyed the reality of the human nature. The same sober and thoughtful way of looking at things, and the same tendency to give prominence to the moral element, which characterize the commentaries of Theodore, appear also in his dogmatic. When, accordingly, the Nestorian controversy broke out, his works also were dragged into the discussion. At Ephesus, indeed, the memory of Theodore does not appear to have been attacked,[1] but soon afterwards the assault began. Marius Mercator, Rabbula of Edessa, Cyril, and other monophysites brought the charge of heresy against his writings, and sought to counteract their influence. But it was not until more than a century afterwards that his fanatical adversaries succeeded—in spite of the strong opposition of the best theologians of the West—in obtaining from Justinian the condemnation of his works in the controversy of the Three Chapters; this act of the emperor was confirmed by the fifth oecumenical council, and Theodore's name was accordingly deleted from the list of orthodox writers. From that day Theodore's works ceased to be read within the Byzantine Church, and hence have been lost. The Syrians, on the other hand, have always held in high esteem the memory of the great teacher, and have even carried back their liturgy to his name. The Nestorians, who called him "the Interpreter," possess, or possessed, a very large number of writings by him in Syriac translations.[2]

Theodore took part also in the Pelagian controversy at the time when it raged in Palestine. In the treatise, only partially preserved,[3] Πρὸς τοὺς λέγοντας φύσει καὶ οὐ γνώμῃ πταίειν τοὺς ἀνθρώπους, he sharply controverts the doctrine of original sin and Jerome its advocate. In his view the theory of Augustine is "a new heresy," a "malady"; he regarded it as a doctrine which necessarily led to dualism and Manichaeism. The attitude thus taken by Theodore is not surprising; he more nearly takes up the ground of the old church doctrine as set forth in the apologists and in the great Greek fathers of the 3rd and 4th centuries. The Pelagians driven from the East were received by him in Cilicia.

A brother of Theodore, Polychronius by name, bishop of Apamea in Syria (d. 430) also achieved high fame as an exegete, and expounded the theology of the school of Antioch.[4]

LITERATURE.—Migne, *Patrol.*, ser. Gr., lxvi. The Greek fragments of Theodore's New Testament commentaries have been collected by O. Fr Fritzsche (*Theod. Mops. in N.T. Comm.*, Turin, 1847). The commentaries on the Pauline epistles (Pitra, *Spicilegium Solesmense*, Paris, 1852, i. 49 seq.) have been edited by H. B. Swete (*Theod. Mops. in Epp. B. Pauli Comm.*, i., ii., Cambridge, 1880–82), along with the Greek fragments and the fragments of the dogmatical writings; on this edition, see E. Schürer, *Theol. Lit. Ztg.*, 1880–82. The commentary on the Minor Prophets will be found in Mai's *Nov. Patr. Biblioth.*, vii. 1854 (Berlin, 1834; Mai, *Script. Vet. Nov. Coll.*, vi., 1832). See also E. Sachau, *Theod. Mops. Fragm. Syriaca* (Leipzig, 1869); Fr. Bäthgen, "Der Psalmencommentar des Theod. v. Mops. in Syr. Bearbeitung," in *Ztschr. f. Alt-Test. Wissensch.*, v. 53 seq., vi. 261–288, vii. 1–60; and H. Lietzmann in *Sitzungsberichte der Kgl. preuss. Akad. der Wissensch. zu Berlin*, 1902, pp. 334 seq. Extracts from the writings of Theodore occur in the *Catenae* of Marius Mercator, in the *Acta* of the third and fifth oecumenical councils in Facundus, Liberatus, and Theodore's chief adversary Leontius Byzantinus. E. von Dobschütz, in *Amer. Journ. of Theol.*, ii. 353–387, published the Greek prologue of a commentary on *Acts* that is probably the work of Theodore.

The principal monograph on Theodore, apart from the prolegomena of Swete, and the same writer's article in *Dict. Christian Biog.*, iv. (1887), is that of H. Kihn (*Th. v. Mops. u. Junilius Afric. als Exegeten*, Freiburg, 1880). On his importance for the history of dogma see the works of Baur, Dorner, Harnack, Loofs and Seeberg. Literary and biographical details will be found in O. Fr. Fritzsche, *De Theod. Mops. Vita et Scriptis* (Halle, 1836); Fr. A. Specht, *Theod. v. Mops. u. Theodoret* (Munich, 1871); H. Kihn in the *Tüb. Quartalschr.*, 1879; E. Nestle in *Theol. Stud. aus Würtemb.*, ii. 210 seq.; P. Batiffol, "Sur une Traduction Latine de Th. de Mops.," in *Ann. de Philos. Chrét.*, 1885; Th. Zahn, "Das N. T. Theodors von Mop.," in *Neue Kirchl. Zeitschr.*, xi. 788–806; W. Wright, *Syriac Literature* (London, 1894); R. Duval, *La littérature syriaque* (Paris, 1899). (A. HA.)

THEODORET, bishop of Cyrrhus, an important writer in the domains of exegesis, dogmatic theology, church history and ascetic theology, was born in Antioch, Syria, about 386. At an early age he entered the cloister; and in 423 he became bishop of Cyrrhus, a small city in a wild district between Antioch and the Euphrates, where, except for a short period of exile, he spent the remainder of his life. The date of his death is uncertain, but it must have been at least six or seven years later than the council of Chalcedon (451). Although thoroughly devoted to the ideals of monasticism, he discharged his episcopal duties with remarkable zeal and fidelity. He was diligent in the cure of souls, labouring hard and successfully for the conversion of the numerous Gnostic communities and other heretical sects which still maintained a footing within the diocese. He himself claims to have brought more than a thousand Marcionites within the pale of the church, and to have destroyed many copies of the *Diatessaron* of Tatian, which were still in ecclesiastical use; and he also exerted himself to improve the diocese, which was at once large and poor, by building bridges and aqueducts, beautifying the town, and by similar works.

As an exegete Theodoret belongs to the Antiochene school, of which Diodorus of Tarsus and Theodore of Mopsuestia were the heads. He was not actually the personal disciple of either, but he adopted their methods, though without the consistency and boldness of the first-named. His extant commentaries (those on Canticles, on the Prophets, on the book of Psalms and on the Pauline epistles—the last the most valuable) are among the best performances of the fathers of the church. They are brief, yet not wanting in that element of practical edification on which Chrysostom lays special weight as characteristic of the Antiochenes. In addition to these complete commentaries, we have fragments of some others (of that on Isaiah, for example), principally met with in catenae. There are also special elucidations of some difficult Scripture texts.

Theodoret's chief importance is as a dogmatic theologian, it having fallen to his lot to take part in the Nestorian controversy and to be the most considerable opponent of the views of Cyril and Dioscurus of Alexandria. For more than twenty years he maintained the struggle against the Alexandrian dogmatic and its formulae (θεοτόκος, ἕνωσις καθ' ὑπόστασιν, μία ὑπόστασις, ἕνωσις φυσική, and the like), and taught that in the person of Christ we must strictly distinguish two natures (*hypostases*), which are united indeed in one person (*prosopon*), but are not amalgamated in essence. For these years his history coincides with that of the Eastern Church from 430 to 451, and for this very reason it is impossible to sketch it even briefly here (see Hefele, *Conc.-gesch.*, vol. ii.). The issue was not unfavourable to Theodoret's cause, but melancholy enough for Theodoret himself: the council of Chalcedon condemned monophysitism, but he unhappily yielded to pressure so far as also to take part in pronouncing "anathema upon Nestorius, and upon all who call not the Holy Virgin Mother of God, and who divide the one Son into two." As Theodoret had previously been a constant defender of Nestorius it was impossible for him to concur in this sentence upon his unfortunate friend with a clear conscience, and in point of fact he did not change his own dogmatic position. It is painful, therefore, to find him in his subsequent *Epitome* classing Nestorius as a heretic, and speaking of him with the utmost hostility. Some of Theodoret's dogmatic works are no longer extant: of his five books Περὶ ἐνανθρωπήσεως, for example, directed against Cyril after the council of Ephesus, we now possess fragments merely. A good deal of what passes under his name has been wrongly attributed to him. Certainly genuine are the refutation (Ἀνατροπή) of Cyril's twelve ἀναθεματισμοί of Nestorius, and the Ἐρανίστης, or Πολύμορφος, (written about 446), consisting of three dialogues, entitled respectively Ἄτρεπτος, Ἀσύγχυτος, and Ἀπαθής, in which the monophysitism of Cyril is opposed, and its Apollinarian character insisted on. Among the apologetico-dogmatic works of Theodoret must be reckoned his ten discourses Περὶ προνοίας.

Theodoret gives a valuable exposition of his own dogmatic in the fifth book of his Αἱρετικῆς κακομυθίας ἐπιτομή, already referred to.[1] This, the latest of his works in the domain of church history (it was written after 451), is a source of great though not of primary importance for the history of the old heresies. In spite of the investigations of Volkmar and Hilgenfeld, we are still somewhat in the dark as to the authorities he used. The chief uncertainty is as to whether he knew Justin's *Syntagma*, and also as to whether he had access to the *Philosophumena* of Hippolytus in their complete form. Besides this work Theodoret has also left us a church history in five books, from 324 to 429, which was published shortly before the council of Chalcedon. The style is better than that of Socrates and Sozomen, as Photius has remarked, but as a contribution to history the work is inferior in importance. Its author made use of Eusebius's *Life of Constantine*, and of the histories of Rufinus, Socrates and Sozomen, and probably of Philostorgius as well. He also used other sources, and made a thorough study of the writings of Athanasius, but apart from some documents he has preserved, relating to the Arian controversy, he does not contribute much that is not to be met with in Socrates. As regards chronology he is not very trustworthy; on the other hand, his moderation towards opponents, not excepting Cyril, deserves recognition. The Ἑλληνικῶν θεραπευτικὴ παθημάτων (*De Curandis Graecorum Affectionibus*)—written before 438—is of an historical and apologetic character, very largely indebted to Clement of Alexandria and Eusebius; it aims at showing the advantages of Christianity as compared with "the moribund but still militant" Hellenism of the day, and deals with the assaults of pagan adversaries. The superiority of the Christian faith both philosophically and ethically is set forth, the chief stress being laid on monachism, with which heathen philosophy has nothing to compare. Much prominence is also given to the cult of saints and martyrs.

On this side of his character, however, Theodoret can best be studied in the thirty ascetic biographies of his Φιλόθεος ἱστορία. This collection, which has been widely read, is a pendant to the *Historia Lausiaca* of Palladius and the monkish tales of Sozomen. For the East it has had the same importance as the similar writings of Jerome, Sulpicius Severus and Cassian for the West. It shows that the "sobriety" of the Antiochene scholars can be predicated only of their exegesis; their style of piety was as exaggerated in its devotion to the ideals of monasticism as was that of their monophysite opponents. Indeed, one of the oldest leaders of the school, Diodorus of Tarsus, was himself among the strictest ascetics.

181 letters of Theodoret have come down to us, partly in a separate collection, partly in the *Acta* of the councils, and partly in the Latin of Marius Mercator; they are of great value not only for the biography of the writer, but also for the history of his diocese and of the church in general.

The edition of Sirmond (Paris, 1642) was afterwards completed by Garnier (1684), who has also written dissertations on the author's works. Schulze and Nösselt published a new edition (6 vols., Halle, 1769–74) based on that of their predecessors; a glossary was afterwards added by Bauer. The reprint will be found in vols. lxxx.–lxxxiv. of Migne, and considerable portions occur in Mansi. The church history has been published frequently in connexion with the histories of Socrates, Sozomen and others, *e.g.* by Valesius (1693) and Reading (1720). There is an English translation of the history by Bloomfield Jackson in the *Nicene and Post-Nicene Fathers*, series ii., vol. iii.; the translation including also the dialogues and letters.

Besides the earlier labours of Tillemont, Ceillier, Oudin, Du Pin and Fabricius and Harless, see Schröckh, *Kirchengesch.*, vol. xviii.; Hefele, *Conc.-gesch.*, vol. ii.; Richter, *De Theodoreto Epp. Paul. Interprete* (Leipzig, 1822); Binder, *Études sur Théodoret* (Geneva, 1844); Stäudlin, *Gesch. u. Lit. der Kirchengesch.* (Hanover, 1827); Kihn, *Die Bedeutung der antioch. Schule* (1866); Diestel, *Das A. T. in der christl. Kirche* (Jena, 1869); Specht, *Theodor v. Mopsvestia u. Theodoret v. Cyrus* (Munich, 1871); Roos, *De Theodoreto Clementis et Eusebii Compilatore* (Halle, 1883); Nolte in the *Tübing. Quartalschr.* (1859), p. 302 seq.; Möller, art. "Theodoret," in Herzog-Hauck's *Realencykl.*; Venables's article in Smith and Wace's *Dict. of Christian Biography*; also Bardenhewer's *Patrologie*, p. 345 ff. On the sources of Theodoret's church history see Jeep, *Quellenuntersuchungen z. d. Griech. Kirchenhistorikern* (Leipzig, 1884); and especially Güldenpenning, *Die Kirchengesch. des Theodoret von Kyrrhos* (Halle, 1889). (A. Ha.; A. C. McG.)

[1] Roman Catholic writers vary greatly in their estimate of Theodoret's christology and of his general orthodoxy. On Bertram's essay on this subject (*Theodoreti, Episcopi Cyrensis, Doctrina Christologica*, Hildesheim, 1883), see *Theol. Lit.-Ztung.* (1883), 563 seq.

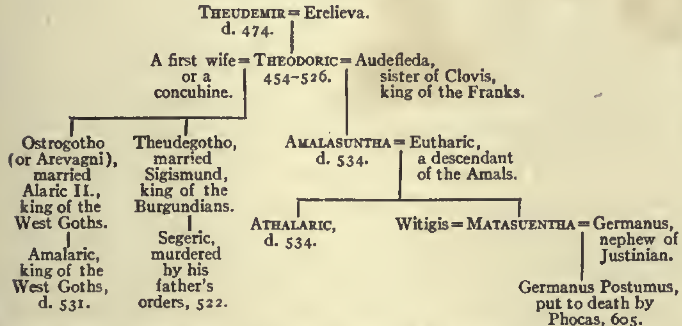
THEODORIC, king of the Ostrogoths (*c.* 454–526). Referring to the article Goths for a general statement of the position of this, the greatest ruler that the Gothic nation produced, we add here some details of a more personal kind. Theodoric was born about the year 454, and was the son of Theudemir, one of three brothers who reigned over the East Goths, at that time settled in Pannonia. The day of his birth coincided with the arrival of the news of a victory of his uncle Walamir over the sons of Attila. The name of Theodoric's mother was Erelieva, and she is called the concubine of Theudemir. The Byzantine historians generally call him son of Walamir, apparently because the latter was the best known member of the royal fraternity. At the age of seven he was sent as a hostage to the court of Constantinople, and there spent ten years of his life, which doubtless exercised a most important influence on his subsequent career. Soon after his return to his father (about 471) he secretly, with a *comitatus* of 10,000 men, attacked the king of the Sarmatians, and wrested from him the important city of Singidunum (Belgrade). In 473 Theudemir, now chief king of the Ostrogoths, invaded Moesia and Macedonia, and obtained a permanent settlement for his people near Thessalonica. Theodoric took the chief part in this expedition, the result of which was to remove the Ostrogoths from the now barbarous Pannonia, and to settle them as *foederati* in the heart of the empire. About 474 Theudemir died, and for the fourteen following years Theodoric was chiefly engaged in a series of profitless wars, or rather plundering expeditions, partly against the emperor Zeno, but partly against a rival Gothic chieftain, another Theodoric, son of Triarius.[2] In 488 he set out at the head of his people to win Italy from Odoacer. There is no doubt that he had for this enterprise the sanction of the emperor, only too anxious to be rid of so troublesome a guest. But the precise nature of the relation which was to unite the two powers in the event of Theodoric's success was, perhaps purposely, left vague. Theodoric's complete practical independence, combined with a great show of deference for the empire, reminds us somewhat of the relation of the old East India Company to the Mogul dynasty at Delhi, but the Ostrogoth was sometimes actually at war with his imperial friend. The invasion and conquest of Italy occupied more than four years (488–493). Theodoric, who marched round the head of the Venetian Gulf, had to fight a fierce battle with the Gepidae, probably in the valley of the Save. At the Sontius (Isonzo) he found his passage barred by Odoacer, over whom he gained a complete victory (28th of August 489). A yet more decisive victory followed on the 30th September at Verona. Odoacer fled to Ravenna, and it seemed as if the conquest of Italy was complete. It was delayed, however, for three years by the treachery of Tufa, an officer who had deserted from the service of Odoacer, and of Frederic the Rugian, one of the companions of Theodoric, as well as by the intervention of the Burgundians on behalf of Odoacer. A sally was made from Ravenna by the besieged king, who was defeated in a bloody battle in the Pine Wood. At length (26th of February 493) the long and severe blockade of Ravenna was ended by a capitulation, the terms of which Theodoric disgracefully violated by slaying Odoacer with his own hand (15th of March 493). (See Odoacer.)

The thirty-three years' reign of Theodoric was a time of unexampled happiness for Italy. Unbroken peace reigned within her borders (with the exception of a trifling raid made by Byzantine corsairs on the coast of Apulia in 508). The

[2] In one of the intervals of friendship with the emperor in 483 Theodoric was made master of the household troops and in 484 consul.

venality of the Roman officials and the turbulence of the Gothic nobles were sternly repressed. Marshes were drained, harbours formed, the burden of the taxes lightened, and the state of agriculture so much improved that Italy, from a corn-importing, became a corn-exporting country. Moreover Theodoric, though adhering to the Arian creed of his forefathers, was during the greater part of his reign so conspicuously impartial in religious matters that a legend which afterwards became current represented him as actually putting to death a Catholic deacon who had turned Arian in order to win his favour. At the time of the contested papal election between Symmachus and Laurentius (496–502), Theodoric's mediation was welcomed by both contending parties. Unfortunately, at the very close of his reign (524), the Emperor Justin's persecution of the Arians led him into a policy of reprisals. He forced Pope John to undertake a mission to Constantinople to plead for toleration, and on his return threw him into prison, where he died. Above all, he sullied his fame by the execution of Boetius and Symmachus (see BOETIUS). It should be observed, however, that the motive for these acts of violence was probably political rather than religious—jealousy of intrigues with the imperial court rather than zeal on behalf of the Arian confession. Theodoric's death, which is said to have been hastened by remorse for the execution of Symmachus, occurred on the 30th of August 526. He was buried in the mausoleum which is still one of the marvels of Ravenna (*q.v.*), and his grandson Athalaric, a boy of ten years, succeeded him, under the regency of his mother Amalasuntha.

Genealogy of Theodoric.



Amalafrida, a full sister of Theodoric, married Thrasamund, king of the Vandals, and was mother, by an earlier marriage, of Theodahad (d. 536).

AUTHORITIES.—The authorities for the life of Theodoric are very imperfect. Jordanes, Procopius, and the curious fragment known as Anonymus Valesii (printed at the end of Ammianus Marcellinus) are the chief direct sources of narrative, but far the most important indirect source is the *Variae* (state-papers) of Cassiodorus, chief minister of Theodoric. Malchus furnishes some interesting particulars as to his early life, and it is possible to extract a little information from the turgid panegyric of Ennodius. Among German scholars F. Dahn (*Könige der Germanen*, ii., iii. and iv.), J. K. F. Manso (*Geschichte des Ostgothischen Reichs in Italien*, 1824), and Sartorius (*Versuch über die Regierung der Ostgothen*, &c.) have done most to illustrate Theodoric's principles of government. The English reader may consult Gibbon's *Decline and Fall*, chap. xxxix., and Hodgkin's *Italy and her Invaders*, vol. iii. (1885), his introduction to *Letters of Cassiodorus* (1886) and *Theodoric the Goth* (London and New York, 1891). For the legends connected with the name of Theodoric see the article DIETRICH OF BERN.

(T. H.)

THEODORUS, FLAVIUS MALLIUS, Roman consul A.D. 399, author of an extant treatise on metres, one of the best of its kind (H. Keil, *Grammatici Latini*, vi.). He also studied philosophy, astronomy and geometry, and wrote works on those subjects, which, together with his consulship, formed the subject of a panegyric by Claudian.

THEODORUS STUDITA (A.D. 759–826), Greek theological writer, abbot of the monastery of Studium, was born at Constantinople. In 794 he succeeded his uncle Plato, who had persuaded him to become a monk some ten years before, as head of the monastery of Saccudium in Bithynia. Soon afterwards he was banished to Thessalonica for having excommunicated Constantine VI., who had divorced his wife Maria in order to marry Theodotē. After the emperor's death in 797 he was recalled with every mark of favour, and removed with his monks to the monastery of Studium in Constantinople, where he carried on a vigorous campaign in favour of asceticism and monastic reform. In 809 he was again banished in consequence of his refusal to hold communion with the patriarch Nicephorus, who had pardoned the priest Joseph for his part in the marriage of Constantine and Theodotē. In 811 he was recalled by Michael Rhangabes, and again banished in 814 for his resistance to the edict of Leo the Armenian, which forbade the worship of images. Liberated in 821 by the Emperor Michael the Stammerer (Balbus), he soon got into trouble again. In 824 he violently attacked Michael for showing too great leniency towards the iconoclasts and even favoured an insurrection against him. When the attempt failed, Theodorus found it prudent to leave Constantinople. He lived at various monasteries in Bithynia, on Chalcitis (one of the Princes' Islands) and on the peninsula of Tryphon, near the promontory of Acrita, where he died on the 11th of November 826. He was buried at Chalcitis, but his body was afterwards (26th of January 844) removed to Studium. He subsequently received the honours of canonization. Of his extant works the following are the most important:—*Letters*, which are of considerable value as giving an insight into the life and character of the writer, and throwing light upon the ecclesiastical disputes in which he was involved; *Catecheses* (divided into *Magna* and *Parva*), two collections of addresses to his monks on various subjects connected with the spiritual life; funeral orations on his mother and his uncle Plato; various polemical discourses connected with the question of image-worship. He was also the author of epigrams on various subjects, which show considerable originality, and of some church hymns. Like all the monks of Studium, Theodore was famous for his calligraphy and industry in copying MSS.

BIBLIOGRAPHY.—General edition of his works in J. P. Migne, *Patrologia Graeca*, xcix., to be supplemented (for the *Letters*) by A. Mai's *Patrum Nova Bibliotheca*, viii. (1871) and (for the *Catecheses*) by *ib.*, ix. (1888), which contains the Greek text of the *Parva* (also ed. separately by E. Auvray, 1891); hymns in J. B. Pitra, *Analecta Sacra*, i. (1876). See also Alice Gardner, *Theodore of Studium: his Life and Times* (1905), containing specimens of English translation and an account of his published works; C. Thomas, *Theodor von Studion und sein Zeitalter* (1892); G. A. Schneider, *Theodor von Studion*, in "Kirchengeschichtliche Studien," v. 3 (Münster, 1900); S. Schiwietz, *De Sancto Theodoro Studita* (Breslau, 1896); E. Marin, *De Studio coenobio Constantinopolitano* (1897); C. Schwarzlose, *Der Bilderstreit* (1890); A. Tougard, *La Persécution iconoclaste d'après la correspondance de saint Théodore Studite* (1891). Some of the hymns have been translated by J. M. Neale in his *Hymns of the Eastern Church*. For further bibliographical details see C. Krumbacher, *Gesch. der byz. Litt.* (2nd ed., 1897) and article by Von Dobschütz in Herzog-Hauck's *Realencyclopädie für protestantische Theologie*, xix. (1907). On his relation to Theophanes Confessor (*q.v.*), see J. Pargoire, "Saint Théophane le Chronographe et ses rapports avec saint Théodore Studite" in Βυζαντινὰ Χρονικά, ix. (St Petersburg, 1902).

THEODOSIA, formerly KAFFA, a seaport and watering-place of South Russia, on the east coast of the Crimea, 66 m. E.N.E. of Simferopol and 72 m. by a branch line from the Sebastopol-Ekaterinoslav railway. It has an excellent modern harbour, and its roadstead, which is never frozen, is well protected from east and west winds, and partly also from the south, but its depth is only 11 to 14 ft., reaching 35 ft. in the middle. The population was 10,800 in 1881, and 27,236 in 1897. Among the motley population of Russians, Tatars, Armenians, Germans and Greeks are several hundred Qaraite Jews. Few remains of its former importance exist, the chief being the Citadel built by the Genoese and still showing Latin inscriptions on some of its towers, the one or two detached towers left when the town walls were pulled down, and two or three mosques, formerly Genoese churches. The town also possesses a museum of antiquities and a picture gallery containing the works of the marine painter Ayvazovsky. Theodosia is an episcopal see of the Orthodox Greek Church. Gardening is one of the leading industries; fishing, a few manufactures, and agriculture are carried on. Theodosia has gained much of the trade of Sevastopol since that town was made a military port in 1894, and the value of its exports (1½–2½ millions sterling annually), principally grain and oil-seeds, is increasing year by year. A bronze statue of Alexander III. was put up on the sea-front in 1896.

The ancient Theodosia, the native name of which was Ardabda, was a colony founded from Miletus. Archaic terra-cottas show it to have been inhabited in the 6th century B.C., but it is first heard of in history as resisting the attacks of Satyrus, ruler of the Cimmerian Bosporus, *c.* 390 B.C. His successor Leucon took it and made it a great port for shipping wheat to Greece, especially to Athens. This export of wheat continued until the days of Mithradates VI. of Pontus, against whom the city revolted. Later it became a special part of the Bosporan kingdom with its own governor. In the 3rd century A.D. it was still inhabited, but seems to have been deserted not long afterwards. Besides the terra-cottas and pottery very beautiful Greek jewelry has been found near Theodosia. It coined silver and copper during the 5th and 4th centuries B.C. The name Kaffa (Genoese *Capha*, Turkish *Kefe*) first occurs in a writer of the 9th century. The Genoese established themselves on the site shortly after 1266, and the settlement flourished exceedingly, being the depôt of a trade route reaching to China. It became the head of the Genoese establishments in Gazaria, the see of a bishop, and the chief port on the northern shore of the Black Sea, far surpassing the Venetian Tana. Its population is said to have reached 80,000 souls of many creeds and nationalities. There was a citadel (still remaining) and magnificent walls. These were rendered necessary by the occasional hostility of the Tatar khans. When the Turks took Constantinople the colony was almost cut off from the mother city, which handed it over to the enterprising bank of St George; but it could not be saved and fell in 1475 to the Turks, who sometimes called it Kuchuk-Stambul (Little Stambul or Constantinople) or Krym-Stambul (Stambul of Crimea). Its new masters kept it under their own direct rule and its prosperity was not entirely destroyed. In 1771 it was taken by the Russians, and in 1783 annexed by them, whereupon the greater part of its population deserted it. Its prosperity did not return until about 1894, when new harbour works made it a convenient port for grain ships coming light out of the Sea of Azov and wishing to complete their cargoes.

See E. von Stern, *Theodosia* (German and Russian, Odessa, 1906); E. H. Minns, *Scythians and Greeks* (Cambridge, 1909); for the history of Kaffa see Heyd, *Histoire du commerce du Levant au moyen âge* (Paris, 1886), vol. ii. (E. H. M.)

THEODOSIUS, the name of three Roman emperors of the East.

THEODOSIUS I., "the Great," son of Theodosius, Valentinian's great general, who in 368–69 drove back the Picts and Scots from the Roman territories in Britain and suppressed the revolt of Firmus in Mauretania (372). Shortly after (376), the elder Theodosius was put to death by order of Valens, probably through fear lest he should be the Theodosius or Theodore whom a magician had indicated as the future emperor. The younger Theodosius was born about the year 346. He was a native of Spain, but the exact place of his birth is uncertain (Cauca in Galicia according to Idatius and Zosimus, Italica according to Marcellinus). He accompanied his father into Britain (368), and a little later distinguished himself by defeating the Sarmatians who had invaded Moesia (374). On his father's death he retired to his native place, where he lived quietly till after the great battle of Adrianople (August 9, 378), when Gratian summoned him to share the empire. After gaining some fresh victories over the Sarmatians, Theodosius was made Augustus at Sirmium on the 19th of January 379, and was assigned all the eastern provinces, including part of Illyricum. It was a time of great peril for the Roman state. While the Visigoths were carrying their raids up to the walls of Constantinople, bands of Ostrogoths, Taifali, Huns and Alans joined them in overrunning the Balkan countries. In 379 Theodosius, after reorganizing the army at Thessalonica, carried on a successful campaign of skirmishes along the Danube and induced numerous Gothic bands to give in their allegiance; his lieutenant Modares, a Gothic refugee, defeated the invaders severely in Thrace. At the end of the year Theodosius went to Constantinople to be crowned. Returning to Thessalonica in 380 he was kept out of the field for some time by a serious illness. In this year or the next he was called upon to meet two armies of invaders. He conducted in person the war against the Visigoths under Fritigern (in Macedonia and Epirus), and on one occasion was nearly betrayed into the enemy's hands; this campaign, in which Gratian's general Arbogast eventually lent help, was ended by Fritigern's death. The defence of the Danube against the Ostrogoths under Alatheus and Safrax was entrusted to the general Promotus, who severely defeated the enemy in an attempt to cross the river. Theodosius attained even greater successes by his diplomacy. He persuaded the fugitive Visigoth king Athanaric to enter his service, and enlisted 40,000 of his former enemies as *foederati*, providing them with settlements in various parts of the realm. Though this kindness towards the Germanic tribes was resented by the Romans, and in some cases ill requited, yet it may be said that it not only averted a great danger to the empire, but considerably strengthened Theodosius' army. In 382 the pacification of the Balkans was complete. In 386 Promotus checked a new attempt at invasion on the Danube.

In 383 Theodosius created his eldest son Arcadius Augustus. The same year saw the revolt of Maximus in Britain and the murder of Gratian. For five years Theodosius consented to accept the usurper as his colleague; but when Maximus attempted a few years later to make himself master of Italy Theodosius advanced against the invader and overthrew him near Aquileia (July 28, 388). This victory was followed by the murder of Maximus and his son Victor, after whose death Theodosius conferred upon Valentinian II. all that part of the empire which his father had held. After celebrating a triumph in Rome (389) he stayed to arrange the government of Italy for another two years. If we may trust the evidence of Zosimus, from the end of the year 388 Theodosius resigned himself to gluttony and voluptuous living, from which he was only roused by the news that in the Western empire Arbogast had slain the young Emperor Valentinian and set up the grammarian Eugenius in his stead (May 15, 392).

Theodosius made extensive levies and with a force partly composed of barbarian auxiliaries marched out against Eugenius. The armies met near the river Frigidus, some thirty-six miles distant from Aquileia. On the first day Theodosius' barbarians, engaging with those of the hostile army, were almost destroyed, and the victory seemed to be with Eugenius. After a night of prayer, towards cockcrow the emperor was cheered by a vision of St Philip and St John, who, mounted on white steeds, promised him success. On the second day the issue was doubtful till, if we may trust the concurrent testimony of all the contemporary church historians, a sudden gust of wind blew back the enemy's arrows on themselves. This was the turning-point of the battle: Eugenius was slain by the soldiers; and two days later Arbogast committed suicide (September 5–9, 394). From the north-eastern parts of Italy Theodosius passed to Rome, where he had his son Honorius proclaimed emperor under the guardianship of Stilicho. Thence he retired to Milan, where he died of dropsy (January 17, 395), leaving the empire to be divided between his two sons Honorius and Arcadius.

Important as the reign of Theodosius was from the political point of view, it is perhaps still more so from the theological. According to Sozomen, his parents were both orthodox Christians, according to the creed sanctioned by the council of Nicaea. It was not, however, till his illness at Thessalonica that the emperor received baptism at the hands of Bishop Ascholius, whereupon, says the same historian, he issued a decree (February 380) in favour of the faith of St Peter and Pope Damasus of Rome. This was to be the true Catholic faith; the adherents of other creeds were to be reckoned as heretics and punished. The great council of

Constantinople, consisting of 150 orthodox and 36 Macedonian bishops, met in the following year, confirmed the Nicene faith, ordered the affairs of the various sees, and declared the bishop of Constantinople to rank next to the bishop of Rome. The emperor cannot be acquitted of the intolerance which marks edicts such as that depriving apostatizing Christians of the right of bequest. It was not till 389 or 390 that he issued orders for the destruction of the great image of Serapis at Alexandria. Other edicts of an earlier or later date forbade the unorthodox to hold assemblies in the towns, enjoined the surrender of all churches to the catholic bishops, and overthrew the heathen temples "throughout the whole world." During the reign of Theodosius Gregory of Nazianzus was made bishop of Constantinople. In 383 Theodosius called a new council for the discussion of the true faith. The orthodox, the Arians, the Eunomians and the Macedonians all sent champions to maintain their special tenets before the emperor, who finally decided in favour of the orthodox party. He seems to have suffered the Novatians to hold assemblies in the city. Perhaps the most remarkable incident in the life of Theodosius from a personal point of view is the incident of his submission to the reprimands of Ambrose, who dared to rebuke him and refuse to admit him to the Eucharist till he had done public penance for punishing a riot in Thessalonica by a wholesale massacre of the populace. Equally praiseworthy is the generous pardon that the emperor, after much intercession, granted to the seditious people of Antioch, who, out of anger at the growing imposts, had beaten down the imperial statues of their city (387). When the Christians in the eastern part of the empire destroyed a Jewish synagogue and a church belonging to the Valentinians, Theodosius gave orders for the offenders to make reparation. Such impartial conduct drew forth a remonstrance from Ambrose, who, where the interests of his creed were concerned, could forget the common principles of justice.

Theodosius was twice married—(1) to Aelia Flacilla, the mother of Arcadius (377–408) and Honorius (384–423); (2) to Galla (d. 394), the daughter of Valentinian I.

The chief authorities for the age of Theodosius are Ammianus Marcellinus, Zosimus, Eunapius and the ecclesiastical historians (Socrates, Sozomen, Theodoret). Much information may also be gleaned from the writings of St Ambrose, St Gregory of Nazianzus, Isidore of Seville, and the orators Pacatus, Libanius, Themistius. Among modern authorities see: E. Gibbon, *The Decline and Fall of the Roman Empire* (ed. Bury, London, 1896), chaps. 25 and 27; T. Hodgkin, *Italy and her Invaders* (Oxford, 1892), chaps. 5, 6, 8–11; A. Güldenpenning and J. Ifland, *Der Kaiser Theodosius der Grosse* (Halle, 1878); G. R. Sievers, *Studien zur Geschichte der römischen Kaiser* (Berlin, 1870), pp. 283–333.

Theodosius II. (401–450) succeeded his father Arcadius as emperor of the East in 408. During his minority the empire was ably ruled by the praetorian prefect Anthemius and Pulcheria, who became her brother's guardian in 414. Under his sister's care the young emperor was trained in divers accomplishments which won him the name of *Calligraphēs* ("the Penman"), but grew up into a weak though amiable character. Through his generals Ardoburius and Aspar he waged two fairly successful wars against the Persians (421 and 441), and after the failure of one expedition (431) by means of a gigantic fleet put an end to the piracies of the Vandal Genseric. A Hunnish invasion in 408 was skilfully repelled, but from 441 the Balkan country was repeatedly overrun by the armies of Attila, whose incursions Theodosius feebly attempted to buy off with ever-increasing payments of tribute. His internal administration, though not sufficiently rigorous to check abuses, was upright and thoughtful. Among its chief events may be mentioned the endowment of the university of Constantinople (425), the conciliatory council of Ephesus (434) and the publication of the *Codex Theodosianus* (438), a collection of imperial constitutions for the benefit of public officials, which is our chief source of information about the government of the empire in the 5th century. In 450 Theodosius died of injuries sustained through a fall from his horse.

See E. Gibbon, *The Decline and Fall of the Roman Empire* (ed. Bury, London, 1896), iii. pp. 381–444; A. Güldenpenning, *Geschichte des oströmischen Reiches unter den Kaisern Arkadius und Theodosius II.* (Halle, 1885), pp. 172 sqq.; T. Mommsen and P. Meyer, *Theodosii libri XVI*. (Berlin, 1904–5).

Theodosius III., emperor of the East (716–717), was a financial officer whom a Byzantine army rebelling against Anastasius III. unexpectedly proclaimed monarch in his stead. He captured Constantinople after a six months' siege and deposed Anastasius, but in the following year was himself forced to resign by a new usurper, Leo III. (*q.v.*). Theodosius ended his life in a monastery.

See G. Finlay, *History of Greece* (ed. 1877, Oxford), i. p. 396).

(M. O. B. C.)

THEODOSIUS OF TRIPOLIS, Greek geometer and astronomer, three of whose works were contained in the collection of lesser writings named ὁ μικρὸς ἀστρονομούμενος (sc. τόπος), or ὁ μικρὸς ἀστρονόμος.[1] Suīdas erroneously identifies him with a sceptical philosopher of the same name who lived in the second half of the 2nd century A.D. or later, but, on the other hand, distinguishes him from a native of Tripolis who wrote a poem on spring. He is doubtless the same as Theodosius the mathematician, who is mentioned by Strabo amongst the natives of Bithynia distinguished for their learning, and whose sons were also mathematicians, the same, too, as the inventor of a universal sun-dial (*horologium* πρὸς πᾶν κλίμα) of that name who is praised by Vitruvius (*De Architectura*, ix. 9). His date, therefore, could not have been later than the 1st century B.C.; he may, however, have lived in the preceding century, inasmuch as the names mentioned by Strabo in the passage referred to above are, as far as we know, arranged chronologically, and Theodosius immediately follows Hipparchus, who made astronomical observations between 161 and 126 B.C., and precedes Asclepiades the physician, who lived at Rome at the beginning of the 1st century B.C.

His chief work—σφαιρικά, in three books—is a tolerably complete treatise on the pure geometry of the surface of a sphere, and was still the classical book on the subject in Pappus's time. It does not contain (except for a faint suggestion in iii. 11–12) any trace of spherical trigonometry, which, on the other hand, was the special subject of the work having the same title, and included in the same collection, of Menelaus of Alexandria, who lived at the end of the 1st century.

A. Nokk (*Ueber die Sphärik des Theodosius*; Karlsruhe, 1847), Heiberg (*Litterargeschichtliche Studien über Euklid*, pp. 43 seq.; Leipzig, 1882), and Hultsch (*Jahrbücher für classische Philologie*, 1883, pp. 415–420, and *Autolycus*; Leipzig, 1885) have proved that as early as the middle of the 4th century B.C. there existed a Greek text-book on *Spherics* which, in its essential contents, scarcely deviated from the three books of Theodosius. He must therefore be regarded as merely the editor, or at most the elaborator and expounder, of a doctrine which existed some centuries before him. A careful analysis of Theodosius' work, from this point of view, will be found in A. A. Björnbo's *Studien über Menelaos Sphärik* (*Abhandlungen zur Geschichte der mathematischen Wissenschaften*, xiv.; Teubner, 1902).

The *Spherics* of Theodosius was translated into Arabic at the beginning of the 10th century, and from the Arabic into Latin in the 12th century by Plato of Tivoli (Tiburtinus) This translation was published in 1518 at Venice, but was found so faulty by J. Voegelinus that he published a new Latin version, together with additions from the Arabian commentators (Vienna, 1529, 4to); other Latin translations were published by F. Maurolycus (Messina, 1558, fol.); by C. Clavius (Rome, 1586, 4to); and by Barrow under the title, *Theodosii Sphaerica, Methodo Nova Illustrata et Succincte Demonstrata* (London, 1675, 4to). The Greek text was first published, and with it a Latin translation, by J. Pena (Paris, 1558, 4to); it has been edited since by Joseph Hunt (Oxford, 1707), and by E. Nizze (Berlin, 1852), but these two editions are founded on that of Pena. There is also a German translation by Nizze (Stralsund, 1826). His two editions are accompanied with valuable notes and an appendix containing additions from Voegelinus and others.

The two other works of Theodosius which have come down to us have not as yet been published in the original. The propositions, without demonstrations, in the work περὶ ἡμερῶν καὶ νυκτῶν (*On Days and Nights*), in two books, were given by Dasypodius, in Greek and Latin, in his *Sphaericae Doctrinae Propositiones* (Strasburg, 1572, 8vo). A Latin version of the complete work, with ancient *scholia* and figures, was given by Joseph Auria (Rome, 1591, 4to). Pappus has given a pretty full commentary on the

[1] This collection contained, according to Fabricius, *Bibliotheca Graeca*, ed. Harles, iv. p. 16, the following books:—"Theodosii Tripolitae, *Sphaericorum*, libri iii.; Euclidis, *Data, Optica, Catoptrica, ac Phaenomena*; Theodosii Tripolitae, *De Habitationibus* et *Noctibus ac Diebus*, libri ii.; Autolyci Pitanaei, *De Sphaera Mota*, et libri ii. *De Ortu atque Occasu Stellarum Inerrantium*; Aristarchi Samii, *De Magnitudinibus ac Distantiis Solis ac Lunae*; Hypsiclis Alexandrini, Ἀναφορικὸς sive *De Ascensionibus*; Menelai, *Sphaericorum*, libri iii." Euclid's *Data* is, however, wrongly included, for Pappus, vii., makes it part of analysis (ὁ ἀναλυόμενος τόπος).

first book of this work of Theodosius. His work περὶ οἰκήσεων (*On Habitations*) also was published by Auria (Rome, 1588). It gives an account of how, for every inhabitant of the earth from the equator to the pole, the starry firmament presents itself in the course of a year. The propositions in it were also given by Dasypodius in his work mentioned above. (T. L. H.)

THEODULF, bishop of Orleans, was born about the middle of the 8th century, of a noble family of Gothic extraction, probably in Spain. He found favour at the Frankish court, was made abbot of Fleury and of Saint-Aignan, and in 781 became bishop of Orleans. He was a staunch supporter of Charlemagne's principles of government and educational reforms; he established schools, and by his own literary achievements showed himself a worthy member of the learned circle which graced the Carolingian court. He was likewise a good churchman and an able administrator of his diocese; he encouraged the reformation of the clergy and the monasteries. In 798 he was appointed *missis dominicus*, and two years later performed so great services for Leo III. as judge in the cause between the pope and his enemies, that he returned from Rome with the pallium. After the death of Alcuin he became the foremost councillor to the king on theological matters: it was he who made, on Charlemagne's request, a collection of the opinions of the fathers on the much-disputed point of the procession of the Holy Ghost. Theodulf maintained his influence a short time after the death of Charlemagne, being sent as escort to Pope Stephen V. who came in 816 to crown Louis the Fair. Later, however, he was accused of having taken part in the conspiracy of Bernard of Italy, and in 818 was deposed from all his dignities and imprisoned in a monastery at Angers. Theodulf asserted his innocence to the end, and no proof of his guilt has come down to us; in fact, from what we know of the bishop's life and political principles we should presuppose his innocence. He died in prison, probably from poison, in 821.

Theodulf was called Pindar in the palace school of Charlemagne. Fond of Latin literature, whether Christian or pagan, and a friend of the arts, he was himself one of the best writers of the period. His prose works include sermons, treatises on vices and on baptism, a penitential, capitularies and exhortations to bishops, priests and judges. His poems are his best work, and afford us a vivid picture of the times. Theodulf was the author of at least part of the hymn for Palm Sunday, the *Gloria laus*. The complete works of Theodulf are in J. P. Migne, *Patrol. Lat.*, vol. 105 (Paris, 1851). The best edition of his poetry is that of E. Dümmler in the *Mon. Germ. Hist. Poetae latini aevi carolini*, vol. i. (Berlin, 1881).

See C. Cuissard, *Théodulphe évêque d'Orléans, sa vie et ses œuvres*, (Orleans, 1892); and a critical study of the writings by M. Manitius in *Neues Archiv der Ges. für ä. deutsche Gesch.* xi. (1886).

THEOGNIS OF MEGARA (6th century B.C.), Greek poet. More than half the elegiac poetry of Greece before the Alexandrian period is included in the 1400 lines ascribed to Theognis. This collection contains several poems acknowledged to have been composed by Tyrtaeus, Mimnermus and Solon; with two exceptions (T. W. Allen in *Classical Review*, Nov. 1905, and E. Harrison) modern critics unanimously regard these elegies as intruders, that is, not admitted into his works by Theognis himself; for this and other reasons they assume the existence of further interpolations which we can no longer safely detect. Generations of students have exhausted their ingenuity in vain efforts to sift the true from the false and to account for the origin and date of the Theognidea as we possess them; the question is fully discussed in the works of Harrison and Hudson-Williams.

The best-attested elegies are those addressed to Cyrnus, the young friend to whom Theognis imparts instruction in the ways of life, bidding him be true to the "good" cause, eschew the company of "evil" men (democrats), be loyal to his comrades, and wreak cruel vengeance on his foes. Theognis lived at Megara on the Isthmus of Corinth during the democratic revolution in the 6th century B.C.; some critics hold that he witnessed the "Persian terror" of 590 and 580; others, including the present writer, place his *floruit* in 545 B.C. We know little about his life; few of the details usually given in text-books are capable of proof; we are not certain, for instance, that the poem (783–88) which mentions a visit to Sicily, Sparta and Euboea comes from the hand of Theognis himself; but that is of little concern, for we know the man. Whether, with Harrison, we hold that Theognis wrote "all or nearly all the poems which are extant under his name" or follow the most ruthless of the higher critics (Sitzler) in rejecting all but 330 lines, there is abundant and unmistakable evidence to show what Theognis himself was. However much extraneous matter may have wormed its way into the collection, he still remains the one main personality, and stands clearly before us, a living soul, quivering with passion and burning with political hate, the very embodiment of the faction-spirit (*stasis*) and all it implied in the tense city-state life of the ancient Greek.

There is neither profound thought nor sublime poetry in the work of Theognis; but it is full of sound common-sense embodied in exquisitely simple, concise and well-balanced verse. As York Powell said, "Theognis was a great and wise man"; he was an able exponent of that intensely practical wisdom which we associate with the "seven sages of Greece." Had he lived a century later, he would probably have published his thoughts in prose; in his day verse was the recognized vehicle for political and ethical discussion, and the gnomic poets were in many ways the precursors of the philosophers and the sophists, who indeed often made their discourse turn on points raised by Theognis and his fellow-moralists. No treatment of the much-debated question "Can virtue be taught?" was regarded as complete without a reference to Theognis 35–36, which appears in Plato, Xenophon, Aristotle, Musonius and Clement of Alexandria, who aptly compares it with Psalm xviii. 26. Another famous couplet is 177–78: "In poverty, dear Cyrnus! we forego | Freedom in word and deed—body and mind, | Action and thought, are fetter'd and confin'd" (trans. Frere), discussed by Aristotle, mercilessly criticized by Lucian and the Stoics, and warmly commended by Ammianus Marcellinus, who introduces the author as "Theognis poeta vetus et prudens." For many generations Theognis was to the Greeks the moralist *par excellence*; Isocrates says that Hesiod, Theognis and Phocylides were admitted to be the best teachers of practical morality; and the Emperor Julian in his defence of paganism asks whether "the most wise Solomon is equal to Phocylides or Theognis or Isocrates."

Besides the elegies to Cyrnus the Theognidea comprise many maxims, laments on the degeneracy of the age and the woes of poverty, personal admonitions and challenges, invocations of the gods, songs for convivial gatherings and much else that may well have come from Theognis himself. The second section ("Musa Paedica") deals with the love of boys, and, with the exceptions already noted, scholars are at one in rejecting its claim to authenticity. Although some critics assign many elegies to a very late date, a careful examination of the language, vocabulary, versification and general trend of thought has convinced the present writer that practically the whole collection was composed before the Alexandrian age.

Editions.—Imm. Bekker (1815, 2nd ed. 1827); F. G. Welcker (1826); both these are epoch-making books which no serious student can ignore; Th. Bergk (1843, 4th ed. 1882; re-edited by E. Hiller, 1890, and O. Crusius, 1897); J. Sitzler (1880); E. Harrison (1902); T. Hudson-Williams (1910). For further bibliographical references see the two last-mentioned books. There is a prose translation by J. Banks in Bohn's Classical Library (1856), which also includes verse translations by J. Hookham Frere.

(T. H. W.)

THEOLOGY, literally the science which deals with God or the gods. The word is Greek (Θεός, God; λόγος, theory). But doctrine counted for less in Greek or Roman religion than in Christianity, and forms of worship for more. In the oldest usage θεολόγοι were those who dealt in myths, like Hesiod and like the supposed Orpheus, the θεολόγος *par excellence*. Paul Natorp[1] contends that θεολογία in Plato's *Republic* refers wholly to the control of myths. He further denies that Aristotle identified his First Philosophy with a "theology," holding the text of the *Metaphysics* to be out of order and

[1] *Philosophische Monatshefte* (1888), Heft 1 and 2. See also Theism.

corrupted, though from a very early period. He regards the Stoics as having initiated a philosophical theology, and gives numerous references for the "three theologies" which they distinguished. Philo the Jew is also quoted as using θεολόγος of poets, of Moses *par excellence*, and of Greek philosophers. It is possible that the epithet θεολόγος for St John may go back as far as Papias. This is the first appearance of the term upon Christian ground. The primitive application of θεολόγοι to the poets and myth-fanciers meets us again in Church writers; but there is also a tendency to use the name for a philosophical theology based on the doctrine of the Logos. In this sense Gregory Nazianzen also receives the title θεολόγος. His περὶ θεολογίας is a dissertation on the knowledge of God.[1] Many centuries later Abelard generalized the expression in books which came to bear the titles *Theologia Christiana* and *Introductio ad Theologiam*. (Abelard speaks himself of "theologia nostra.")[2] It is of interest to note that even in these books the Trinity and Christology are the topics of outstanding importance. In the *Summa Theologiae* of Thomas Aquinas the technical sense is fully established. Except in special circumstances which generally explain themselves, *e.g.* "Homeric Theology" (a book by Nägelsbach), Old Testament Theology, Comparative Theology, Natural Theology, the word in modern languages means the theology of the Christian Church. What follows here will be confined to that subject.

Contents of theology.

While the word points to God as the special theme of the theologian, other topics inevitably find entrance. Theistic philosophy thinks of God as the absolute being; and every monotheistic religion insists, not indeed that the knowledge of God includes all knowledge, but that this supremely important knowledge throws fresh light upon everything. So, with an added Christian intensity, St Paul declares: "If any man is in Christ, he is a new creature; the old things are passed away; behold, they are become new. But all things are of God, who reconciled us to himself through Christ" (2 Cor. v. 17, 18). A minimum division might be threefold—*Gottesbegriff*, *Selbstbeurteilung*, *Weltanschauung*.[3] But historically it is more important to note that Christian theology has developed as a doctrine concerning Christ: his relation to God, our relation to God in or through him. For Christ is viewed as bringing redemption—a conception of importance in many religions, but in none so important as in Christianity. Indeed, another possibility opens up here. Instead of being mainly a doctrine concerning God, or one concerning Christ, theology may be construed as being mainly the theory of Christian experience. Most schools of theology will concur, however, in giving prominence to a complementary point of view and making their systems a study of Divine *revelation*. Even if they accept Natural Theology, they generally hold that Christian theology, properly so called, begins at a further point. Those who deny this were formerly called Naturalists, *i.e.* deniers of *supernatural* revelation; those who extend the province of reason in theology, and push back the frontier of revelation, are often called Rationalists.[4] Such being the usual point of view, it is plain that the claim of theology to be a science, or a group of sciences, is made in a sense of its own. In so far as theology is orderly, coherent, systematic, and seeks to rest upon good grounds of some sort, it may be called a science. But, in so far as it claims to deal with special revelation, it lifts itself out of the circle of the sciences, and turns away from natural knowledge towards what it regards as more intimate messages from God.

Theology as a science.

Two special usages should be noted: (1) a medieval use of "theology" for mystical or intuitive knowledge of God, as in the well-known book called *Theologia Germanica;* (2) "theology proper," in Protestant systems, is the portion of theology which deals directly with the doctrine of God.

Theology and Religion.

Another characteristic of theology is its secondary and reflective character. Religion, therefore, is earlier than theology. Or the theology which religion contains is in a state of solution—vaguely defined and suffused with emotion; important practically, but intellectually unsatisfying. "Scientific" theology contrasts with this as a laboratory extract. History may soften the contrast by discovering transitional forms, and by showing the religious interest at work in theology as well as the scientific interest affecting early utterances of religion. Still, this contrast enters into the meaning of divines when they say that they are at work upon a science. A religious man need no more be a theologian than a poet need have a theory of aesthetics.

Sources.

Where, then, are we to look for Christian theology? It is not the truism it may seem if we reply that we are to find it in the writings of theologians. As authorities controlling their work, theologians may name the Bible, or tradition, or the religious consciousness, or the Church, or some combination of these. But the teaching of the Bible is not systematic, and the authority of consciousness is vague; while the creeds into which Church tradition crystallizes emerge out of long theological discussions. Ordinarily, doctrine has been in close connexion not only with edification but with controversy. Anselm of Canterbury stands almost alone among the great theological masters in working purely from a scientific interest; this holds alike of his contribution to theism and of his doctrine of Atonement. Among the earlier theological statements are catechetical books, *e.g.* Cyril of Jerusalem. These books record doctrinal instruction given, for practical ends, to laymen of adult years who were candidates for baptism. Disinterested discussions by experts for experts is medieval rather than primitive. Modern catechisms in the form of question and answer for the instruction of baptized children are sometimes convenient if dry summaries of doctrine (*e.g.* the Westminster Assembly's *Shorter Catechism*); but sometimes they have the glow of religious tenderness, like Luther's *Lesser Catechism*, or the *Heidelberg Catechism*. They generally expound (1) The Apostles' Creed, (2) the Ten Commandments, (3) the Lord's Prayer. Medieval theology has an appearance of keeping in touch with the Apostles' Creed when it divides the substance of doctrine into (usually) twelve "articles"—not always the same twelve—a reminiscence of the legendary composition of the Creed in twelve sections by the twelve apostles. This treatment, however, has little real influence upon the structure of medieval theology. German Protestant writers, again, following their catechisms, often distinguish three articles—of the Father, of the Son, and of the Holy Spirit. This, too, is no more than convenient phraseology.

Jewish theology.

Before the Christian age, there had been a good deal of reflective thinking in the Jewish schools, though the interest there was legal rather than speculative. To some extent Christianity inherited this Jewish theology. True, Jesus Christ sprang from the people. He was a "layman" (Paul Wernle), without technical Jewish lore. The great attainment of the Old Testament, ethical monotheism, had become the common property of the nation; it occurs in Christianity as a simple presupposition. Early Christian writers find it unnecessary to prove what no one dreams of questioning. Along with this great doctrine there pass on into Christianity the slowly attained hope of resurrection and the dreadful doctrine of future punishment for the wicked. Leading thoughts in the teaching of Jesus, so far as they are new, are the Fatherhood of God—new at least in the central place given it—the imminence of the "kingdom" or judgment of God, and Jesus' own place as "Messiah," *i.e.* as king (and as judge). The "second founder" of Christianity, Paul of Tarsus, was indeed rabbinically trained. His recoil from Judaism is all the more intense because of the special intellectual presuppositions which he continues to share with Judaism. In many respects, Pauline Christianity is the obverse of the Pharisaic creed. Modern Christians are

St Paul.

[1] Other usages of θεολογία are the Divine nature of Christ (St John Chrysostom, quoted in Konstantinides' Greek Lexicon), Old and New Testaments (Theodoret, *ib.*); Greek theology and Mosaic or revealed theology (Theodoret).

[4] A. W. Benn (*History of English Rationalism in the 19th Cent.*) goes beyond ordinary usage in defining rationalism as a militant theory opposed to all belief in God.

tempted to charge the seeming extravagance of St Paul's thought upon his Jewish inheritance, while modern Jews are tempted to stigmatize them as grotesque exaggerations of reasonable rabbinical doctrines. Probably both are right, and both wrong. The germs were Jewish; but, transported to a new soil, and watered with a new enthusiasm, they assumed new forms. These cannot claim the merit of correctness, but they are works of religious genius. At the same time, they employ all the resources of dialectic, and have, therefore, taken quite half the journey from primary religion to theology. But the dislocation of religious thinking, when Christianity ceased to be a Jewish faith and found a home with Gentiles, destroyed the continuity of Paulinism and of Jewish thought working through St Paul. In later times, when Paulinism revived, the epistles spoke for themselves, though they were not always correctly understood. It should be added that, according to A. Harnack, Hellenistic Judaism had worked out the principles of a theology which simply passed on into the Greek-speaking Christian Church.

Contents of New Testament.

Besides the teaching of Jesus (best preserved in the first three gospels) and the teaching of Paul (in six, ten, or thirteen epistles), the recent "science" of New Testament theology finds other types of doctrine. The Epistle to the Hebrews is a parallel to Paulinism, working out upon independent lines the finality of Christianity and its superiority to the Old Testament. The Johannine Gospel and Epistles are later than Paulinism, and presuppose its leading or less startling positions. Whatever historical elements may be preserved in Christ's discourses as given in the Fourth Gospel, these discourses fit into the author's type of thought better than into the synoptical framework. They have been transformed. 1 Peter is good independent Paulinism. The Epistle of James may breathe a Christianized Jewish legalism, or, as others hold, it may breathe the legalism (not untouched by Jewish influences) of popular Gentile-Christian thought. The Johannine Apocalypse is chiefly interesting as an apocalypse. F. C. Baur and his school interpreted it as a manifesto of anti-Pauline Jewish Christianity; on the contrary, it closely approaches Paul's doctrine of the Atonement and his Christology. Other writings are of less importance. Acts is indeed of interest in showing us Paulinism in a later stage; the writer wishes to reproduce his great master's thought, but his Paulinism is simplified and cut down. Possibly the Pastoral Epistles show the same process. When we go outside the New Testament, this involuntary lack of grasp becomes even more marked.

Neither the theory of infallible inspiration, with its assertion of absolute uniformity in the New Testament, nor Baur's criticism, with its assertion of irreconcilable antagonisms, is borne out by facts. The New Testament is many-sided, but it has a predominant spiritual unity. Only in minor details do contradictions emerge. It is to be remembered that criticism has broken up the historical unity of the New Testament collection and placed many of its components side by side with writings which have never been canonized, and which conservative writers had supposed to be distinctly later. But in regard to date there has been a remarkable retreat from the earlier critical assertions. And at any rate, since the New Testament canon was set up, New Testament writings have had a theological influence which no others can claim.

"Enthusiasm."

On both sides of the great transition from being a Jewish to being a Gentile faith, Christianity, according to recent study, manifested itself as "enthusiastic." We may distinguish several points in this conception. (1) Most important, perhaps—the end of the world was held to be close at hand. "Kingdom of God" as generally used was an eschatological concept; and, whatever difficulties there may be as to certain gospel passages, Christ, to say the least, cannot have disclaimed this view. The watchword rings through all the New Testament—"the Lord is at hand." A broader popular form was given to this expectation in "Chiliasm"—the doctrine of the "Thousand" years' reign[1] of Christ on earth (Rev. xx. 1-7). But even Chiliasm—which itself has its subtler and its grosser modifications—is found in early Gentile as well as in early Jewish Christianity. (2) 1 Corinthians shows us a Christian community filled with disturbances, and apparently without recognized officials. The democratic, or rather theocratic, rights of the spiritual man were for a time relied on to extemporize so much Church government as might be needed till the Master returned. Yet the beginnings of Church order come earlier than those of doctrine proper, and much earlier than the cooling of eschatological hopes. (3) There are traces inside and outside the New Testament of aversion to receiving back into Church fellowship those who, after confessing Christ, had been guilty of grave sins. The New Testament evidence is by no means uniform (contrast Heb. vi. 4-6, x. 26-31; 1 John v. 16; with 2 Cor. ii. 7); but this high conception of Church *holiness* is attested by a series of rigorist "heresies" during the early centuries; and nothing could be more characteristic of eschatological enthusiasm. Those who had fallen were not banished from hope, even by the rigorists. Still, their case was held over for a higher Judge; while the Church, especially in these more Puritan and separatist groups, kept her garments white. (4) The enthusiastic view of the possibilities of the Christian life—associated, as modern and especially Western Christians must suspect, with shallow external views of sin—lent itself to belief in sinless perfection. Even St Paul has been supposed, not without a certain plausibility, to teach the sinless perfection of real Christians. The West, with its theology protesting in the background, but in vain, still sings the prayer of the *Te Deum:* "Vouchsafe, O Lord, to keep us this day without sin."

Material for theology.

Such an enthusiastic temper does not lend itself to cool theory. Why should theology labour at definitions? "The Lord is at hand;" a Christian's one wisdom is to be ready to meet him. And yet materials for theology were richly provided even during this period. That is true above all of the man whom we know best in New Testament days—St Paul. Himself through and through animated with the joyful hope, even when prepared to surrender (2 Cor. v. 8; Phil. i. 23, ii. 17) the prospect of personal survival (1 Thess. iv. 17; 1 Cor. xv. 51, 52) until that bright day, yet as a teacher he lays such stress upon Christ's first coming that the emphasis on the second Advent may be struck out—leaving still, we might almost claim, a complete Paulinism. He who planned his campaigns to the great civilized centres of Corinth, Ephesus and Rome, and thus prepared for a historic future of which he did not dream, drew his parallels of thought with no less firm hand, and showed himself indeed "a wise master-builder."

In one aspect Montanism is the central reaction of the primitive Christian enthusiasm against the forces which were transforming its character. Of course it had other aspects and elements as well. Hippolytus and Novatian repeat the protest less vehemently; Donatism shows it blended with later hierarchical ideas.

Greek influence.

But, when the enthusiasm cooled, it was Greek thought which interpreted the contents of Christianity. The process of change is called by Harnack sometimes "secularization" and sometimes "Hellenization." "Acute Hellenizing," we are told, took the form of Gnosticism. The Gnostics were the "first theologians." When the Church in turn began to produce a theology of her own she was imitating as well as guarding against those wayward spirits. What was to be the central topic? The Church's first creed had been "the Fatherhood of God and the Messiahship of Jesus" (A. Ritschl); but the "Rule of Faith" (Irenaeus; Tertullian, who uses the exact expression; Origen)—that summary of religiously important facts which was meant to ward off error without reliance on speculations such as the Logos doctrine—built itself up along the lines of the baptismal formula of Matt. xxviii. 19.[2] There are traces in the New Testament of a baptismal confession simply of the name of Christ (1 Cor. i. 13, 15; Rom. vi. 2; cf. even the late verse Acts viii. 37), not of the threefold name. Moreover, textual criticism points to an early type of reading in Matt. xxviii. 19 without the threefold formula. Still, it is strange how completely this seemingly isolated passage takes command of the development of early theology.

Doctrine of Trinity and of Person of Christ.

Out of the Rule of Faith there came in time what tradition miscalls the Apostles' Creed—the Roman baptismal creed, a formulary of great importance in all the West; then other creeds, which also are in a sense expansions of the Rule of Faith. The Greek mind threw itself upon the problem—who precisely is Jesus Christ the Lord? His Messiahship is asserted; who then is the Messiah? and this second figure in the baptismal confession? A provisional answer, linking Christian theology with the philosophical theology of antiquity, asserted Jesus Christ to be the divine Logos. But this assertion was expanded and refined upon till two great doctrines had been built up—that of the Trinity of divine Persons in the unity of the Godhead, and that of the union of two distinct natures, divine and human, in the person of Jesus Christ. It is curious that the Syrian church of the 4th century (*e.g.* Aphraates) was almost unaffected by the great dogmatic debates. But there is no hint of a reasoned rejection of Greek developments in favour of primitive simplicity, still less of any independent theological development. Aphraates accepts the Logos Christology, and, soon after his time, his church is found on the beaten track of orthodoxy.

[1] *Four hundred* years is another significant figure in the Jewish book, 4 Ezra.

[2] If Harnack is right in regarding a New Testament canon as one of the "Apostolical authorities" which the Church brought into the field against Gnosticism, we see the truth on historical grounds of the position taught on dogmatic grounds by R. Rainy (*Delivery and Development of Christian Doctrine*)—scriptural faith not the starting-point but the goal of theological development. The starting-point is rather the "Rule of Faith."

Modern Christians generally trust this development; and all of them must admit that it seeks to answer a question arising out of the elements of New Testament belief. There is one God; but also there is one Lord; how are the two related? The strongest claim that can be put forward for the doctrine of the Trinity is that it is loyal to Christ without being disloyal to the Divine unity. Concurrently, there was a speculative or philosophical interest; and some prefer to defend Trinitarianism as a reconciliation of the personality with the infinity of God. But the biblical materials worked up in the doctrine betray little sign of any except a religious interest. We may take it as well established that St Paul (2 Cor. viii. 9: Phil. ii. 5–11) taught the personal pre-existence of Christ. A. M. Fairbairn (*Phil. of Christian Religion*, p. 476) has argued that Paul could not have given this teaching unless he had known of Christ's advancing the claim. Fairbairn barely refers to the Fourth Gospel in this connexion, and it is doubtful whether Matt. xi. 27 will bear such weight as he puts upon it. Of course, we might seek to infer an unwritten tradition of Christ's words; but without pedantic ultra-Protestant devotion to written scripture, one may distrust on scientific grounds the attempt to reconstruct tradition by a process of inference. If such records as John vi. 36, viii. 58, xvii. 3, 4 can be taken as historical, we may feel certain that Jesus taught his pre-existence. If not, modern Christian minds will hardly regard the doctrine as more than a speculation. Yet we should mention another argument of some weight. There is no trace that any Jewish Christian critics challenged St Paul's Christology. This may point to its being the Christology of the whole Church. If so, who could first teach it except the one Master?

W Bousset has suggested that the title "Son of Man" (Dan. vii. 13), used by Jesus, may have come to imply for all early Christians personal pre-existence. W. Wrede and others have more boldly conjectured that the Christ's pre-existence had become an accepted element in Jewish Messianic—it certainly occurs in one portion of the Book of Enoch and in 4 Ezra[1]—and that Paul merely transferred to Jesus a doctrine which he had held while still in the Jews' religion. "Son of God" might seem to carry us further still; but the Old Testament makes free use of the title as a metaphorical honour, and we have no proof that any Jewish school interpreted the phrase differently.

Adoptionism. The rival type of early theology is known as Adoptionism or Adoptianism (*q.v.*). According to it, the man Jesus was exalted to Messianic or divine rank. It has been argued that the narrative of Christ's baptism points to an Adoptionist Christology, and that the genealogies of Jesus (through Joseph) presuppose this type of belief, if not a still lower view of Christ's person. It has further been argued that the narratives of the Virgin birth (Matthew, Luke) are an intermediate stage in Christology. When pre-existence is clearly taught (Paul, John), virgin birth, it is suggested, loses its importance; another theory of Divine Sonship has established itself. This trenchant analysis is, however, not universally admitted. Further development of doctrine weeded out the last traces of Adoptionist belief,[2] though Christ's exaltation continued to be taught in correlation to His humiliation (Phil. ii. 8), and became in due time a dogmatic locus in Protestantism.

Justin, Irenaeus, Tertullian. The lineaments of Greek Christian theology show themselves more clearly in Justin Martyr than in the other Apologists, but still more plainly in Irenaeus, who, with little speculative power, keeps the safe middle path. Tertullian's legal training as a lawyer was a curious coincidence, if nothing more, and those legal concepts which show themselves strongly in him have done much to mould the Western type of Christian theology. He had great influence on the course of Latin theology, partly through his own writings, but still more through the spell he cast upon Cyprian. At Alexandria, Clement and his great pupil Origen state Christianity in terms of philosophy. Origen's treatise, *De Principiis*, is the first and in some respects the greatest theological system in the whole of Church history. The Catechetical school was primarily meant for instructing adult inquirers into Christianity. But it had attained the rank of a Christian university; and in this treatise Origen does not furnish milk for babes; he writes for himself and for like-minded friends. Wildly conjectural as it may seem, his thinking—though partly Greek and only in part biblical—is completely fused together in his own mind. Nor does it ever suffer from lack of thoroughness. It may be summed up in one word as the theology of free will.

Origen. Unfaltering use is made of that conception as a key to all religious and moral problems. Usually, apologists and divines are hampered by the fact that, beyond a certain limited range, men cannot be regarded as separable moral units. A new world, after death, may be called in to redress the balance of the old; but anomalies remain which faith in a future immortality does not touch. Origen called in a second new world—that of pre-existence. All souls were tried once, with equal privilege; all fell, save one, who steadily clave to the Logos, and thus merited to become in due time the human soul of Jesus Christ. No higher function could be given to free will; unless, by an extravagance, some theologian should teach that the Almighty Himself had merited His sovereignty by the virtuous use of freedom. On the other hand, a shadow is cast upon the future by Origen's fear that incalculable free will may again depart from God. Human birth in a grossly material body is partly due to the pre-temporal fall of souls; here we see in Origen the Greek, the dualist (mind and matter), the ascetic, and to some extent the kinsman of the Gnostics. But he breaks away again when he asserts that God ever wills to do good, and is seeking each lost soul until He find it. Even Satan must repent and live.[3]

It was not possible that this brilliant *tour de force* should become the theology of Christendom. Origen contributed one or two points to the central development of thought; *e.g.* the Son of God is "eternally" begotten in a continuous process. But while to Origen creation also was a continuous process, an unspeculative orthodoxy struck out the latter point as inconsistent with biblical teaching; and we must grant that the eternal generation of the Divine Son adds a more distinctive glory to the Logos when it is no longer balanced by an eternal creation. While the Church thus lived upon fragments of Origen's wisdom, lovers of the great scholar and thinker, who had dominated his age, and reconciled many a heretic to his own version of orthodoxy, must submit to have him branded as a heretic in later days, when all freedom of thought was falling under suspicion.

For a time, freedom in scholarship lingered in the younger rival of Alexandria, the school of Antioch; though speculation was never so strong there. Alexandria, on the other hand, tended to be unduly speculative and allegorizing even in its scholarship. The antagonism of the two schools governs much of the history of doctrine; and behind it we can trace in part the contrast between Church Platonism and what churchmen called Aristotelianism.

Arianism. Arius, a Libyan by birth, of Antioch by training (though earlier than the greatest days of that theological school), and a presbyter of Alexandria, represents the working of Aristotelianism. His chief opponent, Athanasius, is probably the greatest Christian, if Origen is the greatest thinker, among all the Greek fathers. Few will deny that Athanasius stood for the Christian view of the questions at issue, upon the principles held in common by all disputants. Arius represented a shallow if honest intellectualism. He found it necessary to think clearly and define sharply; but Athanasius found it necessary to believe in a divine redemption. According to Harnack, Athanasius simplified the faith of his time by fastening on the essential point—human immortality or "deification" through the Incarnation of true God. Cosmic theories of the work of a Logos subordinate to the Father fell into the background.

Athanasius. Ὁμοούσιος, successfully discredited earlier as a Sabellian formula by Paul of Samosata, was now found to be the one unambiguous term which asserted that Christ was truly God (Council of Nicaea, A.D. 325) and ὑπόστασις (Lat. *persona*) became the technical name for each of the Divine Three. Athanasius himself tried to draw a distinction between affirming the Son ὁμοούσιος, and calling Him μονοούσιος. Yet it seems plain that he considered Sabellianizing reduction of the Divine Persons to phases or modes in the unity a lesser evil than regarding the Logos (with Arius) as a creature, however dignified. This was made plain by the leniency of Athanasius towards Marcellus of Ancyra.

Marcellus. In those days there was no word for "Person" as modern philosophy defines it; perhaps no word would have served the purpose of the Church if precisely so defined. The result is, however, that a critic of doctrine sometimes questions whether Athanasianism offers a definition of the mystery at all, or only

[1] The passages referred to have sometimes, but with no great probability, been regarded as Christian infiltrations.

[2] Adoptionism is one species of Monarchianism. The other species, Modalism, has its most important type historically in Sabellianism. And the name Sabellianism is often loosely applied (*e.g.* to Swedenborgianism) to any modalistic Monarchianism (Christ one phase of God. Not three persons in the Godhead, but a threefold revelation of a God strictly one in person).

[3] Harnack takes a different view of Origen; the certainty of ultimate salvation overbears free will with a sort of physical necessity. He also thinks that in Origen's esoteric doctrine the historical Christ becomes unimportant. That is a severe judgment.

a set of sanctioned phrases, and a longer list of phrases which are proscribed as heretical. The long and dubious conflicts of opinion concern Church history but left few traces on doctrine; Athanasius never flinched through all the reaction against Nicaea, and his faith ultimately conquered the Catholic Church. There is only this to notice, that it conquered under the great Cappadocians (Basil, Gregory Nazianzen, Gregory of Nyssa), who represented a somewhat different type of teaching.[1] The Trinity in Unity stood firm; but, instead of recognizing God as one yet in some sense three, men now began to recognize three Divine beings, somewhat definitely distinguished in rank each from each and yet in some sense one. Athanasius's piety is thus brought into association with the details of Logos speculation. The new type passed on into the West through Augustine, and the so-called Athanasian creed, which states an Augustinian version of Greek dogma. There is indeed one immense change. Subordinationism is blotted out, more even than by Athanasius. On these lines modern popular orthodoxy maintains the doctrine of the Trinity. It seeks to prove its case by asserting first the divinity of Christ, and secondly the personality of the Holy Spirit. The modern idea of personality, though with doubtful fairness, helps the change.

The Cappadocians.

Augustine's Trinitarianism.

The first great supplement of the doctrine of the Logos or Son was the more explicit doctrine of the Holy Spirit. Macedonius, who defended the semi-Arian or Homoiousian position that the Spirit was merely a Divine influence—Origen had held the Spirit to be a creature—was branded as a heretic (Synod of Alexandria, 362; Council of Constantinople, 381); a strong support to Cappadocian or modern Trinitarianism. Then, in the light of the affirmation of Christ's full divinity, the problems of His person necessarily received further attention. Did the Divine Logos take the place of the higher rational soul in the humanity of Jesus? So Apollinaris or Apollinarius of Laodicea taught, but the Council of Constantinople (381) marked the position as heretical. Did the two natures, human and divine, remain so separated in Jesus as to jeopardize the unity of His person? This was the view which Cyril of Alexandria ascribed to Nestorius, who hesitated to call Mary θεοτόκος, and represented the tradition of the Antiochene school. Such views were marked as heretical by the Council of Ephesus (431), the decision resulting in a profound and lasting schism. Did the two natures coalesce in Jesus so as to constitute a single nature? This is the Monophysite or Eutychian view, developed out of the Alexandrian tradition ("Eutychianism is simply Cyrillianism run mad," A. B. Bruce). The Council of Chalcedon (451) rejected the Alexandrian extreme in its turn, guided by Leo of Rome's celebrated letter, and thus put the emphasis on the duality rather than the unity in Christ's person. Another grave and lasting schism was the result. Two great doctrinal traditions had thus been anathematized; the narrow line of orthodoxy sought still to keep the middle track. Was there at least unity of will in Jesus? No, said orthodoxy; He had two independent faculties of will, divine and human. The Maronites of Syria, reconciled to the see of Rome in 1182, probably represent the Monothelete schism. John of Damascus's theory of Enhypostasy (Christ's manhood not impersonal, but made personal only through union with His Godhead) is held by some to be the copingstone of this great dogmatic development.

Doctrine of the Spirit.

Monophysites.

Monotheletes.

Enhypostasy.

In the Trinity the problem is to combine independence and unity; in Christology, to combine duality of nature[2] with the unity of the person. Verbally this is done; is it done substantially? The question, Who is Jesus Christ? has been pushed to the very end, and authoritatively answered in the definitions of Church orthodoxy. With these the Orthodox Greek Churches—and with their divergent decisions the various non-Orthodox Eastern Churches, Coptic, Armenian, &c.—desire to rest satisfied; theology has finished its work, unless in so far as it is to be codified. It is never true while men live that thought is at a standstill; but, as nearly as it may be true, Eastern theology has made it so. In the West the decisions of the great councils have been accepted as a datum. They enter into the basis of theology; results attained by long struggles in the East are simply presuppositions to the West; but, for the most part, no independent interest attaches to them in the Western world. They are taken as involved in redemption from sin—in the Atonement, or in the sacraments. Belief in the Trinity is almost unbroken. Western Christendom wishes to call Christ God; even the Ritschlian school uses the wonted language in the light of its own definitions. For others, the Trinity is the accepted way of making that confession. It becomes of practical importance, according to S. T. Coleridge,[3] in connexion with Redemption. It passes, therefore, as a datum of revelation. In Christology the tradition has been more frequently challenged since the Reformation.

The definitions in East and West.

Harnack criticizes the doctrinal development. He considers that Christianity is best defended on the basis of the doctrine that Christ is a man chosen and equipped for His task by God. But in the Eastern Church the religious interest, as he thinks, points to Monophysitism. Dyophysite orthodoxy has sterilized Eastern Christianity, or thrown it upon inferior forms of piety. Of course this does not mean that Harnack considers monophysitism nearer the historic truth, or nearer the normal type of Christian thought. On the contrary, he would hold that the scholarly tradition of Antioch more nearly reaches the real historical manhood of Jesus. But if it be presupposed that the purpose of Christ's mission was to deify men by bestowing physical immortality, then we must assume, first, Christ's essential Godhead, and, secondly, the fusion of His divine and human natures. Whatever be the truth in the assertion that death rather than sin is the enemy dreaded by Eastern Christianity, and immortality rather than forgiveness the blessing craved, it is difficult to take the talk about deification as anything more than rhetoric. Did they not start from belief in one God? Was not polytheism still a living enemy? It is a more obvious, if perhaps a more vulgar, criticism of the great development to say that it was too simply intellectual—seeking clear-cut definitions and dogmas without measuring the resources at the command of Christians or the urgency of their need for such things. We are sometimes told that the councils simply denied error after error, affirming little or nothing. But the Trinity and the Hypostatic Union are vast speculative constructions reared upon slender biblical data. To complain of the over-subtlety of a theological adversary is a recognized move in the game; it may constantly be played in good faith; it proves little or nothing. The facts appear to be, that the Church embarked confidently on the task of blending philosophy and religion, that the Trinity satisfied most minds in that age as a rational (*i.e.* neo-platonic) construction, but that in Christology the data or the methods proved less tractable. If two natures, divine and human, are added to each other, what can the humanity be except one drop in the ocean of divine power, wisdom, goodness? The biblical authorities plainly set forth "the man Christ Jesus," but theological science failed to explain how Godhead and manhood came together in unity. Fact and theory sprang asunder; for theory had done its utmost, and was baffled. Another admission ought to be made. Western contributions to the prolonged debate constantly tended to take the form of asserting truths of faith rather than theories. Yet what was the whole process but a colossal theory?[4]

One perplexity connected with theology is the question, How far does Christianity succeed in embodying its essential interests in its doctrines? The Orthodox Eastern Church might seem to have succeeded beyond all others. Factions of lay-folk, who quarrelled furiously over shades of opinion never heard of in the West, and scarcely intelligible to Western minds even if expounded, might seem to have placed their sincerity beyond all question. And yet there were at least two other developments which were important in the East and proved still more so in the West—the legal development and the sacramental. The name "Catholic" is one which Protestant Christians may well

Further elements in Catholicism.

[1] Harnack and F. Loofs describe them as belonging to the Homoiousian party—believers in the Son's "likeness of essence" to the Father's, not "identity of essence." Bethune Baker vehemently denies that these great leaders were contented with Homoiousianism. Anyway, we must remember that radical theology had gone to much greater extremes in denial (Anomaeans—the Son unlike the Father). It was not by any means exclusively the "battle of a diphthong."

[2] Spanish Adoptianism breaks up the unity almost without disguise.

[3] Cf. *Aids to Reflection*, Aphorism 2, Comment.

[4] A. M. Fairbairn takes the rather unusual view that Greek Christian theology was the climax of the process of Greek *philosophy*, and so far alien to piety, although he is far from banishing speculation out of theology. *Christ in Modern Theol.*, pp. 81, 90, 183.

hesitate to resign to their rivals. Yet there is convenience and no small significance in connecting the term with a certain characteristic and un-Protestant type of the Christian religion. Catholicism is not dogma only, but dogma *plus* law *plus* sacrament. From very early days Christianity was hailed as the "new law"; and the suppression of the rigorist sects, by definitely giving law supremacy over enthusiasm, aggrandized it, but at the same time aggrandized the sacraments. The Western Christian must needs hold that the Eastern development was incomplete. It laid these things side by side; it did not work them into a unity. The latter task was accomplished with no little power by the Western Church in the period of its independent development.[1] The Greek and the Roman Catholic Churches stand united against Protestantism in the general theory of law and of sacraments; but a Protestant can hardly doubt that, if Catholicism is to be accepted, a Catholic organization, and doctrine are better furnished by the Western Church than by the arrested development of its rival.

Ascetic element.

The theory of asceticism had also to be more fully worked out and better harmonized with Church authority. The priesthood had successive rivals to face. First in the period of "enthusiasm," the prophets; then the martyrs and confessors; finally the ascetics. The last, in regulated forms, are a permanent feature of Catholicism; and the rivalries of these "regular" clergy with their "secular" or parochial brethren continue to make history to-day. That the ascetic life is intrinsically higher, that not every one is called to it, that the call is imperious when it comes, and that asceticism must be developed under Church control—all this may be common to East and West. But, in the utilization of the monks as the best of the Church's forces, the Western Church far surpasses the East, where meditation rather than practical activity is the monastic ideal. In the West, "enthusiasm," in the transformation under which it survives, is not merely bridled but harnessed and set to work.

Augustine's influence.

The new developments of the West could not grow directly out of Eastern or even out of early Western conditions. They grow out of the influence of Ambrose of Milan, but far more of Augustine of Hippo; and behind the latter to no small degree there is the greater influence of St Paul. Intellectual developments do not go straight onward; there are sharp and sudden reactions. Pelagianism, the rival and contradiction of Augustinianism, represents a mode of thought which appeared early in Christianity and which could count upon sympathizers both in East and in West. But, when the Christian world was faced with the clear-cut questions, Was this, then, how it conceived man's relation to God? and Did it mean this by merit? Augustine without much difficulty secured the answer "No." In the East (Council of Ephesus, 431) he was helped by the entanglement of Pelagianism with Nestorianism, just as in the West the ruin of Nestorian prospects was occasioned partly by dislike for the better known system of Pelagianism. In Augustine's own case, reaction against Pelagianism was not needed in order to make his position clear. He may have left a vulnerable frontier in his earlier dealings with the same thorny problem of free will. Certainly his polemic as a Christian against the Manichaeism of his youth constitutes a curious preface to his vehement rejection of Pelagian libertarianism. Once again, a narrow track of orthodoxy midway between the obvious landmarks! But Augustine had a deeply religious nature, and passed through deep personal experiences; these things above all gave him his power. He was also genius and scholar and churchman, transmitting uncriticized the dogmas of Athanasianism and the philosophy of ancient Greece, according to his understanding of them. Without forgetting that Augustine was partly a symptom and only in part a cause—without committing ourselves to the one-sidedness of the great-man method of construing history—we must do justice to his supreme greatness. If earlier times lived upon fragments of Origen, the generations of the West since Augustine have largely lived upon fragments of his thought and experience. On the other hand, not even the authority of Paul and of Augustine has been able to keep alive the belief in unconditional predestination. If in the West Athanasianism is a datum, but unexamined, and not valued for its own sake, Augustinianism is a bold interpretation of the essential piety of the West, but an interpretation which not even piety can long endure—morally burdensome if religiously impressive. The clock is wound up at the great crises of history, but proceeds to run down, and does so even more rapidly in Protestantism than in Catholicism. It may be held by hostile critics that the whole thing is a delusion. More sympathetic judgments will divine unquenchable vitality in a faith whose very paradoxes rise up in new power again and again. Augustine's (erroneous) interpretation of the Millennium (Rev. xx.), as a parable of the Church's historic triumph, stands for the final eradication of primitive "enthusiasm" in the great Church, though of course millenarianism has had many revivals in special circles.

[1] Loofs declares that the very conception of a means of grace is medieval.

Even if the Augustinian stream is the main current of Western piety, there are feeders and also side-currents. Ambrose, Augustine, Jerome, Gregory the Great are known as the four Latin Fathers. Jerome is very great as a scholar, and Pope Gregory as an administrator. As a writer, too, Gregory modifies Augustinian beliefs into forms which make them more available for Church teaching—a process very characteristic of Western Catholicism and carried still further in later centuries (notably by Peter Lombard). Perhaps two side-currents of piety should be named. There is an ethical rationalism which can never be wholly suppressed in the Christian Church by the Pauline or Augustinian soteriology. One thinks one sees traces of it, though held down by other influences, in the whole of medieval theology, and notably in Abelard. It disengages itself in the 17th century as Socinianism and in the 18th as Rationalism or Deism. Secondly there is a strong side-current in the mystical tradition, which we may perhaps treat as the modified form under which the philosophical theology of the Greek Church maintained its life in the medieval West. If so, Mysticism includes in itself a prophecy of modern Christian Platonism or idealism, with its cry of "Back to Alexandria."

Ethical rationalism and mysticism.

A Western echo of the Christological controversies of the East is found in the Adoptianism of Spain 785–818). These Adoptianists do not hold that Christ the person is adopted (He is God by birth), but his *human nature* may be.[2] There might be need of this, indeed, if the Adoptianists' theory of redemption were to stand, according to which Christ had taken to Himself a sinful human nature, and had washed it clean. This extreme assertion of duality as against Christological unity was naturally marked as heretical.

Sacraments.

Great advance is made in organizing Catholic theology by the fuller theory of sacraments. The East had a tentative hesitating doctrine of transubstantiation;[3] the West defines it with absolute precision (cf. Paschasius Radbertus against Ratramnus; the fourth Lateran Council, 1215). But if the medieval Church and modern Catholics regard the Eucharist as the principal sacrament, Protestants can hardly keep from assigning the supreme place, in the medieval system, to the sacrament of penance. If early "enthusiasm" conceived the Christian as almost entirely free from acts of sin, and if Protestant Paulinism conceives the child of God as justified by faith once for all, the full Catholic theory, representing one development of Augustinianism, views the Christian as an invalid, perpetually dependent on the good offices of the Church. The number of sacraments is fixed at seven,[4] first by Peter Lombard, and the essence of the three sacraments which do not allow of repetition—baptism, confirmation, orders—is defined as a "character"[5] imprinted on the soul and never capable of being lost. We must mark the advance in formal completeness. Theology is now not merely the dogma of the Divine nature or of Christ's person; it is also a dogmatic

[2] The term Adoptianism arose at this time. Modern theologians carry it back to much earlier views.

[3] Until indeed, in modern times, Greek theology accepted the Western term and definition.

[4] This, too, has been adopted in modern Greek theology.

[5] Augustine already has this conception (Loofs). A hostile critic might say that the conception affirms the absolute worth of sacraments while absolutely declining to say what they accomplish.

theory of how the Christian salvation is conveyed through sacraments to sinful men. On the other hand, a theology which is mainly sacramental is overtaken pretty soon by dumbness. It is of the essence of a sacrament to be an inscrutable process.

Theories of legal merit, amount of debt, supererogatory goodness, and ascetic claim—representing the aspect of Catholicism as law—are more and more worked out. The occasion of the formal separation of East and West—the Western doctrine of the twofold "procession" of the Holy Spirit, incorporated in the (so-called Nicene) creed itself ("filioque")—is of little or no real theological importance. The schism was due to race rivalries, and to dislike for the ever-growing claims of the see of Rome.

An important contribution to doctrine is contained in the *Cur Deus Homo* of Anselm of Canterbury. The doctrine of Atonement, destined to be the focus of Protestant evangelicalism, has remained undefined in Catholic circles,[1] an implicate or presupposition, but no part of the explicit and authorized creeds. When treated in the early centuries, it was frequently explained by saying that Christ's sufferings bought off the devil's claim to sinful man, and some of the greatest theologians (*e.g.* Gregory of Nyssa) added that the devil was finely outwitted—attracted by the bait of Christ's humanity, but caught by the hidden hook of His divinity. Anselm holds that it was best for the injured honour of God to receive from a substitute what the sinner was personally in no condition to offer. Whatever other elements and suggestions are present, the atmosphere of the medieval world, and its sense of personal claims, are unmistakable. With Anselm Ritschl takes Abelard, who explains the Atonement simply by God's love, and thus is the forerunner of "moral" or "subjective" modern theories as Anselm is of the "objective" or "forensic" theory. It must be admitted, however, that there is less definiteness of outline in Abelard than in Anselm. He does not even deal with the doctrine as a specialist, in a monograph, but only as an exegete.

Anselm on Atonement.

Contemporaneously with the new and vivid intellectual life of an Anselm or an Abelard, the "freezing up" of traditionalism is evidenced by the preparation of volumes of *Sentences* from Scripture and the Fathers. One of the earliest of such collections is that of Isidore (*q.v.*) of Seville (560–636), who, from this and other writings, ranks among the few channels which conveyed ancient learning to the middle ages. His *Sentences* are selected almost (though not quite) exclusively from Augustine and Gregory the Great. Direct influence from the Greek Fathers upon the West is vanishing as the Greek language is forgotten. The great outburst of *Sentences* at a later time has been referred to the consternation produced by Abelard's *Sic et Non.* The modern reader can hardly banish the impression that Abelard writes in a spirit of sheer mischief. Probably it would be truer to say that he riots in the pleasures of discussion, and in setting tasks to other irresponsible and ingenious spirits. He does not fear to contrast authority with authority, upon each point in succession; the harder the task, the greater the achievement when harmony is reached! In regard to Scripture alone does he maintain that seeming error or discrepancy must be due to our misinterpretation. If throughout the middle ages Scripture is treated as the ultimate authority in doctrine, yet Abelard seems to stand alone in definitely *contrasting* Scripture with later authorities. Moderns will question the possibility of asserting Bible infallibility a priori; but it is more really startling and noteworthy that Abelard should preserve a living sense of fallibility outside the Bible.

"Sentences."

There are many great collections of *Sentences*, notably by Hugh of St Victor and Peter Lombard. The last-named—though with more continuity of texture than Isidore—quotes largely from the Bible and the Latin Fathers. If Abelard stands for the intellectual daring of scholasticism, Lombard represents its other pole—interest in piety, *i.e.* in the Church. He is almost timidly cautious. He does not open up difficulties like Abelard, but smoothes them over. This suits the coming age. The great writers of the early centuries were to tell on men's minds not in the breadth of their treatment but in a theological pemmican. And the characteristic task for living theologians was to consist in writing commentaries on the Lombard's *Sentences*; for a time these *Sentences* themselves had been suspected, but they gained immense influence.

[1] Even the Council of Trent defined what Protestants had challenged—nothing else.

Had this been all, Western theology might have sunk into a purely Chinese devotion to ancient classics. But the medieval world had not one authority but two. Thin and turbid, the stream of classical tradition had flowed on through Cassiodorus or Boetius or Isidore; through these, at second-hand, it made itself known and did its work. But before the great outburst of scholasticism, ancient literature found a somewhat less inadequate channel in Arabian and partly even in Jewish scholarship. Aristotle was no longer strained through the meshes of Boetius; and the new light inspired Roscellinus with heresy. True, we must not exaggerate this influence. There was no genuine renaissance of civilization, such as marked the dawn of modern history. The medieval world did not copy the free scientific spirit of Aristotle; it made him, so far as known, a sort of philosophical Bible side by side with the theological Bible. But it was a very great matter to have two authorities rather than one. And if any man was to be put in the preposterous position of a secular Bible, no writer was fitter for it than Aristotle. The middle ages did their best in this grouping; only here and there a rare spirit like Roger Bacon did something more, something altogether superior to his age, in showing that the faculty of independent scientific inquiry was not quite extinct. It is possible to exaggerate the influence of the revived knowledge of Aristotle; but, so far as one can trace causes in the mysterious intellectual life of mankind, that influence gave scholasticism its vigour. (See Arabian Philosophy, Scholasticism.)

Guarantees of progress.

Arabian study of Aristotle.

With the new knowledge and impulse, there came a new method. Alexander of Hales is the first to adopt it, in place of the "rhetorical" method of previous theologians. Everything is now matter of debate and argument. The *Sentences* had resolved theology into a string of headings; with scholasticism each topic dissolves into a string of arguments for and against. These arguments are made up of "rationes" and "auctoritates," philosophical authorities and theological authorities. They are as litigious as a lawsuit—without any summing up; the end comes in a moment with a text of Scripture or an utterance by one of the great Fathers. Once such a dictum has been cited, the rest of the discussion is treated as by-play and goes for nothing. "I am a transmitter," Confucius is reported to have said. The great schoolmen were transmitters—putting in order, stating clearly and consecutively, conclusions reached by wiser and holier men in earlier times. Are the systems self-consistent? Their guarantee is the tireless criticism carried on by rival systems. No parallel display of debating acuteness has ever been seen in the world's history. It is easy to underrate the schoolmen. Indolence in every age escapes difficulties by shirking them, but the schoolmen's activity raised innumerable awkward questions. On the other hand, they possessed to perfection the means of making their speech evasive. If there are hollow places in the doctrinal foundations of the Church, it will be a tacit understanding among the schoolmen that such questions are not to be pressed. Above all, one must not look to a schoolman to speak "a piercing and a reconciling word." There is no revision of the premises in debate from a higher or even from a detached and independent point of view. The premises from which he may select are fixed; many of the conclusions to be reached are also fixed. He speaks, most cleverly, to his brief, but he will not go outside it. He may argue as he likes so long as he respects the Church's decisions and reaches her conclusions.

Scholastic method.

The systems of the leading schoolmen must rank above their commentaries upon the Lombard's *Sentences*, as the greatest of all systems of theology. Especially is that honour due to St Thomas Aquinas's larger *Summa Theologiae.*[2] We may well believe that he represents scholastic divinity at its best. He is not an Augustine, still less perhaps an Aristotle, but he is the Aristotle and the Augustine of his age, the normal thinker of the present and the lawgiver of the future. He teaches the medieval Platonic realism, but he accepts the Aristotelian philosophy of his day, marking off certain truths as proved and understood by the light of nature, and stamping those which are not so proved as not understood nor understandable, *i.e.* as "mysteries,"

Aquinas.

[2] The *Summa contra Gentiles* has a more polemic or apologetic interest than the dogmatic *Summa*, but deals almost equally with the contents of Christian theology as a whole. Books i.–iii. are said to deal with what is later known as natural theology, and Book iv. with what is later known as dogmatic. But Aquinas appeals to the Bible as an authority all through. That is not the procedure of modern natural theology.

in the sense in which the term has come to be used by ages that have inherited Aquinas's thoughts. He has Augustine's Predestinarianism, stiffened (according to Loofs) by Arab philosophical determinism, and he has much of Augustine's doctrine of the grace of God, though it is flanked with doctrines of human merit which might have astonished Augustine. The seven sacraments of course have their place in the body of the system, and are exhaustively studied. When we turn to Duns Scotus, we still find realism, still predestinarianism. And yet these are rivals. An attempt has been made by R. Seeberg to interpret Duns as the forerunner of Luther in his emphasis on the practical. Expert knowledge and judicial insight must decide the point; but, so far as the present writer can judge, it is illusory to imagine that Duns points us beyond the medieval assumptions. As generally understood, Duns makes caprice supreme in God. The arbitrary divine will makes right right and wrong wrong. Here, says Ritschl, the involuntary logic of predestinarianism speaks its last word. Though he may technically be classed as an "extreme realist," Duns is the forerunner of those later Nominalists, like William of Occam, who unsettled every intellectual ground of belief in order that they might resettle belief upon Church authority, not reason but rather scepticism being for them the *ancilla domini*. Later authoritative pronouncements on the part of the Roman Catholic Church favour Thomism and disown the Occamites; though the keen hostile criticism of Harnack affirms that the Church had need of both systems—of Thomism, to champion its cause in the arena of thought, and of the Nominalist theology to aggrandize the Church as the ruling power in practice.

Duns Scotus.

When Protestantism arose, there was urgent need of reform. All sides granted that at the time, and all grant it now. Separation was not contemplated by any one at the first; this again is manifest. Yet it is also matter of plain history that Protestantism is more than a removal of abuses, or even than a removal carried out with reckless disregard of consequences. It is partly an outcome of Luther's personality—of his violence, no doubt, but also of his great qualities. It is due mainly to the dominant tradition in Church doctrine. Augustinianism reacted against attempts to tone it down in theory or neutralize it in practice, until at last it broke loose in the form of Protestantism. But Protestantism is largely due further to the Renaissance. The new knowledge enabled men to read the Bible, like all other ancient books, with a fresh mind. Finally, we have the true central cause in the Pauline doctrine of faith. Evaded by Augustinianism, it came back now, with some at least of its difficulties and paradoxes, but also with its immense attractive and dynamic power. When the Reformers went beyond Augustine to Paul, Protestantism was born.[1] Even the Counter-Reformation, so far as it was a matter of doctrine (Council of Trent, 1545–63), took the form of reaffirming a cautious version of Augustinianism.

Origins of Protestantism.

Whether Protestantism found its adequate doctrinal expression is very doubtful. Luther was no systematic thinker; Melanchthon, the theologian of the Lutheran Church, gave his system the loose form of *Loci communes*, and went back more and more in successive editions to the traditional lines of doctrinal theory—a course which could not be followed without bringing back much of the older substance along with the familiar forms of thought. To find the distinctive technicalities of Lutheranism we have to leave Melanchthon's system (and his great Reformation creed, the *Augsburg Confession*) for the *Formula of Concord* and the lesser men of that later period. In Calvin, indeed, the Reformed[2] theology possessed a master of system. We notice in him resolute Predestinarianism—as in Luther, and at first in Melanchthon too; the vehicle of revived Augustinian piety—and resolute depotentiation of sacraments, with their definite reduction to two (admittedly the two chief sacraments)—baptism and the Lord's Supper.[3] In affirming the "inamissibility" of grace in the *regenerate* (not simply in the unknowable *elect*) Calvin went beyond Augustine, perhaps beyond Paul, certainly beyond the Epistle to the Hebrews, resolutely loyal to the logic of his non-sacramental theory of grace. Yet, in contrast with the doctrine usually ascribed to Ulrich Zwingli, Calvin teaches that grace does come through sacraments; but then, nothing comes beyond the fruits of faith; from which grace all salvation springs necessarily. To use technical language, Calvinism holds that sacraments are needful *ex ratione praecepti*, (merely) "because commanded." In contrast with this, orthodox Lutheranism has to teach baptismal regeneration and consubstantiation, as well as justification by faith. It is hard to see how the positions harmonize. Zwingli and Calvin, developing a hint of Hus, introduce a distinction between the visible and the invisible Church which Melanchthon repudiates but later Lutheranism adopts. The Articles of the Church of England (19, 26) speak of the visible Church, but unless by inference do not assert a Church invisible. Upon most points Anglicanism seeks for a *via media* of its own. Resolutely Protestant in early days and even Calvinistic, it yielded to the suggestions of its episcopal constitution[4] and sacramental liturgies; and now its theologies range from Calvinism at one extreme to outspoken hatred of Protestantism at the other. Historically, great issues have hung upon the dislike by which High Lutheranism and High Anglicanism, those two midway fortresses between Rome and Geneva, have been estranged from each other.

Melanchthon.

Calvin.

[1] Roman Catholic scholars naturally hold that Paul was misconstrued, but they cannot deny that Protestant theology was directly a version and interpretation of Paulinism.

[2] The more radical Protestantism of the non-Lutheran orthodox churches is called in a technical sense "Reformed." German scholarship generally ranks the Church of England with the "Reformed" churches because of its Articles.

[3] Lutheranism seeks to add, in a sense, a third sacrament, Penance (so even Melanchthon).

It is thus plain that the stream of Protestantism was very early split up into separate channels. Did any of these theologies do justice to the great master thought of grace given to faith? Antecedently to their separation from each other the Reformers took over the theology of Greek orthodoxy as a whole. Complaints against that theology may be quoted from early writings of every Reformer, even Calvin. They knew well that the centre of gravity in their own belief lay elsewhere than in the elaborately detailed scheme of relations within the Godhead or in the Theanthropic person. But ultimately they persuaded themselves to accept these definitions as normal and biblical, and as presuppositions of Christ's saving work. The decision had immense results, both for religion and for theology. Nor did the unity of Protestant theology—Lutheran and Calvinist—confine itself to the period before the great divergence. Men of the second or third generation —often called the "Protestant Scholastics"—work together upon two characteristic doctrines which the fathers of Protestantism left vague. The Reformation doctrine of Atonement, while akin to Anselm's, differs in making God the guardian of a system of public law rather than of His private or personal honour. This conception came to be more fully defined. Christ's twofold obedience, (*a*) active and (*b*) passive, produces jointly a twofold result, (1) satisfaction to the broken moral law, (2) merit, securing eternal life to Christ's people.[5] There is no such full and careful theory of Atonement in any Catholic theology, and, according to so unbiassed a judge as A. Ritschl, it represents the last word in doctrine along the lines laid down by the Reformers. Could Catholics adopt it? Hardly; for the Protestant assertion of Christ's merit is shadowed, if any doctrine of merit in the Christian is brought in. Yet the very word reminds us of the legal piety which is characteristic of Western popular religion through all its history. We now find "merit" confined to Christ, and the usual application ruled out, somewhat as St Paul's intenser use of Pharisee conceptions destroyed instead of confirming the idea of righteousness by works. But it is by no means clear that this Protestant doctrine of Atonement is a unity. "Merit" is an intruder in that region of more strict and majestic law; yet Christ's "merit" is the only form under which the positive contents and promises of the Christian Gospel are there represented. Even the most resolute modern orthodoxy usually tries to modify this doctrine. There is a break with the past, which no revival or reaction can quite conceal.

Continued unity in Protestant doctrines.

Again, the Reformation had drawn a line round the canon—sharply in Calvinism, less sharply in Lutheranism (which also gave a *quasi* normative position to its Confessions of Faith). Anglicanism once more resembles Lutheranism with differences;

[4] Few Lutheran churches possess bishops. In Germany the "episcopal system" is a right claimed on behalf of the civil government.

[5] This is not fully formulated even in the Lutheran *Formula of Concord*, nor yet in the Calvinistic canons of Dort and Confession of Westminster, though these and other Protestant creeds have various instalments of the finished doctrine. One might add a still further distinction of the Protestant scholasticism. The Atonement imparts to the believer (*a*) forgiveness, (*b*) positive acceptance. Actual renewal is, of course, something beyond either of these.

it enjoins public reading of certain lessons from the Apocrypha and uses in worship even the "Athanasian" as well as the two more ancient creeds. On the basis of belief in inspiration we find, during the days of Protestant scholasticism, the most reckless and insane assertions of scriptural perfection. Even in our own time, popular Protestant evangelicalism joins with the newer emphasis upon conversion the two great early Protestant appeals—to Atonement and to infallible Scripture. But the Protestant Church is by no means alone in making such assertions. Other Churches make them too, though they overlay and disguise them with appeals to tradition and to the authority of the Church itself or the Fathers. The definite and limited burden had to be more definitely dealt with; hence these Protestant extravagances.

The first great rival to Protestant orthodoxy, apart from its old enemy of Rome, was Socinianism, guided by Laelius Socinus (*q.v.*), but still more by his nephew Faustus. Thoroughly intellectualist, and rational, and supernaturalist, it has no one to champion it to-day, yet its influence is everywhere. Jesus, a teacher who sealed His testimony with His blood, and, raised from the dead, was exalted or adopted to divine glory, thus giving to men for the first time the certainty that God's favour could be won and eternal life enjoyed—such is the scheme. There is no natural theology; the teachings so described are really part, or rather are the essence, of the revelation of Jesus. Atonement is a dream, and an immoral dream. Supernatural sacraments of course drop out. The Lord's Supper is a simple memorial. Baptism were better disused, though Faustus will leave the matter to each Christian man's discretion. There is not in all Church history any statement of doctrine better knit together. Socinus's church is a school—a school of enlightenment. He was also—like Calvin, if on more narrowly common-sense lines—an admirable exegete. Harnack ranks his system with Tridentine and post-Tridentine theology on the one hand, and with Protestantism on the other hand, as the third great outcome of the history of dogma. Nevertheless the judgment of history declares that this brilliant exploit was entirely eccentric, and could only in indirect ways subserve theological study. Those to-day who are nearest the Socini in belief are as far as any from their fashion of approaching and justifying their chosen version of Christian doctrine.

Socinianism.

Even after the loss of the Protestants and the suppression or expulsion of the Jansenists, the doctrinal history of the Church of Rome is described as governed by discussions in regard to Thomist Augustinianism. The Molinists (*i.e.* followers of Louis Molina the Jesuit, not Michael Molinos the mystic) are the leading representatives of a different theology. Harnack, a keenly hostile critic, draws attention to a change in the region of moral theology, not dogmatics. After long controversy, St Alfonso Liguori's doctrine of Probabilism (originated by Molina) definitely triumphed everywhere. Conduct is considered lawful if any good Church authority holds it to be defensible; and "probability" warrants the confessor in taking a lenient view of sins which he himself, and authorities of weight in the Church, may regard as black in the extreme. From Harnack's point of view, the theory destroys Augustinianism, whatever honour may still be paid to that name. Another important change in Roman Catholic theology has been the increasing personal power of the pope. This was significantly foreshadowed when Pius IV. put forward by his own act what is known as the creed of the Council of Trent; and, after the coldness of the 18th century and the evil days of the French Revolution, an Ultramontane revival, relying with enthusiasm on the papacy, grew more and more strong until it became all-powerful under Pius IX. It gained a notable victory when that pope, acting on his own authority, defined (1854) as of faith a doctrine which had been long and hotly discussed—the Immaculate or absolutely sinless Conception (deeper than mere sinlessness in act and life) of the Blessed Virgin. The second and decisive victory followed at the Vatican Council (1870), which, at the cost of a small secession of distinguished men, declared the pope personally infallible (see INFALLIBILITY) and irreformable as often as he rules *ex cathedra* points of faith or morals. This once again seems to be the last word in a long development. Uncertainty as to the authorities determining religious belief—Scripture, tradition, Fathers, Doctors—is now, at least potentially, at an end; the pope can rule every point definitely, if he sees good to do so.

Later history of Roman Catholic doctrine.

The theory of Development (J. A. Möhler, J. H. Newman), which throws so new a light upon the meaning of tradition, is a valuable support of the conception of a sovereign pontiff drawing out dogmas from implicit into explicit life. Still, new and obscure questionings may still arise. When is the pope ruling faith and morals from his throne? When may the Church be assured that the infallible guidance is being given? A startling fresh development is suggested by Harnack, while vehemently dismissed as impossible by another Protestant scholar, H. M. Gwatkin. May a reforming or innovating pope arise? He would find, in theory at least, that he possessed a weapon of matchless power and precision. But hitherto Roman Catholic theology has refused to conceive of any development except by enlargement of the Church's creed. Much may be added to formulated belief; it is not admitted that anything has been or can be withdrawn. Brilliant Modernist scholars like A. Loisy may have successors who will champion theories of evolutionary transformation. But at the present hour a representative writer names as a typical open question in his communion the Assumption of the Virgin. Perhaps, indeed, it is rather a dogma hastening towards definition. Is the theory or tradition correct, that, after death and burial, Mary was bodily received into heaven and her grave left empty? Such problems engage the official theologians of the Church of Rome.

Modern theory of "development."

It is natural that the "variations" with which Bossuet reproached the Protestants should demand more space. The Christological problem seems to require separate treatment. In regard to the Trinity, Protestantism has nothing very new to say, though "Sabellianism" is revived by Swedenborg and Schleiermacher. But in regard to Christology opinion takes fresh forms as early as Luther himself. While this became conspicuous in connexion with his doctrine of consubstantiation in the Eucharist, it appears[1] that he had a genuine speculative interest in the matter. *Communicatio idiomatum* was well known in the schools as an affair of terminology. You might say correctly that God has died (meaning the Godman), or that a man is to be worshipped —Christ Jesus. According to Luther, however, it is not merely in words that the attributes of the Godhead qualify Christ's human nature.[2] That takes place in fact; and so the human glorified body of Christ is, or may become under conditions which please Him, *e.g.* at the Eucharist, ubiquitous. This new quasi-monophysitism disinclined the Lutherans to make much of Christ's humanity, while the Reformed, partly from the scholarly tradition of Calvin, partly from a polemical motive, laid great emphasis on the manhood. A. Ritschl[3] even speaks of the Reformed as teaching Kenosis in the modern sense; but it is to be feared they rather taught alternately the manhood and the Godhead than made a serious effort to show the compatibility of divine and human predicates in one person. Christ as man was one of the Elect (and their head); He needed grace; He depended upon the Holy Spirit. On the other hand, as God, He was the very source of grace. The Lutherans held that the Incarnate One possessed all divine attributes, but either willed to suspend their use—this is the Kenosis doctrine of the Lutheran school of Tübingen in the 17th century—or concealed their working; the latter was the doctrine of the Giessen school.

Protestant history of doctrines.

A theory which flickers through Church history in the train of mystical influence proceeding from the pseudo-Dionysius Areopagita has become more prominent in modern times—that Christ would have become Incarnate even had man not sinned. Rejected by Thomas, it is patronized by Duns—not, one thinks, that he loved rational certainties more, but that he loved redemptive necessities

"Necessity" of Incarnation.

[1] According to I. A. Dorner.

[2] The human predicates are not held to modify the Divine nature, except by modern Kenoticists, who therefore, when they are Lutherans, claim to be completing Luther's theory.

[3] *Rechtfertigung u. Versöhnung*, i. p. 384.

less. In a sense this theory puts the coping-stone upon Christological development. If we are warranted in regarding the Second Person of the Godhead as in very deed "Himself vouchsafing to be made," that great Becoming cannot well be suspended upon a contingency which might or might not arise; and theologians in general regard the sin of man as such a contingent event. Incarnation almost demands to be speculatively interpreted as the necessary last stage in the self-manifestation and self-imparting of God. Yet interest in man's moral necessities threatens to be lost amid this cosmological wisdom. Theology pushed too far may overleap itself. Those who shrink from the old confident assertion, "Christ would not have become incarnate but for man's sin," might claim to say, from reverence and not from evasiveness, *ignoramus*. On the other hand, the type of thought which would perfect Christianity in the form of a philosophy, and subordinates Atonement to Incarnation, is pledged to this doctrine that Incarnation was a rational necessity. Such speculative views are associated with the revival of another traditional piece of mysticism—the Holy Spirit the *Copula* or bond of union in the Godhead. There is no such assertion anywhere in the New Testament.

Modern theories of Kenosis.

For modern German theories of *Kenosis* among Lutheran and Reformed, see A. B. Bruce's *Humiliation of Christ*. Basing on the language of Phil. ii. 7, they teach, in different forms, that the Son of God became a man under human limitations at conception or birth, and resumed divine predicates at His exaltation. It might be put in this way—a really Divine personality, a really human experience. Strong as are the terms of Phil. ii. 7, we can hardly suppose that St Paul had a metaphysical theory of Christ's person in view. In Great Britain and America many have adopted this theory. It is often taught, *e.g.* that Christ's statements on Old Testament literature are to be interpreted in the light of the Kenosis. The enemies of the theory insist that, while it safeguards the unity of Christ's personal experience at any one point, it breaks up by absolute gulfs the continuity of experience and destroys the identity of the person. Indeed, those forms of the theory, which give us a Logos in heaven (John iii. 13) along with the humbled or Incarnate Christ on earth, seem to fail of unifying experience even at the single point. Other suggestions in explanation of the mystery have been:

Other Christological speculations.

a gradual Incarnation, the process not being complete until Christ's exaltation (I. A. Dorner's earlier view); impersonal pre-existence of the Logos, who became personal—compare and contrast Marcellus of Ancyra—at the Incarnation (W. Beyschlag's earlier view, practically adopted by Dorner in his later days); Jesus the man who was absolutely filled with the consciousness of God (Schleiermacher); Jesus not to be defined in terms of "nature," either human or divine, but as the perfect fulfiller of God's absolute purpose (A. Ritschl's view, practically adopted in later days by Beyschlag). The orthodoxy which refuses all new theories may look for help to the pathological dissociation of personality, or at least (*e.g.* J. O. Dykes in *Expository Times*, Jan. 1906; Sanday *Christologies Ancient and Modern*) to the mystery of the subconscious.

We have now to look at Protestant theology in its dealing with questions in which it is more immediately or more fully interested. In the early period known as the Protestant scholasticism there was no desire for progress in doctrine.

Arminianism.

Challenged by Arminianism in Holland, the Calvinistic theology replied in the Confession of Dort; at which Synod English delegates were present. This creed may almost rank with the Lutheran *Formula of Concord* as summing up post-Reformation Protestant orthodoxy. But the direct fate of Arminian teachers or churches was no measure of their influence. One proof of the latter is found in Archbishop Laud and the English High Churchmen of his school, who throw off the Augustinian or Calvinistic yoke in favour of an Arminian theology. Lutheranism had set the example of this change. Later editions of Melanchthon's *Loci Communes*, generously protected by Luther, drop out or tone down Luther's favourite doctrine of predestination. The Augustinian clock was running down, as usual. In the 18th century "Illumination"—an age

The "Illumination."

which piqued itself upon its "enlightenment," and which did a good deal to drive away obscurity, though at the cost of losing depth—Deism outside the churches is matched by a spirit of cool common-sense within them, a spirit which is not confined to professed Rationalists. Civil wars and theological wranglings had wearied men. Supposed universal truths and natural certainties were in fashion. The plainest legacy of the 18th century to later times has been a humaner spirit in theology. Christian teachers during the 19th century grew more reticent in regard to future punishment. The doctrine when taught is frequently softened; sometimes universalism is taught.

Unitarianism.

A movement towards Arianism and then towards Socinianism (Joseph Priestley, Nath. Lardner, W. E. Channing) among English Presbyterians and American Congregationalists left permanent results in the shape of new non-subscribing churches and a diffusion of Unitarian theology (J. Martineau). The 18th century is very differently interpreted in different quarters. Orthodox evangelicalism is tempted to view it as an apostasy or an aberration. On the other hand, not merely agnostics like Leslie Stephen but Christian theologians of the Left like Ernst Troeltsch regard it as the time when supernaturalism began decisively to go to pieces, and the "modern" spirit to assert its authority even over religion. A. Ritschl, again, claims that neglected elements of Christianity were striving for utterance, particularly a serious belief in God as Father and in His providential care. It was not, says Ritschl, a turning away from Christian motives, but a turning towards neglected Christian motives. This view seems logically to involve Ritschl's belief, that it is not the light of reason but the revelation of Christ which warrants the assertion of God's fatherly providential goodness.

Whether temporary or permanent, a great reaction from the 18th-century spirit set in. It was partly on Augustinian lines, partly on the lines of what the Germans call Pietism.

The Evangelical revival.

Under John and Charles Wesley, a system known as Evangelical Arminianism was worked out in 18th-century England, strongly Augustinian in its doctrines of sin and atonement, modern Augustinian in its doctrine of conversion, strongly anti-Augustinian in its rejection of absolute predestination. Within the Anglican Church, however, the new revival was Augustinian and Calvinistic, till it gave place to a Church revival, the echo or the sister of the Ultramontane movement in the Church of Rome.

The Oxford Movement.

The vigorous practical life of the modern school of High Church Anglicanism, initiated by John Keble, W. Hurrell Froude, J. H. Newman, E. B. Pusey, is associated with a theological appeal to the tradition of the early centuries, and with a strongly medieval emphasis upon sacramental grace. In Germany, dislike of the Prussian policy of "Union"

Lutheran opposition to the "Union."

—the legal fusion of the Lutheran and Reformed Churches—gave life to a High Lutheran reaction which has shown some vigour in thought and some asperity in judgment (E. W. Hengstenberg; H. A. C. Haevernick; dogmatic in G. Thomasius and F. A. Philippi; more liberal type in C. F. A. Kahnis; history of doctrine in G. Thomasius). The most distinguished of the theologians classed as "mediating" are C. Ullmann, C. I. Nitzsch and Julius Müller. Later evangelicalism in the English-speaking lands gives up belief in predestination, or at least, with very few exceptions, holds it less strongly. That change is clearly a characteristic feature of 19th-century theology.

Many of the movements just mentioned are, at least in design, pure reactions involving no new thoughts. Apart from apologetics or single doctrines like that of the Atonement,

Proposals to unify theology.

the task of rethinking Christian theology upon the great scale has been left chiefly to German science, philosophical and historical. If the task is to be accomplished, then, whatever merit in detail belongs to wise and learned writers already referred to, it would seem that some one central principle must become dominant. This consideration, as far as an outsider can judge, excludes any formal Roman Catholic co-operation in the suggested task. So long as theological truth is divided into the two compartments of natural or rational theology and incomprehensible revealed mysteries, there is no possibility of carrying through a unity of principle. Again, many Protestants rule themselves out of participation in the search for unified doctrine. It is a modern commonplace—Loofs dates the formula from about 1825—that

Protestantism has two principles: a "formal principle," the authority of Scripture, and a "material principle," the doctrine of justification by faith. We have already indicated that some such pair of principles was prominent when historic Protestantism pulled itself together for defence during its scholastic age. But surely serious thought cannot acquiesce in a dual control. While the double authority continues or is believed to continue in power, there seems no hope of making theology a living unity, which will claim respect from the modern age.

Influence of Hegelianism.

One great attempt at unifying Christian theology came from the side of philosophy. Kant's scheme, which in religious theory as well as in chronology may be regarded as a link between the 18th and 19th centuries, led on to the very different scheme of Hegel; and the latter system began almost at once to influence Church doctrine. D. F. Strauss (*q.v.*) applied it with explosive effect to the study of the life of Jesus. F. C. Baur, assisted by able colleagues, if hardly less revolutionary, was much more in touch with theology than Strauss had been. The Hegelian threefold rhythm was to run through all history, especially for Baur through the history of the Christian Church and of its doctrine. Baur maintained a thorough-going evolutionary optimism. "The real was the rational" from first to last. However biassed, this a priori study had its merits. It unified history with a mighty sweep, and revealed through all the ages one evolving process. But we have still to ask whether the doctrines it made prominent are really those which are vital to the Christian Church. And we have to look into Baur's esoteric interpretation of the doctrinal development. For him, as for Strauss, the unity of God and man is the central truth, of which Christ's atoning death is a sort of pictorial symbol. This implies that the whole of Western theology has been an aberration or an exoteric veiling of the truth.[1] In Dogmatic the school is represented by A. E. Biedermann, and with variations by O. Pfleiderer. A more orthodox reading of Hegel's thought, which brings it into line with some Christological developments already described, is found in J. E. Erdmann and the theologians P. K. Marheineke and Karl Daub. Influences from Hegel are also to be traced in Richard Rothe, I. A. Dorner, A. M. Fairbairn; and through the mediation of British philosophers Hegelianism has widely affected British theology.

Influence in England.

The orthodox wing of idealists take as their watchword Incarnation; Christianity is "the religion of the Incarnation" (sub-title of *Lux Mundi;* see B. F. Westcott, *passim*). The rationalist wing resolve Incarnation and still more Atonement into symbols of philosophical truth. Of the two parties, the latter appears the more successful in accomplishing the task of unifying theology, although at the cost of subordinating both theology and religion to philosophy. The strength of all the idealists consists in their appeal to reason.

Schleiermacher.

Schleiermacher set himself to explain what is *distinctive* in religion. He distinguishes religion from philosophy as feeling in contrast with thought; but when he has done that (*Reden über die Religion*, 1799) he has little to add. Any type of highly wrought feeling may make a man religious, whether it be theistic or pantheistic; indeed, as a child of Romanticism, Schleiermacher puts a peculiarly high estimate upon the pantheistic type. What else can we expect from a thinker who is interested simply in feeling as feeling? When he wrote his *Glaubenslehre* (1821) Schleiermacher had become much more of a Christian churchman. "Christianity is one of the teleological pieties," and has as its peculiarity that "in it everything is referred to the redemption accomplished through Jesus of Nazareth." But it is doubtful whether the elements of his final synthesis really interpenetrate. He tells us (*Kurze Darstellung des theologischen Studiums*, 1811) that the theologian, while himself loyal to his Church, must expound, as a historian, the beliefs actually held in the branch of the Church which he represents. Oil and water do not mix. Do the unchecked individual enthusiasm of the *Reden*, and the loyalty to established beliefs required in the later writings, combine to form a living theology? It is little wonder if Schleiermacher attains a compromise rather than a unity. He has been one of the great ferments in modern Protestant doctrine both of the Right and of the Left. Alex. Schweizer[2] maintained his general positions more nearly than any other. But there is no Schleiermacher school. W. Herrmann, from his own point of view, has quoted J. C. K. Hofmann and F. R. Frank as making important modifications and sometimes corrections of the lines laid down by Schleiermacher, while J. S. Candlish, representing a moderate Scottish Calvinism, was half inclined to welcome the reduced form of Schleiermacher's basis found in H. L. Martensen (a Dane), J. T. Beck, and the Dutchman, J. J. van Oosterzee, *i.e.* Scripture the true source of doctrine, but the religious consciousness its ordering principle.

[1] Hence R. B. Haldane, in the Scottish Church lawsuit of 1904, is found telling the House of Lords that Justin Martyr had a grasp of speculative truth which was impossible to St Augustine.

[2] Or the Dutchman, J. H. Scholten.

Ritschl.

A bolder and more original attempt to restate Protestantism as a systematic unity is found in the work of A. Ritschl, with H. Schultz and W. Herrmann as independent allies and colleagues, and with J. Kaftan, A. Harnack and many others as younger representatives on divergent lines. Reaction against the philosophy of Hegel and the criticism of Baur is common to all the school, though Ritschl went further back than the younger men towards critical tradition and further in some points towards orthodox dogma. Positively, the school build upon foundations laid in ethics by Kant and in philosophy of religion by Schleiermacher; so also R. A. Lipsius, and yet his dogmatic results coincide more nearly with Biedermann's or Pfleiderer's than with the "intermediate though not mediating" position taken up by the Ritschlians. Not even the acceptance of forgiveness as the central religious blessing is exclusively Ritschlian, still, it is a challenge alike to the 18th century, to the Church of Rome and to the modern mind. Ritschl and his friends forfeit that unifying of life and duty which is gained by making the moral or perhaps rather legal point of view supreme. As they deny the natural religion of the 18th century—the religion which works its way into harmony with God by virtue—so, still more emphatically, they refuse to bid the sinner merit forgiveness. Thus they constitute one more revival of Paulinism or Augustinianism, though with qualifications.

Their effort is to expound Christianity, not from the point of view of philosophy like the Hegelians, nor from that of an abstract conception of religion, tempered by regard for historical precedents, like Schleiermacher, but from its own, from the Christian point of view. Ritschl has several dogmatic peculiarities, intenser in him than in his fellow-workers and followers. A notable instance is his doctrine of the Church—the community (*Gemeinde*); the sole object of God's electing love, according to Ritschl's interpretation of St Paul. Hence theology is not to be the utterance of individual Christianity merely, but of the Church's faith, embodied in its classical literature, the New Testament, and (subordinately) in the Old. The finality of the New Testament is partly due to its being the work of minds—including St Paul—who knew the Old Testament from the inside, and did not misconstrue its religious terminology as Greek converts almost inevitably did (cf. Harnack or E. Hatch). Upon the Church, Ritschl, who very much disliked and distrusted mysticism, poured out the same wealth of emotion which the Christian mystic pours out upon his dimly visualized God or Christ. Again, Ritschl divides all theology into two compartments, morality and religion; service of men in the Kingdom of God, direct relation to God in the Church by faith. Though he later declared that "Kingdom of God" was the paramount category of Christian thought, it does not appear that he substantially recast his theology. Here then his strong desire for unity is cut across by his own action. There may well be room for relative distinctions in any system of thought, however coherent; but it looks as if Ritschl's distinction hardened into absolute dualism.

Again Ritschl modifies the doctrine of sin. Like Schleiermacher he substitutes collective guilt for original sin; and he attaches great dogmatic value to the assertion that sin has two stages—ignorance, in which it is pardonable, and obduracy, when it is ripe for final sentence (probably annihilation). Here then Ritschl swerves from Paulinism; it is in other Scriptures[3] that he finds his guarantees for the position just stated. The result is to eliminate everything remedial from the Christian gospel. Yet Ritschl claims that his doctrine of Christ as Head of the Church combines the lines of thought found separately in Anselm and Abelard, while Schleiermacher is said to have been one-sidedly Abelardian. Ritschl denies natural theology[4] as well as natural religion, denies dogma outright in its Greek forms—Trinitarian and Christological; and seeks to transpose the doctrine of Atonement—Christ's Person "or" Works as he puts it—from the legal to the ethical. The Pauline touch shows itself plainly here. Justification by faith is a "synthetic" judgment—the *sinner* is righteous; it is not an "analytic" judgment—the *believer* is righteous. God "justifieth the ungodly." Sacraments are a republication of the "Word" of the Gospel; we have to content ourselves with this rather evasive formula, so often employed by the Reformers.

The highly academic Ritschlian movement has had wide practical influence in many lands. Here English and American thought strikes in sympathetically, offering moral theories of Atonement, though not looking so exclusively towards forgiveness. Horace Bushnell's last theory declared that in forgiving sin God "bore cost," as even a good man must do. John M'Leod Campbell—with a strong desire for unity in thought, "the simplicity that is in Christ"—caught most attention by the suggestion of a vicarious repentance in Jesus Christ. With R. C. Moberly this becomes an assertion that Christ has initiated a redemptive process of self-humiliation, which we can prolong in ourselves by the help of sacraments if we choose; while W. Porcher du Bose (like E. Irving early in the 19th century) holds the Adoptianist theory styled by A. B. Bruce "redemption by sample"—the divine Christ has

[3] Unless 1 Tim. i. 13; but is that epistle Paul's?

[4] The doctrine of "value judgments" which he substitutes for Schleiermacher's appeal to feeling, belongs to philosophy of religion and is thus analogous to natural theology.

assumed a tainted human nature and washed it clean, thus making it a promise and potency of the world's redemption.

Even if we accept the programme of reconstructing theology from a single point of view, we may desire to criticize not merely Ritschl's execution of the scheme, but his selection of the ruling principle. Is it enough to extricate the spirit of Protestantism from the imperfect letter of its early creeds?

Theology and Science. One set of difficulties is raised by the progress of science. No Protestant can deny that it is a duty for Christianity to come to terms with scientific discoveries, and few Catholics will care to deny it. Anxious negotiations thus arise, which colour all modern schemes of theology. But with a certain school they become central and dominant. We distinguish this position from the new emphasis on Christology, whether churchly or radical. Those who find a gospel in philosophy are ready to dictate terms to outsiders; but those who wait upon science for its verdicts supplicate terms of peace. Just as much of Christianity is to survive as science will spare. Often the theologians in question look to psychology as the permanent basis of religion; who is to deny that religion is a psychological fact, and the natural expression of something in man's constitution? This strain may be recognized, mingled with others, in Schleiermacher; it has found interesting expression in the contributions of H. J. Holtzmann and Ernst Troeltsch to the volume dealing with Christianity in *Die Kultur der Gegenwart*. Christ is confessed as the greatest figure of the past, and as one of no small importance still for the present and future. But, with entire decision, Christianity is called to the bar of modern culture. From that tribunal there is to be no appeal, whether to a higher revelation or to a deeper experience. This view stands in connexion with the study of comparative religion. Out of that very Ritschl school, which began by despising all religions except those of the Bible, has developed the *religionsgeschichtlich* movement, which dissolves Christianity in the wider stream. Such a policy is at the opposite pole to Ritschl's; he desired to interpret Christianity in the light of its own central thought. If Christians can find in their faith new resources to meet the new needs, they may hope to command the future. Theology if it is to live must be henceforth at once more Christian and more scientific than it has ever yet been.

A less threatening yet important possibility of modification arises out of the scientific study of the New Testament.

Theology and New Testament scholarship. Augustine, Luther, the evangelical revival, went back to St Paul; can Christianity not dig deeper by going back to Jesus? A Protestant has to view the past history of doctrine very much as a succession of declensions and revivals, the latter more than counteracting the former. He does not claim to have regained the inspiration of a Paul; but he holds that Augustine was more Christian than the sub-apostolic age, and Luther more Christian than Augustine. That is the hopeful feature in the past. The task for the present, with its unequalled scientific resources, is to get nearer than ever to the heart of the Gospel. Must Pauline categories always be supreme? The Ritschl school, and others too, have made an earnest effort to incorporate Christ's words in Dogmatic and no longer shunt them into systems of "Christian Ethics." They have not idolized Paulinism; but have they not idolized Luther? They seem to take for granted that the spirit—though not the letter—of that great man was a definitive statement of the Christian principle. To interpret Christianity out of itself is one thing; to interpret it out of Luther, even out of a distillate of Luther, is possibly a lower thing. The theology of the future may draw more equally from several New Testament types of doctrines. The scheme that includes most may be the successful scheme. Unity may be safeguarded in the confession of Christ, and theology indeed prove "Christocentric."[1] Above all, the social message of Jesus may well prove a gospel to our materially prosperous but inwardly sorrowful age. Any school of thought which despises that hope has small right to call itself Christian.

[1] Thomasius and H. B. Smith are quoted as holding the "Christocentric" ideal. A. M. Fairbairn, mindful of the vast importance of the conception of God, amends the programme. Theology is to be formally Christocentric, materially Theocentric (Fatherhood of God).

Natural and Revealed—the Logos. Casting a backward glance once more over the evolution of Christian theology, we may say very roughly that at first it recognized as natural or rational truth the being of the Logos, and as special fact of revelation the Incarnation of the Word in Jesus Christ. In medieval times the basis was altered. What had been rational truth now claimed acceptance as supernatural mystery. Modern idealists, ill at ease with this inheritance, try to show that Christ's Incarnation no less than His eternal divine being is a natural and rational truth. But, when this programme is carried out, there is no small danger lest the relations traced out between God and men should collapse into dust, the facts of Christ transform themselves into symbols, and the idealistic theology of the right wheel to the left.

The Atonement. Again, Western theology, very roughly summarized, while accepting the earlier doctrinal tradition, has broken new ground for itself, in affirming as rational necessity that God must punish sin (this is at least latent in Aquinas's doctrine of natural law), but as contingent fact of revelation that God has in Christ combined the punishment of sin with the salvation of sinners; this is the Reformation or post-Reformation thought. Here again the desire makes itself felt to impute more to God's nature. Is His mercy not as inherent as His justice? If so, *must* He not redeem? For, if He merely may redeem but must punish, then His greatest deeds on our behalf wear an aspect of caprice, or suggest unknown if not unknowable motives. The doctrine of penal substitution in the Atonement, as usually conceived, seems to point in the same direction as predestinarianism. Behind superficial manifestations of grace there is a dark background, almost like the Greek Fate. The ultimate source of God's actions is something either unintelligible or unrevealed. Christian theology cannot acquiesce in this. In our day especially it must seek to light up every doctrine with the genuine Christian belief in God's Fatherhood. And yet here again incautious advance may seem to overleap itself. If it should come to be held that with so kind a God no redemption at all is necessary, the significance of Christ is immensely curtailed if not blotted out. Even if He should still be taken as the prophet of the divine goodwill, yet the loss of any serious estimate of sin makes good nature on God's part a matter of course. Christianity of such a type is likely to be feeble and precarious. Perhaps we may find a third and better possibility by ceasing to aim at a scientific gnosis of God, either limited or unlimited. Perhaps what concerns the Christian is rather the assured revelation that God is acting in character, like Himself, and yet acting wonderfully by methods which we could not predict but must adore. The free life of personal beings is no more to be mastered by a formula than it is to be assigned to caprice. A God who is love will act neither from wilfulness nor from what is called rational but might more correctly be called physical necessity. He will act in and from character. Always wise, always holy, always unsearchable, the Christian's God is that heavenly Father who has His full image and revelation in Jesus Christ.

Modern divisions of theology. While the greatest of all theological systems, the *Summae* of the middle ages, include everything in the one treatise, it has been the business of post-Reformation learning to effect a formal improvement by distributing theological studies among a definite number of headings. The new theory lived and grew throughout the 18th-century Age of Enlightenment (*e.g.* J. S. Semler), linking Protestant scholasticism with modern thought, and exhibiting the continuity of science in spite of great revolutionary changes and great reactions. The beginning is ascribed to A. Hyperius (Gerhard of Yprès), a professor at Marburg, and, it seems, a conciliatory Lutheran, not, as sometimes said, a Reformed (1511–64). He published *Four Books on the Study of Theology* (1556). Book iv. is said to be the first appearance of Practical Theology—Liturgics, Pastoral Theology, &c. In virtue of another work (*De Formandis Concionibus*, 1553), Hyperius has been further termed the father of Homiletics. L. Danaeus (Daneau), a French Protestant, has the merit of publishing for the first time on *Christian Ethics* (1577). It has been supposed that the Reformed divinity here set itself to remedy the dogmatic dryness of Protestant scholasticism, fifty years before the Lutheran G. Calixtus moved in the matter (*Theol. Moralis*, 1634). Too much has been made of this. Danaeus hardly represents at all what moderns mean by Christian ethics. He does not contrast the Christian outlook upon ethics with all others, but dwells chiefly upon the super-eminence of the Ten Commandments as a summary of duty. Other distinctions are named after an interval of two centuries. J. T. Gabler, for the first time "with clearness" (R. Flint), wrote in 1787 *De Justo Discrimine Theologiae Biblicae et Dogmaticae.* Biblical Theology is a historical statement of the different Bible teachings, not a dogmatic statement of what the writer holds for truth, *qua* truth. Again, P. K. Marheineke is named as the first writer (1810) on Symbolics, the comparative study of creeds and confessions of faith. In 1764 the introductory study of theology as a whole, which Hyperius invented, had been given by S. Mursinna the name it has since usually borne—"Theological Encyclopaedia." Most of such Encyclopaedias have been "material," *i.e.* connected treatises, giving a brief outline of theology as a whole; not, of course, alphabetic indexes or dictionaries. The most famous of all, however—Schleiermacher's *Kurze Darstellung des theologischen Studiums* (1st ed. 1811)—belongs to the class of "formal" encyclopaedias. It states how theology should be divided, but does not profess to give a bird's-eye view of results.

Schleiermacher's treatise is highly individual. Theology is viewed as essentially a branch of church administration. True, in the theologian properly so called the scientific interest is strong; where the religious or practical interest is stronger, you get church rulers or administrators in a narrower sense. Still, even to the theologian the practical interest in church welfare is vital. Theology loses its savour when studied in a spirit of merely scientific curiosity; and it does not concern the lay Christian.

In spite of what may be deemed eccentric in this standpoint, Schleiermacher's summary is full of interest. He divides as follows:—I. Philosophical Theology: A. Apologetics; B. Polemics. II. Historical Theology: A. Exegetical—including the determination of the canon; B. Church History proper; C. The depicting of the present state of the Church; (1) its faith—Dogmatics; the belief of one branch of the Church; (2) its outward condition—Statistics; these should be universal. Symbolics is to be a branch of statistics. Biblical "Dogmatics" also is said to be nearer this than it is to Dogmatics proper. III. Practical Theology: A. the service of the (local) church; Homiletics, Liturgics, &c.; B. the *Government* of the (national or international) Church; questions of relation to the State, &c. The reader will note Schleiermacher's peculiar way of dealing with Dogmatic as the belief of the Church—an unprecedented view, according to A. Ritschl—and his requiring that belief to be reported *qua* historical fact.

It is singular that Schleiermacher on the whole sums up in the *Kurze Darstellung* against the separation of Christian Ethics from Dogmatics. But he grants that much may be said on both sides of that question, and in his own *Glaubenslehre* he follows ordinary usage and as far as possible banishes Ethics to a *Christliche Sittenlehre*, a book which has caused him to be regarded by Protestants as the founder of modern Christian Ethics. There are therefore three parallel studies, on all of which Schleiermacher published—Dogmatic or *Glaubenslehre*, Christian Ethics, Philosophical Ethics.

Curiously enough, it is from Schleiermacher's philosophical ethics that a threefold division—the Chief Good, Virtues, and Duty or the Law—passed into almost all text-books of Christian Ethics, till recently a rebellion rose against it on the ground of redundancy and overlapping. Books on Christian Ethics have also found room for a *quasi* Synoptic doctrine of the Kingdom of God, which Paulinized dogmatic systems were slow to admit. It should also be noted that Schleiermacher's place for Apologetics is by no means undisputed. Many dislike the subject; some would thrust it into practical theology. Again, the new study of the religions of the world is seeking its place in the curriculum of Christian theology, just as it is seeking—in some way—to modify Christian thought. The recognized place, the assured results, have not yet been attained

Further details must be sought in text-books. But it may be affirmed that Dogmatic must remain the vital centre; and so far we may soften Flint's censure of the British thoughtlessness which has called that study by the name "systematic theology." Systems of ethics and apologetics are welcome to the theologian; "encyclopaedia" is a new and broader-based "systematic theology" in itself; but none of these is central as Dogmatic is. One may also venture to declare that Dogmatic rests upon philosophical and historical studies, and exists for practical uses. Thus a triple or fourfold division of theological sciences seems natural. Lastly, it must be confessed that at the beginning of the 20th century there is more life or health in history than in philosophy, and much more in either than in dogmatic theology.

Some conclusions.

Sub-divisions of Dogmatic, whether well chosen or ill, throw light upon theology as developed in the past. The six usual Protestant headings are as follows: Theology proper, Anthropology, Christology (C. Hodge here inserts Hamartiology), Soteriology, Ecclesiology (omitted by C. Hodge), Eschatology. The Lombard's *Sentences* deal in bk. i. with God; bk. ii. the creatures; bk. iii. Incarnation, Redemption, Virtues; bk. iv. Sacraments and Last Things. Aquinas's *Summa* has no such clear lines of division.

The Church carried forward from the middle ages a tradition of "Moral Theology"[1] answering to Christian Ethics, alongside of Dogmatics or of all-inclusive *Summae.* Casuistry (with parallels in early Protestantism like Jeremy Taylor's *Ductor Dubitantium*), growing out of the Confessional, is characteristic of this Roman Catholic Ethic; yet the study is not restricted to the technical equipment of confessors. The Roman Catholic contributors to the volume on Christianity in *Die Kultur der Gegenwart* write on:—I. Dogmatic: A. Apologetic or General Dogmatic; B. Special Dogmatic or Dogmatic proper. II. Moral Theology. III. Practical Theology. The Protestant contributors, representing somewhat varied standpoints in German religion, follow much the same plan. Apologetic has no separate place with them; but the *system* of theology (in a sense midway between the dogmatists and the encyclopedists), is allotted between Dogmatics, Christian Ethics and Practical Theology.

LITERATURE.—A bibliography of theology cannot name every important book. The effort is made here (1) to mention writers of great originality and distinction, (2) writers of special importance to some one Christian confession, (3) without needless repetition of what has already been said, (4) dogmatic treatises being preferred but not to the exclusion of everything else.

Origen is great in scholarship as well as in system. Athanasius's *On the Incarnation of the Eternal Word* represents his central thoughts not less interestingly because it is earlier than the Arian controversy. Cyril of Jerusalem's *Catechetical Lectures* are a statement of doctrine for popular use, but arranged as a complete system. Gregory of Nyssa's *Great Catechesis* is an instruction to catechists how they should proceed—though of course stating the writer's theology and apologetic, with his belief in universal salvation. Theodoret has an outline of theology in the last book (v.) of his treatise *Against Heresies.* Theodore of Mopsuestia is a more suspected representative of the same scholarship—that of Antioch; John Chrysostom is the orator of the school. Cyril of Alexandria represents the later Alexandrian theology. With John of Damascus the progress of Greek divinity ends. A good modern statement is in Chr. Androntsos's Δογματική. In the West, Augustine is the chief agent in breaking new ground for theology. The *Enchiridion ad Laurentium* is a slight but interesting sketch of a system, while the *De Doctrina Christiana* is another lesson in the imparting of Christian instruction, as is also, naturally, the *De Catechizandis Rudibus.* The *City of God* and the *Confessions* are of unmatched importance in their several ways; and nothing of Augustine's was without influence. Gregory the Great's *Magna Moralia* should also be named.

In the middle ages Isidore (at its gateway), then Peter Lombard, then Aquinas (and his rivals), are pre-eminent for system, Anselm and Abelard for originality, Bernard of Clairvaux as the theologian who represents medieval piety at its purest and in its most characteristic forms, while Thomas à Kempis's devotional masterpiece, *On the Imitation of Christ*, with Tauler's *Sermons* and the *Theologia Germanica*, belong to the world's classics. All the Protestant reformers are of theological importance—Luther, Melanchthon and

[1] "Mystical Theology" is described in Addis and Arnold's *Catholic Dictionary* as a "branch" of Moral Theology.

Calvin, then Zwingli, then John Knox and others. The reply to Protestantism is represented by Cardinal Bellarmine, Petavius (less directly), Moehler.

Speculative theology was represented in the Roman Catholic Church of the 19th century by the Italian writers A. Rosmini, V. Gioberti, T. Mamiani della Rovere. Roman Catholic learning has always taken a high place (the Bollandists; the Benedictines; the huge collections of Migne). Of the Church's ample devotional literature St Francis of Sales and F. W. Faber are favourable specimens. A modern *Dogmatic* is by Syl. T. Hunter, S.J.

Anglican theology is little inclined to dogmatics. We have such unsystematic systems as Bishop Pearson's *Exposition* of the Apostles' Creed—a book of the golden age of great writers—or we have average 19th-century Church orthodoxy in Bishop H. Browne, *On the XXXIX. Articles*. Anglicanism prefers to philosophize institutions (R. Hooker, *Laws of Ecclesiastical Polity*), or states ancient learning (R. Cudworth; the Cambridge Platonists), or else polemical learning—Bishop Bull (against Petavius's innovating views of history), D. Waterland (against S. Clarke), S. Horsley (against J. Priestley), J. B. Lightfoot (very strong as an apologist in scholarship; not strong in pure thinking); the polemic becomes altogether conciliatory in those other glories of 19th-century Cambridge, B. F. Westcott and F. J. A. Hort. Or Anglican theology deals with historical points of detail, such as fill the *Journal of Theol. Studies*. In devotional literature Anglicanism has always been rich (*e.g.* Jeremy Taylor, Archbishop R. Leighton, L. Andrewes, W. Law, J. H. Newman). Bishop Butler stands by himself in lonely greatness.

English Puritanism lives in the affections of modern readers more than the Protestant schoolmen of the Continent do—Richard Baxter, John Owen, John Howe, Thos. Goodwin, John Goodwin (an early Arminian); for learning, John Lightfoot; for genius, John Milton; for literary and devotional power, John Bunyan—always admirable except when he talks Puritan dogma. Essential Puritanism is prolonged in the 19th century by R. W. Dale (*The Atonement; Christian Doctrine*). The Scottish leader, T. Chalmers (*Lectures on Divinity*), is more important as an orator or as a man than as a thinker. The somewhat earlier lectures of G. Hill are dry.

Arminianism is less fully worked out by Arminius than by later Dutch divines, of whom the "conciliatory" Limborch is sometimes used as a Methodist text-book. The theologian of English Methodism, apart from John Wesley himself, is Richard Watson. W. B. Pope's *Compendium* is a somewhat more modern version.

Jonathan Edwards, a very stern Calvinist, is one of the few first-rate geniuses America has to boast in theology. C. Hodge, A. A. Hodge, W. G. T. Shedd, published Calvinistic systems. Horace Bushnell had great influence.

While the production of systems of Dogmatic (and of Christian Ethics) never ceases in Germany, A. Ritschl was content to rely on his treatise upon *Justification and Reconciliation* (vol. i. History of the Doctrine; ii. Biblical material; iii. Positive construction—but much intermingled with history; good English translations of i. and iii.). His *Unterricht in der Christlichen Religion* is poor as a school-book but useful for reference. Something is to be learned regarding Ritschl himself from his very hostile *Hist. of Pietism*. The earlier *Entstehung der altkatholischen Kirche* (2nd ed. 1857) is a landmark in Apologetics and Church history. J. Kaftan's *Dogmatic* should be named, also the *Modern Positive Theology* of Th. Kaftan and others.

H. L. Martensen's *Dogmatics* restates substantial orthodoxy with fine literary taste. His *Christian Ethics*, though diffuse, is perhaps the finest piece of Protestant theology under that title. His friend, I. A. Dorner, had a powerful mind but an inferior gift of style.

The student of theology will do well to seek in the best histories of doctrine more detached treatment than Dogmatic can give. F. Loofs mentions W. Münscher, J. A. W. Neander, F. C. Baur, G. Thomasius, F. Nitzsch, A. Harnack, as showing steady advance. Add Loofs himself and R. Seeberg. Works in English by W. G. T. Shedd, G. P. Fisher, J. F. Bethune Baker. Church formularies in Winer (*Confessions of Christendom*), Schaff (*Creeds of Christendom*), F. Loofs (*Symbolik*). The *Symbolik* of J. A. Moehler is a very able anti-Protestant polemic.

A German reviewer has associated as English contributions to Dogmatics, A. M. Fairbairn's *Christ in Modern Theology*, A. B. Bruce's *Apologetics*, and the present writer's *Essay towards a New Theology*. Two American books represent modern evangelicalism—W. N. Clarke's very successful *Outline of Theology*, and W. A. Brown's *Christian Theology in Outline*. The High Church position is given in the *Manual* of T. B. Strong, Evangelical Anglicanism in H. G. C. Moule's *Outline*.

Encyclopaedia may be studied in J. F. Räbiger, translated with additions by J. Macpherson. J. Drummond (Unitarian) and A. Cave (Congregationalist) have written *Introductions to Theology*; Cave's bibliographies are not free from errors. American contributions in P. Schaff's *Propaedeutic* and J. F. Hurst's *Literature of Theology; a Classified Bibliography*. Recent German work by C. F. G. Heinrici; for older treatment see C. R. Hagenbach.

(R. Ma.)

THEON, AELIUS, Alexandrian sophist of uncertain date, author of a collection of preliminary exercises (*pro-gymnasmata*) for the training of orators. The work (extant, though incomplete), which probably formed an appendix to a manual of rhetoric, shows learning and taste, and contains valuable notices on the style and speeches of the masters of Attic oratory. Theon also wrote commentaries on Xenophon, Isocrates and Demosthenes, and treatises on style. He is to be distinguished from the Stoic Theon, who lived in the time of Augustus and also wrote on rhetoric (Quintilian, *Inst. Orat.* ix. 3, 77).

THEON, of Samos, Greek painter of the age of Alexander the Great, is mentioned by Quintilian as a good artist of the second rank. If we may trust the somewhat flimsy stories told about him, his forte consisted in a lifelike, or perhaps, as Brunn (*Künstlergeschichte*, ii. 253) puts it, a theatrical representation of action. His figures were said to start out of the picture. He chose such congenial subjects as the madness of Orestes, and a soldier rushing to battle. Another painter, Theorus, is mentioned, whom Brunn regards as identical with Theon.

THEOPHANES, surnamed "the Confessor" (*c.* A.D. 758–817), Greek ascetic, chronicler and saint, belonged to a noble and wealthy family, and held several offices under Constantine V. Copronymus (741–775). He subsequently retired from the world and founded a monastery (τοῦ Μεγάλου Ἀγροῦ) near Sigriane.[1] He was a strong supporter of the worship of images, and in 815 was summoned to Constantinople by Leo the Armenian, who formally ordered him to renounce his principles. Theophanes refused, and, after two years' imprisonment, was banished to the island of Samothrace, where he died. He subsequently received the honours of canonization. At the request of his dying friend, George the Syncellus (*q.v.*), Theophanes undertook to continue his *Chronicle*, which he carried on from the accession of Diocletian to the downfall of Michael I. Rhangabes (284–813). The work, although wanting in critical insight and chronological accuracy, is of great value as supplying the accounts of lost authorities. The language occupies a place midway between the stiff ecclesiastical and the vulgar Greek. In chronology, in addition to reckoning by the years of the world and the Christian era, Theophanes introduces in tabular form the regnal years of the Roman emperors, of the Persian kings and Arab caliphs, and of the five oecumenical patriarchs, a system which leads to considerable confusion. The *Chronicle* was much used by succeeding chroniclers, and in 873–875 a compilation in barbarous Latin (in vol. ii. of De Boor's edition) was made by the papal librarian Anastasius from Nicephorus, George the Syncellus, and Theophanes for the use of a deacon named Johannes. The translation (or rather paraphrase) of Theophanes really begins with the reign of Justin II. (565), the excerpts from the earlier portion being scanty. At that time there were very few good Greek scholars in the West, and Anastasius shows himself no exception.

There is also extant a further continuation, in six books, of the *Chronicle* down to the year 961 by a number of mostly anonymous writers (called Οἱ μετὰ Θεοφάνην, Scriptores post Theophanem), who undertook the work by the instructions of Constantine Porphyrogenitus.

Editions of the *Chronicle:—Editio princeps*, J. Goar (1655); J. P. Migne, *Patrologia Graeca*, cviii.; J. Classen in Bonn *Corpus Scriptorum Hist. Byzantinae* (1839–41); and C. de Boor (1883–85), with an exhaustive treatise on the MS. and an elaborate index; see also the monograph by J. Pargoire, "Saint Théophane le Chronographe et ses rapports avec saint Théodore studite," in Βυζαντινὰ Χρονικά, ix. (St Petersburg, 1902).

Editions of the *Continuation* in J. P. Migne, *Patr. Gr.*, cix., and by I. Bekker, Bonn *Corpus Scriptorum Hist. Byz.* (1838); on both works and Theophanes generally, see C. Krumbacher, *Geschichte der byzantinischen Litteratur* (1897); *Ein Dithyrambus auf Theophanes Confessor* (a panegyric on Theophanes by a certain *protoasecretis*, or chief secretary, under Constantine Porphyrogenitus) and *Eine neue Vita des Theophanes Confessor* (anonymous), both edited by the same writer in *Sitzungsberichte der philos.-philol. und*

[1] Near the village of Kurshunla, on the Sea of Marmora, between the site of the ancient Cyzicus and the mouth of the Rhyndacus, ruins of the monastery may still be seen; on the whole question see J. Pargoire's monograph, section 6 (see Bibliography).

der hist. Cl. der k. bayer. Akad. der Wissenschaften (1896, pp. 583–625; and 1897, pp. 371–399); Gibbon's *Decline and Fall* (ed. Bury), v. p. 500.

THEOPHANO (*c.* 956–991), wife of the Roman emperor Otto II., was a daughter of the Eastern emperor Romanus II., and passed her early years amid the tragic and changing fortunes which beset the court of Constantinople. Otto the Great having procured her betrothal to his son Otto II., she was married to him and crowned empress at Rome by Pope John XIII. on the 14th of April 972. In return for costly gifts brought by her to her husband, she was granted extensive estates in all parts of the empire. She appears to have been a woman of great beauty and considerable intelligence, and after the death of Otto the Great in 973 gradually superseded his widow Adelaide as the chief adviser of the new emperor, whom she accompanied on several military expeditions. She introduced many Byzantine customs into the German court. After the death of Otto in December 983 she returned to Germany, which she governed with conspicuous success in the name of her son, Otto III. In 989 she visited Rome, where she exercised as *imperatrix* the imperial prerogatives, and probably compelled the Romans to swear to acknowledge her son. Theophano died at Nimwegen on the 15th of June 991, and was buried in the church of St Pantaléon at Cologne.

See J. Moltmann, *Theophano, die Gemahlin Ottos II. in ihrer Bedeutung für die Politik Ottos I. und Ottos II.* (Göttingen, 1878).

THÉOPHILE, the name by which Théophile de Viau (or Viaud), French poet (1591–1626), is more commonly called. He was born in 1591, at Clairac, near Agen, and spent his early years at Boussères de Mazères, his father's property. He was educated at the Protestant college of Saumur, and he went to Paris in his twentieth year. In 1612 he met Balzac, with whom he made an expedition to the Netherlands, which ended in a serious quarrel. On his return he seems to have been for two years a regular playwright to the actors at the Hôtel de Bourgogne. In 1615 he attached himself to the ill-fated Henry, duke of Montmorency (1595–1632), under whose protection he produced with success the tragedy of *Pyrame et Thisbé*, acted probably about 1617 and printed in 1623, although placed later by some critics. This piece, written in the extravagant Spanish-Italian manner, which was fashionable in the interval between the Pléiade model and the innovations of Corneille, was ridiculed by Boileau (Preface to his *Œuvres*, 1701). Théophile was the acknowledged leader of a set of Parisian libertines, whose excesses seem to have been chiefly dictated by a general hatred of restraint. He himself was not only a Huguenot, but a free-thinker, and had made unsparing use of his sharp wit in epigrams on the Church and on the government. In 1619 he was accused of blasphemous and indecent writings, and was banished from Paris. He took refuge in the south of France, where he found protection with many friends. He was allowed to return in the next year, and effected a partial reconciliation with one of his most powerful enemies, the duc de Luynes. He served in that year in the campaign against the Huguenots, but in the autumn was again in exile, this time in England. He was recalled in 1621, and began to be instructed in the Roman Catholic religion, though his abjuration of Protestantism was deferred until the end of 1622. There is nothing to show that this conversion was purely political; in any case it did little to mollify his enemies. In 1622 he had contributed four pieces to the *Nouveau Parnasse Satirique*, a miscellany of verse by many hands. In the next year a new edition appeared, with the addition of some licentious verse, and the inscription *par le sieur Théophile* on the title-page. Contemporary opinion justified Théophile's denial of this ascription, but the Jesuit father, François Garasse, published a tract against him entitled *La Doctrine curieuse* (1623). Théophile was again prosecuted. This time he fled from Paris, to the court of Montmorency, and was condemned in his absence (19th of August 1623) to death. On his flight to the border he was arrested, and imprisoned in the Conciergerie in Paris. He defended himself in an *Apologie au roi* (1625), and was liberated in September, his sentence being commuted to banishment for life. Under Montmorency's protection he was able to hide in Paris for some time, and he subsequently accompanied his friend and patron to the south. He died in Paris on the 25th of September 1626.

The great interest aroused by the prosecution and defence of Théophile is shown by the number of pamphlets on the subject, forty-two of which, written between the dates 1622 and 1626, are preserved in the Bibliothèque Nationale in Paris.

Les Œuvres du Sieur Théophile were printed in Paris in 1621, and other collections followed during his lifetime. Six years after his death Georges de Scudéry edited his work with a *Tombeau* (copy of obituary verses), and a challenge in the preface to any one who might be offended by the editor's eulogy of the poet. A tragedy entitled *Pasiphae*, published in 1631, is probably not Théophile's, and is not included in his works, the standard modern edition of which is that of Alleaume in the *Bibliothèque Elzévirienne* (2 vols. 1856). Besides *Pyrame et Thisbé*, his works include a paraphrase, half verse, half prose, of the *Phaedo*. There are numerous French and Latin letters, his *Apologie*, a promising fragment of comic prose narrative, and a large collection of occasional verses, odes, elegies, stanzas, &c.

In addition to Alleaume's edition, a delightful article in Théophile Gautier's *Grotesques* should be consulted respecting him. A full account of the extensive literature dealing with Théophile is given by Dr K. Schirmacher in a study on *Théophile de Viau* (Leipzig and Paris, 1897). In the *Page disgracié* of Tristan l'Hermite, the page makes the acquaintance of a dramatic author, and his description may be accepted as a contemporary portrait of Théophile's vigorous personality.

THEOPHILUS, East Roman emperor (829–842), the second of the "Phrygian" dynasty. Unlike his father Michael II., he declared himself a pronounced iconoclast. In 832 he issued an edict strictly forbidding the worship of images; but the stories of his cruel treatment of recalcitrants are probably exaggerated. At the time of his accession, the Sicilians were still engaged in hostilities with the Saracens, but Theophilus was obliged to devote all his energies to the war against the caliphs of Bagdad (see CALIPHATE, especially sect. C., § 8). This war was caused by Theophilus, who afforded an asylum to a number of Persian refugees, one of whom, called Theophobus after his conversion to Christianity, married the emperor's sister Helena, and became one of his generals. The Roman arms were at first successful; in 837 Samosata and Zapetra (Zibatra, Sozopetra), the birthplace of Motasim, were taken and destroyed. Eager for revenge, Motasim assembled a vast army, one division of which defeated Theophilus, who commanded in person, at Dasymon, while the other advanced against Amorium, the cradle of the Phrygian dynasty. After a brave resistance of fifty-five days, the city fell into Motasim's hands through treachery (23rd of September 838). Thirty thousand of the inhabitants were slain, the rest sold as slaves, and the city razed to the ground. Theophilus never recovered from the blow, his health gradually failed, and he died at the beginning of 842. His character has been the subject of considerable discussion, some regarding him as one of the ablest of the Byzantine emperors, others as an ordinary oriental despot, an overrated and insignificant ruler. There is no doubt that he did his best to check corruption and oppression on the part of his officials, and administered justice with strict impartiality, although his punishments did not always fit the crime. In spite of the drain of the war in Asia and the large sums spent by Theophilus on building, commerce, industry, and the finances of the empire were in a most flourishing condition, the credit of which was in great measure due to the highly efficient administration of the department. Theophilus, who had received an excellent education from John Hylilas, the grammarian, was a great admirer of music and a lover of art, although his taste was not of the highest. He strengthened the walls of Constantinople, and built a hospital, which continued in existence till the latest times of the Byzantine Empire.

Finlay, *History of Greece*, ii. (1877) p. 142; G. F. Hertzberg, *Geschichte der Byzantiner und des osmanischen Reiches*, bk. i. (Berlin, 1883); H. Gelzer, "Abriss der byzantinischen Kaisergeschichte" in C. Krumbacher's *Geschichte der byzantinischen Litteratur* (2nd ed.

1897); and authorities under ROMAN EMPIRE, LATER. On the early campaigns against the Arabs see J. B. Bury, in *Journ. Hell. Stud.* xxix., 1909, pt. i.

THEOPHRASTUS, the successor of Aristotle in the Peripatetic school, a native of Eresus in Lesbos, was born *c.* 372 B.C. His original name was Tyrtamus, but he later became known by the nickname "Theophrastus," given to him, it is said, by Aristotle to indicate the grace of his conversation. After receiving his first introduction to philosophy in Lesbos from one Leucippus or Alcippus, he proceeded to Athens, and became a member of the Platonic circle. After Plato's death he attached himself to Aristotle, and in all probability accompanied him to Stagira. The intimate friendship of Theophrastus with Callisthenes, the fellow-pupil of Alexander the Great, the mention made in his will of an estate belonging to him at Stagira, and the repeated notices of the town and its museum in the *History of Plants*, are facts which point to this conclusion. Aristotle in his will made him guardian of his children, bequeathed to him his library and the originals of his works, and designated him as his successor at the Lyceum on his own removal to Chalcis. Eudemus of Rhodes also had some claims to this position, and Aristoxenus is said to have resented Aristotle's choice. Theophrastus presided over the Peripatetic school for thirty-five years, and died in 287 B.C. Under his guidance the school flourished greatly—there were at one period more than 2000 students—and at his death he bequeathed to it his garden with house and colonnades as a permanent seat of instruction. Menander was among his pupils. His popularity was shown in the regard paid to him by Philip, Cassander and Ptolemy, and by the complete failure of a charge of impiety brought against him. He was honoured with a public funeral, and "the whole population of Athens, honouring him greatly, followed him to the grave" (Diog. Laërt.).

From the lists of the ancients it appears that the activity of Theophrastus extended over the whole field of contemporary knowledge. His writing probably differed little from the Aristotelian treatment of the same themes, though supplementary in details (see PERIPATETICS). He served his age mainly as a great popularizer of science. The most important of his books are two large botanical treatises, *On the History of Plants*, in nine books (originally ten), and *On the Causes of Plants*, in six books (originally eight), which constitute the most important contribution to botanical science during antiquity and the middle ages. We also possess in fragments a *History of Physics*, a treatise *On Stones*, and a work *On Sensation*, and certain metaphysical Ἀπορίαι, which probably once formed part of a systematic treatise. Various smaller scientific fragments have been collected in the editions of J. G. Schneider (1818–21) and F. Wimmer (1842–62) and in Usener's *Analecta Theophrastea*.

The *Ethical Characters* (Ἠθικοὶ χαρακτῆρες) deserves a separate mention. The work consists of brief, vigorous and trenchant delineations of moral types, which contain a most valuable picture of the life of his time. They form the first recorded attempt at systematic character writing. The book has been regarded by some as an independent work; others incline to the view that the sketches were written from time to time by Theophrastus, and collected and edited after his death; others, again, regard the *Characters* as part of a larger systematic work, but the style of the book is against this. Theophrastus has found many imitators in this kind of writing, notably Hall (1608), Sir Thomas Overbury (1614–16), Bishop Earle (1628) and La Bruyère (1688), who also translated the *Characters*.

BIBLIOGRAPHY.—A good account of Theophrastus is found in Zeller, *Aristotle and the Earlier Peripatetics* (Eng. trans. by B. F. C. Costelloe and J. H. Muirhead, vol. ii., chap. 18, 1897). For his astronomical work see ASTRONOMY (Historical Section), and for the botanical works, see Dr J. Berendes, *Die Pharmacie bei den alten Culturvölken* (vol. i., 1891). The *Ethical Characters* was edited by Casaubon in 1592 and translated by La Bruyère (1688–89); the best modern translation (with introduction and notes) is that of Sir R. C. Jebb (1870; new ed. J. E. Sandys, 1909); recent editions are that of J. M. Edmonds and G. E. V. Austen (1904), containing text, notes and illustrations (intended for schools), and that of C. E. Bennett and W. A. Hammond (1902), a translation, with an introduction. The work has been translated into nearly all European languages (see Baldwin's *Dict. of Philos. and Psych.*, vol. iii. pt. i.). (E. WH.)

THEOPHYLACT (d. *c.* 1110), biblical commentator, was born most probably at Euripus, in Euboea, about the middle of the 11th century. He became a deacon at Constantinople, attained a high reputation as a scholar, and became the tutor of Constantine Porphyrogenitus, son of the Emperor Michael VII., for whom he wrote *The Education of Princes* (Παιδεία βασιλική). About 1078 he went into Bulgaria as archbishop of Achrida. In his letters he complains much of the rude manners of the Bulgarians, and he sought to be relieved of his office, but apparently without success. His death took place after 1107.

His commentaries on the Gospels, Acts, the Pauline epistles and the Minor Prophets are founded on those of Chrysostom, but deserve the considerable place they hold in exegetical literature for their appositeness, sobriety, accuracy and judiciousness. His other extant works include 130 letters and various homilies and orations and other minor pieces. A careful edition of nearly all his writings, in Greek and Latin, with a preliminary dissertation, was published in 1754–63 by J. F. B. M. de Rossi (4 vols. fol., Venice).

See Krumbacher, *Byzantinische Litteraturgeschichte* (2nd ed. 1897), pp. 132, 463.

THEOPOMPUS (b. *c.* 380), Greek historian and rhetorician, was born at Chios about 380 B.C. In early youth he seems to have spent some time at Athens, along with his father, who had been exiled on accouut of his Laconian sympathies. Here he became a pupil of Isocrates, and rapidly made great progress in rhetoric; we are told that Isocrates used to say that Ephorus required the spur but Theopompus the bit (Cicero, *Brutus*, 204). At first he appears to have composed epideictic speeches, in which he attained to such proficiency that in 352–351 he gained the prize of oratory given by Artemisia (*q.v.*) in honour of her husband, although Isocrates was himself among the competitors. It is said to have been the advice of his teacher that finally determined his career as an historian—a career for which he was peculiarly qualified owing to his abundant patrimony and his wide knowledge of men and places. Through the influence of Alexander, he was restored to Chios about 333, and figured for some time as one of the leaders of the aristocratic party in his native town. After Alexander's death he was again expelled, and took refuge with Ptolemy in Egypt, where he appears to have met with a somewhat cold reception. The date of his death is unknown.

The works of Theopompus were chiefly historical, and are much quoted by later writers. They included an *Epitome of Herodotus's History* (the genuineness of which is doubted), the *Hellenics* (Ἑλληνικά, Ἑλληνικαὶ ἱστορίαι), the *History of Philip* (Φιλιππικά), and several panegyrics and hortatory addresses, the chief of which was the *Letter to Alexander*. The *Hellenics* treated of the history of Greece, in twelve books, from 411 (where Thucydides breaks off) to 394—the date of the battle of Cnidus (cf. Diod. Sic., xiii. 42, with xiv. 84). Of this work only a few fragments were known up till 1907. The papyrus fragment of a Greek historian of the 4th century B.C., discovered by B. P. Grenfell and A. S. Hunt, and published by them in *Oxyrhynchus Papyri*, vol. v. (1908), has been recognized by Ed. Meyer, U. von Wilamowitz-Moellendorff and G. Busolt as a portion of the *Hellenics*. This identification has been disputed, however, by F. Blass, J. B. Bury, E. M. Walker and others, most of whom attribute the fragment, which deals with the events of the year 395 B.C. and is of considerable extent, to Cratippus (*q.v.*). A far more elaborate work was the Φιλιππικά in 58 books. In this Theopompus narrated the history of Philip's reign (360–336), with digressions on the names and customs of the various races and countries of which he had occasion to speak, which were so numerous that Philip V. of Macedon reduced the bulk of the history from 58 to 16 books by cutting out those parts which had no connexion with Macedonia. It was from this history that Trogus Pompeius (of whose *Historiae Philippicae* we possess the epitome by Justin) derived much of his material. Fifty-three books were extant in the time of Photius (9th century), who read them, and has left us an epitome of the 12th book. Several fragments, chiefly anecdotes and strictures of various kinds upon the character of nations and individuals, are preserved by Athenaeus, Plutarch and others. Of the *Letter to Alexander* we possess one or two fragments cited by Athenaeus, animadverting severely upon the immorality and dissipations of Harpalus. The *Attack upon Plato*, and the treatise *On Piety*, which are sometimes referred to as separate works, were perhaps only two of the many digressions in the history of Philip; some writers have doubted their authenticity. The libellous attack (Τρικάρανος, the "three-headed") on the three cities—Athens, Sparta and Thebes—was published under the name of Theopompus by his enemy Anaximenes of Lampsacus. The nature of the extant fragments fully bears out the divergent criticisms of antiquity upon Theopompus. Their style is clear and pure, full of choice and pointed expressions, but lacking in weight and dignity. The artistic unity of his work suffered severely from the frequent and lengthy digressions already referred to. The most important was that *On the Athenian Demagogues* in the 10th book of the *Philippica*, containing a bitter attack on many of the chief Athenian statesmen, and generally recognized as having been freely used by Plutarch in several of the *Lives*. Another fault of Theopompus was his excessive fondness for romantic and incredible stories; a collection of some of these (Θαυμάσια) was afterwards made and published under his name. He was also severely blamed in antiquity for his censoriousness, and throughout his fragments no feature is more striking than this. On the whole, however, he appears to have been fairly impartial. Philip himself he censures severely for drunkenness and immorality, while Demosthenes receives his warm praise.

Bibliography.—Fragments in C. Müller, *Frag. Hist. Graec.*, i.; monograph by A. J. Pflugk (1827), and a good account in W. Mure, *Language and Literature of Ancient Greece*, v. pp. 509–529. See also Greece: *Ancient History*, § Authorities. A complete edition of the fragments of Theopompus and of Cratippus has been published by the Clarendon Press, Oxford (1909), containing the fragment of the new historian. For a discussion of the authorship of this fragment see *Oxyrhynchus Papyri* (1908), vol. v. pp. 110–242; G. Busolt, *Hermes* (1908), pp. 255–285 (*Der Neue Historiker und Xenophon*); E. M. Walker, *Klio* (1908) ("Cratippus or Theopompus"); W. A. W.)

THEORBO [Fr. *théorbe*, Ger. *Theorba*, Ital. *theorba*, Barbitone], the large double-necked bass lute much used during the 16th and 17th centuries as general bass in the orchestra. The body of the theorbo was constructed on the same principles as that of the lute but larger, and the same scheme of decoration was followed. The neck, instead of being bent back at an angle to form the head, was straight, having sufficient pegs set in the sides of the head for from 12 to 16 strings tuned in pairs of unisons; on the fingerboards were marked 8 or more frets for semitones. Above this neck was another without frets, curving forwards and slightly to one side to enable the long bass strings, stretched not over but at the side of the neck, to escape the pegs of the shorter strings. These free strings, known as diapason strings (Ger. *Begleitseiten*) were plucked *à vide* like those of the lyre, each giving but one note; the number of these strings varied from 8 to 11.

The theorbo was made in two sizes, the ordinary instrument measuring about 3 ft. 6 in., and the Paduan, also known as archlute, about 5 ft. The chitarrone, or Roman theorbo, was the largest of all, a contrabass lute in fact, and frequently stood over 6 ft. high. It differed slightly from the theorbo; the body was a little smaller than in the Paduan variety, the whole of the extra length being in the second neck. The strings over the fingerboard were of steel or brass, and the diapason strings of spun wire.

For the history of the theorbo, see Barbiton and Lute.

THEOSOPHY (from Gr. θεός, god, and σοφία, wisdom), a term used to denote those forms of philosophic and religious thought which claim a special insight into the Divine nature and its constitutive moments or processes. Sometimes this insight is claimed as the result of the operation of some higher faculty or some supernatural revelation to the individual; in other instances the theosophical theory is not based upon any special illumination, but is simply put forward as the deepest speculative wisdom of its author. But in any case it is characteristic of theosophy that it starts with an explication of the Divine essence, and endeavours to deduce the phenomenal universe from the play of forces within the Divine nature itself.

General Theory.—Theosophy is thus differentiated at once from all philosophic systems which attempt to rise from an analysis of phenomena to a knowledge, more or less adequate, of the existence and nature of God. In all such systems, God is the *terminus ad quem*, a direct knowledge of whom is not claimed, but who is, as it were, the hypothesis adopted, with varying degrees of certainty in different thinkers, for the explanation of the facts before them. The theosophist, on the other hand, is most at his ease when moving within the circle of the Divine essence, into which he seems to claim absolute insight. This, however, would be insufficient to distinguish theosophy from those systems of philosophy which are sometimes called "speculative" and "absolute," and which also in many cases proceed deductively from the idea of God.

In a wide sense, the system of Hegel or the system of Spinoza may be cited as examples of what is meant. Both thinkers claim to exhibit the universe as the evolution of the Divine nature. They must believe, therefore, that they have grasped the inmost principles of that nature: so much is involved, indeed, in the construction of an absolute system. But it is to be noted that, though there is much talk of God in such systems, the known universe—the world that now is—is nowhere transcended; God is really no more than the principle of unity immanent in the whole. Hence, while the accusation of pantheism is frequently brought against these thinkers, the term theosophical is never used in their regard. A theosophical system may also be pantheistic, in tendency if not in intention; but the transcendent character of its Godhead definitely distinguishes it from the speculative philosophies which might otherwise seem to fall under the same definition. God is regarded as the transcendent source of being and purity, from which the individual in his natural state is alienated and afar off. An historical survey shows, indeed, that theosophy generally arises in connexion with religious needs, and is the expression of religious convictions or aspirations. Accepting the testimony of religion that the present world lies in wickedness and imperfection, theosophy faces the problem of speculatively accounting for this state of things from the nature of the Godhead itself. It is thus in some sort a mystical philosophy of the existence of evil; or at least it assumes this form in some of its most typical representatives.

The term Mysticism (*q.v.*) has properly a practical rather than a speculative reference; but it is currently applied so as to include the systems of thought on which practical mysticism was based. Thus, to take only one prominent example, the profound speculations of Meister Eckhart (*q.v.*) are always treated under the head of Mysticism, but they might with equal right appear under the rubric Theosophy. In other words, while an emotional and practical mysticism may exist without attempting philosophically to explain itself, speculative mysticism is almost another name for theosophy. There is still a certain difference observable, however, in so far as the speculative mystic remains primarily concerned with the theory of the soul's relation to God, while the theosophist gives his thoughts a wider scope, and frequently devotes himself to the elaboration of a fantastic philosophy of nature.

In the above acceptation of the term, the Neoplatonic doctrine of emanations from the supra-essential One, the fanciful emanation-doctrine of some of the Gnostics (the aeons of the Valentinian system might be mentioned), and the elaborate esoteric system of the Kabbalah, to which the two former in all probability largely contributed, are generally included under the head of theosophy. In the two latter instances there may be noted the allegorical interpretation of traditional doctrines and sacred writings which is a common characteristic of theosophical writers. Still more typical examples of theosophy are furnished by the mystical system of Meister Eckhart and the doctrine of Jacob Boehme (*q.v.*), who is known as "the theosophist" *par excellence*. Eckhart's doctrine asserts behind God a predicateless Godhead, which, though unknowable not only to man but also to itself, is, as it were, the essence or potentiality of all things. From it proceed, and in it, as their nature, exist, the three persons of the Trinity, conceived as stadia of an eternal self-revealing process. The eternal generation of the Son is equivalent to the eternal creation of the world. But the sensuous and phenomenal, as such, so far as they seem to imply independence of God, are mere privation and nothingness; things exist only through the presence of God in them, and the goal of creation, like its outset, is the repose of the Godhead. The soul of man, which as a microcosmos resumes the nature of things, strives by self-abnegation or self-annihilation to attain this unspeakable reunion (which Eckhart calls being buried in God). Regarding evil simply as privation, Eckhart does not make it the pivot of his thought, as was afterwards done by Boehme; but his notion of the Godhead as a dark and formless essence is a favourite thesis of theosophy.

Besides mystical theology, Boehme was indebted to the writings of Paracelsus. This circumstance is not accidental, but points to an affinity in thought. The nature-philosophers of the Renaissance, such as Nicolaus Cusanus, Paracelsus, Cardan and others, curiously blend scientific ideas with speculative notions derived from scholastic theology, from Neoplatonism and even from the Kabbalah. Hence it is customary to speak of their theories as a mixture of theosophy and physics, or theosophy and chemistry, as the case may be. Boehme offers us a natural philosophy of the same sort. As Boehme is the typical theosophist, and as modern theosophy has nourished itself almost in every case upon the study of his works, his dominating conceptions supply us with the best illustration of the general trend of this mode of thought. His speculation turns, as has been said, upon the necessity of reconciling the existence and the might of evil with the existence of an all-embracing and all-powerful God, without falling into Manichaeanism on the one hand, or, on the other, into a naturalistic pantheism that denies the reality of the distinction between good and evil. He faces the difficulty boldly, and the eternal conflict between the two may be said to furnish him with the principle of his philosophy. It is in this connexion that he insists on the necessity of the Nay to the Yea, of the negative to the positive. Eckhart's Godhead appears in Boehme as the abyss, the eternal nothing, the essenceless quiet ("Ungrund" and "Stille ohne Wesen" are two of Boehme's phrases). But, if this were all, the Divine Being would remain an abyss dark even to itself. In God, however, as the condition of His manifestation, lies, according to Boehme, the "eternal nature" or the *mysterium magnum*, which is as anger to love, as darkness to light, and, in general, as the negative to the positive. This principle (which Boehme often calls the evil in God) illuminates both sides of the antithesis, and thus contains the possibility of their real existence. By the "Qual" or torture, as it were, of this diremption, the universe has qualitative existence, and is knowable. Even the three persons of the Trinity, though existing *idealiter* beforehand, attain reality only through this principle of nature in God, which is hence spoken of as their *matrix*. It forms also the matter, as it were, out of which the world is created; without the dark and fiery principle, we are told, there would be no creature. Hence God is sometimes spoken of as the father, and the eternal nature as the mother, of things. Creation (which is conceived as an eternal process) begins with the creation of the angels. The subsequent fall of Lucifer is explained as his surrender of himself to the principle of nature, instead of dwelling in the heart of God. He sought to make anger predominate over love; and he had his will, becoming prince of hell, the kingdom of God's anger, which still remains, however, an integral part of the Divine universe. It is useless to follow Boehme further, for his cosmogony is disfigured by a wild Paracelsian symbolism, and his constructive efforts in general are full of the uncouth straining of an untrained writer. In spite of these defects, his speculations have exercised a remarkable influence.

Schelling's *Philosophical Inquiries into the Nature of Human Freedom* (1809) is almost entirely a reproduction of Boehme's ideas, and forms, along with Baader's writings, the best modern example of theosophical speculation. In his philosophy of identity Schelling (*q.v.*) had already defined the Absolute as pure indifference, or the identity of subject and object, but without advancing further into theogony. He now proceeded to distinguish three moments in God, the first of which is the pure indifference which, in a sense, precedes all existence—the primal basis or abyss, as he calls it, in agreement with Boehme. But, as there is nothing before or besides God, God must have the ground or cause of His existence in Himself. This is the second moment, called nature in God, distinguishable from God, but inseparable from Him. It is that in God which is not God Himself, it is the yearning of the eternal One to give birth to itself. This yearning is a dumb unintelligent longing, which moves like a heaving sea in obedience to some dark and indefinite law, and is powerless to fashion anything in permanence. But in correspondence to the first stirring of the Divine existence there awakes in God Himself an inner reflective perception, by means of which—since no object is possible for it but God—God beholds Himself in His own image. In this, God is for the first time as it were realized, although as yet only within Himself. This perception combines, as understanding, with the primal yearning, which becomes thereby free creative will, and works formatively in the originally lawless nature or ground. In this wise is created the world as we know it. In every natural existence there are, therefore, two principles to be distinguished—first, the dark principle, through which this is separated from God, and exists, as it were, in the mere ground; and, secondly, the Divine principle of understanding. The first is the particular will of the creature, the second is the universal will. In irrational creatures the particular will or greed of the individual is controlled by external forces, and thus used as an instrument of the universal. But in man the two principles are consciously present together, not, however, in inseparable union, as they are in God, but with the possibility of separation. This possibility of separation is the possibility of good and evil. In Boehme's spirit, Schelling defended his idea of God as the only way of vindicating for God the consciousness which naturalism denies, and which ordinary theism emptily asserts. This theosophical transformation of Schelling's doctrine was largely due to the influence of his contemporary Baader (*q.v.*). Baader distinguishes, in a manner which may be paralleled from Boehme, between an immanent or esoteric process of self-production in God, through which He issues from His unrevealed state, and the emanent, exoteric or real process, in which God overcomes and takes up into Himself the eternal "nature" or the principle of selfhood, and appears as a Trinity of persons. The creation of the world is still further to be distinguished from these two processes as an act of freedom or will; it cannot, therefore, be speculatively constructed, but must be historically accepted. Baader, who combined his theosophy with the doctrines of Roman Catholicism, has had many followers. Among thinkers on the same lines, but more or less independent, Molitor is perhaps the most important. Swedenborg (*q.v.*) is usually reckoned among the theosophists, and some parts of his theory justify this inclusion; but his system as a whole has little in common with those speculative constructions of the Divine nature which form the essence of theosophy, as strictly understood.

Besides the books mentioned under MYSTICISM, and those referred to under individual authors, Baur's *Die christliche Gnosis in ihrer geschichtlichen Entwicklung* (1835) and Hamberger, *Stimmen aus dem Heiligthum der christlichen Mystik und Theosophie* (1857), may be mentioned. (A. S. P.-P.)

ORIENTAL THEOSOPHY

The term "theosophy" has in recent years obtained a somewhat wide currency in a restricted signification as denominating the beliefs and teachings of the Theosophical Society. This society was founded in the United States of America in the year 1875 by Madame H. P. Blavatsky (*q.v.*), in connexion with Colonel H. S. Olcott (d. 1906) and others. The main objects of the society were thus set out: (1) To establish a nucleus of the universal brotherhood of humanity; (2) to promote the study of comparative religion and philosophy; (3) to make a systematic investigation into the mystic potencies of life and matter, or what is usually termed "occultism." As regards the first object the mere fact of joining the society and becoming an "initiated fellow" was supposed to involve a certain kind of intellectual and social brotherhood, though not implying anything in the nature of an economic union. This latter aspect of the fraternity was to be satisfied by the contribution from each fellow of five dollars by way of initiation fee. The society's theory of universal brotherhood was, however, of far wider scope, being based upon a mystical conception of "the One Life"—an idea derived from and common to various forms of Eastern thought, Vedic and Buddhist. It implies the necessary interdependence of all that is—that ultimate *Oneness* which underlies and sustains all phenomenal diversity, whether inwardly or outwardly, whether individual or universal. The theosophical conception of brotherhood is thus rather transcendental than materialistic, and is not therefore to be regarded as the exact equivalent of the socialistic doctrine of the solidarity of the human race.

The second object of the society, the study of comparative religion and philosophy, soon crystallized into an exposition of a more or less definite system of dogmatic teaching. The leading thesis seems to have been that all the great religions of the world originated from the same supreme source, and that they were all to be regarded as so many divers expressions of one and the same fundamental truth, or "Wisdom Religion," in such form and dress as was best adapted to suit the times and the people for whose spiritual growth and development religious instruction was required. Now, in order to discern this underlying truth in the various and apparently conflicting world creeds, appeal was made to a "Secret Doctrine," and "Esoteric Teaching," which Madame Blavatsky proclaimed had been held for ages as a sacred possession and trust by certain mysterious adepts in occultism, or "Mahâtmâs," with whom she said she was in *psychical* as well as in direct physical communication. It is here that the theosophical movement showed its most serious shortcomings. From time to time Madame Blavatsky's numerous friends and associates were allowed to witness the manifestations of "occult phenomena," which she averred were the outcome of her connexion with these "Mahâtmâs." The fraudulent character of the "phenomena" was on several occasions exposed by numerous painstaking investigators (see *Proceedings of the Society for Psychical Research*, vols. iii. and ix., and *A Modern Priestess of Isis*, by Solovyoff). There are, moreover, numerous passages in the sacred books of the East, especially those of the Buddhists, which warn the student against the assumption that "magical" performances of any kind are to be regarded as proving the truth of the performer's teaching; and indeed it must be owned in justice to the theosophists that similar warnings are to be found scattered throughout their writings; while even Madame Blavatsky herself was wont to expatiate on the folly of accepting her "phenomena" as the mark of spiritual truth. Yet at the same time it cannot well be denied that she was in the habit of pointing to the said marvels as evidence of her Mahâtmâ's existence.

If theosophy were to be judged solely by the published revelations of this "Secret Doctrine" it would hardly be deserving of serious consideration; for, as suggested in the separate article on Madame Blavatsky, the revelations themselves appear to have been no more than a crude compilation of vague, contradictory and garbled extracts from various periodicals, books and translations. It was an article of faith with her disciples that the outward and visible Helena Petrovna Blavatsky was on certain occasions the vehicle of psychic powers of transcendent spiritual import. Although there is not much to justify such a proposition, it may perhaps be conceded that she was in many respects abnormal and that some of her work is characteristic of a process known to modern psychologists as "automatism," or in other words that it is the result of a spasmodic uprush to the surface of sub-conscious mental activities. Apart, however, from these pseudo-revelations the Theosophical Society has given rise to an extensive literature, some of which displays a high degree of argumentative and expository ability; and moreover the movement has from time to time attracted the attention and secured the co-operation of many earnest seekers, of some few of whom it can be truly said that they possessed undoubted spiritual power, insight and knowledge.

Soon after the death of Madame Blavatsky a split in the society was brought about by Mr Wm. Q. Judge (d. 1896) of New York, who claimed the leadership; and there came into existence two if not three separate theosophical societies (following Judge and later Mrs Katherine Tingley in America, Olcott and Mrs Annie Besant in America and India, with a more or less independent organization in England), each one contending that the original afflatus of the founder had descended upon it exclusively. The fortunes of the societies are, however of less importance than their leading doctrine.

It will be surmised from what has been said that any concise statement of orthodox theosophy is hardly to be expected; though from the materials available a fairly definite outline of its leading tenets can be deciphered. We will try to give a cursory review of three of the most important of these, viz.: the constitution and development of the personality or ego; the doctrine of "Karma"; and the Way or Path towards enlightenment and emancipation. Human personality, we learn, is the temporary manifestation of a complex organization consisting of "seven principles," which are united and interdependent, yet divided into certain groups, each capable of maintaining temporarily a spurious kind of personality of its own and sometimes capable of acting, so to speak, as a distinct vehicle of our conscious individual life. Each "principle" is composed of its own form of matter, determined and conditioned by its own laws of time, space and motion, and is, as it were, the repository of our various memories and volitions. These seven "principles," starting from the most gross—the physical body, or "Rûpa"—become more and more subtle and attenuated until we reach the Universal Self "Âtmâ," the centre as also the matrix of the whole, both individual and universal. Now that which binds together these elements of our nature and maintains their interrelation in their respective spheres of activity—that which determines an individual's powers, his tastes, his opportunities, advantages and drawbacks, in a word, the character—is his "Karma." Broadly speaking, it is the sum of an individual's bodily, mental and spiritual *growth*; having its roots, as it were, spread over many lives, past and future. The two sentences, "as a man soweth, so must he reap," and "as he reaps so also he must have sown," give comprehensive expression to the idea of Karmic activity.

The doctrine of Karma is with modification common to both Buddhism and Brahminism, and in their expositions theosophists have apparently drawn from both sources.

The theosophic "Path" to the final goal of emancipation or Nîrvâna, is in a great measure derived from the Buddhist literature, available to the English-speaking peoples through numerous excellent translations, more especially those of Professor T. W. Rhys Davids, and also from the many translations in all the European languages of the Bhagavad Gîtâ and Upanishads. Theosophic teachings on this subject are not, however, exclusively Oriental, for following their contention that they are the exponents of the universal and unchangeable "Wisdom Religion" of all the ages, theosophists have selected from various sources—Vedic, Buddhist, Greek and Cabalistic—certain passages for the purpose of exposition and illustration. To the uninitiated it would appear that this selection has been made, generally speaking, at random; it is at any rate lacking in the wise discrimination one would expect from the supposed source of its inspiration. Nevertheless theosophists by their investigations and expositions have undoubtedly been brought in touch with some of the most profound thought in both ancient and modern worlds; and this fact in itself has assuredly had an inspiring and ennobling influence upon their lives and work. The histories of all the great religious and philosophic movements show them as developments of an evolutionary process, arriving at their accepted dogmas through long periods of contention between numerous tendencies and cross-currents, resulting in some compromises and not a little confusion of thought. So it is in the main with theosophy. It has followed Buddhism in deprecating any reliance upon ritual. Ceremonial and sacrificial observances of all kinds are held to be useless in themselves, but operative for good or ill indirectly by their effect upon the mental attitude of those who practise them. Theosophists insist, however, that all religious observances had their origin in some mystical process, the true meaning of which has in most instances been lost. The Path is represented as the great work whereby the inner nature of the individual is consciously transformed and developed. The views of life held by the ordinary mortal as well as his aims and motives must be radically altered; and simultaneously a change must take place in his modes of speech, conduct and thought. The Path is said to be long and difficult, and with most individuals must extend over many lives. It is divided into four stages, each one representing the degree of spiritual growth and karmic development at which the "chela" or disciple has arrived. But even the entrance upon the very first stage implies something more than, and something fundamentally different from, the life of an ordinary layman, however morally excellent this life may be. Morality, important though it be as preparatory to the "higher life," does not alone lend itself to that awakening of the spiritual faculties without which progress along the Path is not possible. In good citizenship morality is practised out of regard to certain preconceived notions of the needs, the health and happiness of ourselves, our fellows and the community at large. According to theosophy, it would appear that these notions are for the most part mistaken, or at any rate they are quite insignificant in comparison with the interests with which the traveller along the Path soon finds himself absorbed. It is not that human needs are to be disregarded, but that the pabulum which he now sees that humanity really requires is of an incomparably higher order than that which is generally so considered. The physical methods and spiritual exercises recommended by theosophists are those inculcated in the systems known in Hindu philosophy as Râja Yoga in contradistinction to the Hatha Yoga system, which is most commonly to be met with in India, and in which the material aspects are given greater prominence. The Path has an active and a passive side. Fresh knowledge, new forces and faculties, have to be acquired by positive and strenuous efforts, while, on the other hand, delusions and superstitions are to be abandoned by an attitude of conscious neglect; or to use the phraseology of the Hindus, *Avidyâ*, nescience—the mental state of the unenlightened—through which the individual energies are scattered and dissipated in futile effort, is gradually replaced by *Vidyâ*, the higher wisdom which dispels the darkness of the mind, awakens our latent faculties and concentrates our efforts in the direction of that harmonious union, which ultimately results in Nîrvâna. Although the way of the disciple or "chela" is always represented as long and difficult, it is said that as he proceeds, the transcendental faculties which arise to help him enable him to pursue the right course with ever increasing confidence and security. These powers of the mind, or "siddhi," should never be sought for their own sake, or be used for selfish purposes. The attempt to develop and use them without regard to the higher purpose is spoken of as practising the arts of "black magic," the exercise of which invariably leads to disaster. It is proclaimed that were the "chela" to attempt to make an improper use of his powers—that is to say, were he to yield to the promptings of selfishness, lust or antagonism—such a lapse would at once set in action counteracting forces, which not only retard his upward growth, but which would, were such evil courses persisted in, lead ultimately to the obliteration of all his newly acquired psychic possessions.

The Path may also be described in terms of the "seven principles." It may be said to be a process of *unification*, whereby the centres of volition, consciousness and active memory are systematically shifted upwards from the lower to the higher "principles" until they have become firmly established in the "Buddhi," or "sixth principle." As this last stage is approached the "chela" becomes less and less dependent on the guidance of traditions and scriptures. The truth becomes revealed to him by the opening of his inner vision, and he learns to see Dharma, the Eternal Law, as it were, face to face. Thus theosophists may be said to accept in their own sense the saying: "He who does the Will shall know the doctrine."

Along the Path are ranged ten great obstacles, or fetters, the Buddhist Sanyojanas, which have to be successively overcome before the final goal is reached. As these sanyojanas give a very good idea of what has been termed the negative aspect of the Path, we may enumerate them as follows:—

1. The delusion of personality—the belief in a permanent and unchangeable egoentity.
2. Doubt as to the use of the higher efforts, or as to the possibility of solving the great mysteries of life.
3. The reliance upon ritual—seeking salvation through outward acts.
4. Lust.
5. Ill-will, or antagonism.
6. Love of this life and its possessions—"The care of the world and the deceitfulness of riches."
7. The egoistic longing for a future life.
8. Pride.
9. Self-righteousness.
10. Nescience.

A few words should be added as to the theosophic hell, or "Avichi." This is described as a long drawn-out dream of bitter memories—a vivid consciousness of failure without volition, or the power of initiative—a dream of lost opportunities and futile regrets, of ambitions thwarted and hopes denied, of neglected duties, abused powers and impotent hate; a dream ending ultimately in the oblivion of utter annihilation.

There is no doubt much of valuable suggestion to be found in the philosophic system, or rather the conglomerate of systems, which pass to-day under the name of theosophy; and probably much has been done by means of its propaganda to popularize Eastern thought in the West, and in the East to reawaken a truer appreciation of its own philosophic treasures; but however that may be, the serious student would be well advised to seek his information and his inspiration from the fountain-heads of the theosophists' doctrines, which are all easily accessible in translations; and to avoid the confusions and errors of writers who in most cases have but a superficial if any knowledge of the original languages and systems from which their doctrine has been arbitrarily culled. (St G. L. F.-P.)

THÉOT, CATHERINE (d. 1794), French visionary, was born at Barenton (Manche). From her youth a victim of hallucinations, a long course of religious asceticism in the convent of the Miramiones in Paris unhinged her mind, and she was placed under restraint. Liberated in 1782, her early delusions concerning a Messiah became accentuated; that she was destined to be the mother of the new Messiah, she was now assured; she pictured to her followers the fantastic features of the coming Paradise on earth; and was hailed as the "Mother of God." From the idea of the advent of a Messiah to its realization was but a step; in Robespierre the Théotists saw the redeemer of mankind; and preparations for his initiation were put in train. The enemies of Robespierre, resenting his theocratic aims, seized upon his relations with the Théotists as an engine of revenge; Catherine, with Gerle (*q.v.*) and others, was arrested and imprisoned, and a letter to Robespierre discovered in her house. In the Convention M. G. A. Vadier trumped up the conspiracy of Théot, asserting that Catherine was a tool of Pitt, that the mummeries of the Théotists were but a cloak for clerical and reactionary intrigue, and hinting that Robespierre favoured their designs. The case was adjourned to the Revolutionary Tribunal, and figured in the proceedings of the 9th Thermidor. The accused were ultimately acquitted, Catherine herself having died in prison on the 1st of September 1794.

THERA, the southernmost island of the Sporades, now called Santorin (*q.v.*). It was known as Thera until after the Fourth Crusade, when it became part of the duchy of the Archipelago.

THERALITE (Gk. θηρᾶν, to pursue), in petrology, a group of plutonic holocrystalline rocks consisting of nepheline, basic plagioclase, augite and olivine, and so called because it is of rare occurrence, and its discovery was looked forward to with interest as completing the series of basic rocks containing nepheline as an essential constituent. The felspars are mostly of basic character and are often zonal; the nepheline is of later crystallization, rarely idiomorphic and often decomposed. Pyroxene in these rocks may be of green colour or purplish-brown and rich in titanium; olivine is usually abundant. Among the accessories may be mentioned apatite and iron oxides, biotite and dark brown hornblende, the latter often surrounding the purple augite. The rocks have rarely ophitic structure, but their minerals tend to have good crystalline form, except in the case of nepheline and orthoclase (if that be present). By decomposition the nepheline yields zeolites such as natrolite and analcite. The theralites are rarely cross-grained and have much resemblance to dolerites in hand specimens. Among localities for these rocks are Duppau in central Bohemia, Pridazzo (W. Alps), Umptek (on the White Sea), Madagascar and the Crazy Mountains in Montana. A variety of theralite occurs also at Montreal in Canada, and rocks from Crawford John in Lanarkshire and from Paisley in Renfrewshire have recently been ascribed to this group.

Very close to the theralites is a series of rock types known as the teschenites (from Teschen in Moravia). Instead of nepheline these rocks usually contain analcite, and from their microscopic characters it is by no means likely that the analcite is secondary after nepheline in this case; it appears, in fact, to be either primary or of pneumatolytic origin. Nepheline, however, has been found in teschenites from Portugal and from Moravia, so that the distinction between the two series practically vanishes. In central Scotland, around Edinburgh and Glasgow, teschenites are abundant, forming thick sills intrusive into the Carboniferous rocks, and some are also known from Leicestershire (Whitwick) and from Arran. These teschenites are sometimes ophitic and present transitions to olivine-diabases on the one hand and to picrites on the other. They are the deep-seated representatives of the basaltic lavas which were emitted in great numbers in the early part of the Carboniferous period. Other localities for teschenite are the Caucasus and the coast of California (Cuyama Valley, &c.).

The essexites are an allied series containing a larger amount of alkali felspar. Nepheline also occurs by no means uncommonly; the augite is sometimes green, but in other specimens is of a rich purple colour with well-marked zonal structure. Olivine is by no means uncommon, and brown hornblende and biotite occur rather frequently. The type rock is from Essex (Massachusetts) and other examples have been described from Rongstock on the Elbe, from Mount Royal (Montreal), from S. Norway, near Christiania, and from St Vincent in the Cape Verde Islands. A few essexites have been found in Britain, accompanying the Carboniferous teschenites near Edinburgh and in the Campsie Hills of Stirlingshire. As they contain both orthoclase and plagioclase felspar they have a certain affinity to the olivine-monzonites and kentallenites.

The shonkinites are dark grey rocks consisting of olivine, green augite, dark brown biotite, nepheline and orthoclase, which are found at Shonkin Sag in the Highwood Mountains of Montana. They are basic variations of sodalite-syenite and have some resemblance to theralites, especially in the association of nepheline with large amounts of augite and olivine. They are of exceedingly rare occurrence. (J. S. F.)

THERAMENES (d. 403 B.C.), Athenian statesman, was the adopted son of Hagnon, a prominent conservative who in 430 impeached Pericles, and after the Sicilian expedition became one of the ten *probuli* (*πρόβουλοι*, commissioners) appointed to devise economies in the administration. As a pupil of the sophist Prodicus he acquired facility in public speaking. Under his father's patronage he joined in the conservative reaction which came to a head in 411, when hopes of a Persian alliance or peace with Sparta strengthened the existing dissatisfaction with the democratic rule. Theramenes specially studied the constitutional side of this movement and formulated a new party-cry, "the constitution of our fathers." It was no doubt largely due to his advocacy that the *probuli*, strengthened by further members, were commissioned to draft new measures on behalf of the public safety and to examine Cleisthenes' "ancestral code." In their report the following measures were recommended: (i.) annulment of the act against promulgating illegal measures; (ii.) abolition of pay, save for the troops in the field and the archons; (iii.) restriction of the franchise to 5000 able to serve "with person and purse"; (iv.) the appointment of a special board to choose the 5000. When these proposals were passed (apparently in a packed assembly outside the walls), a Constituent Assembly of 100 was elected, nominally by the 5000, who as yet were a mere phantom body, in point of fact by the leading conspirators. The new constitution provided for a boulē whose members were to be recruited by lot from all citizens above thirty; the functions of this body to be exercised by four sections succeeding one another by yearly rotation and serving without pay; all high officials to be chosen by it out of its own members. This scheme embodied the chief reforms desired by Theramenes, and marks the triumph of his policy. But before it could be carried into effect it was superseded by a "provisional constitution," which gave unlimited power to a boulē of 400 (chosen by a roundabout system which favoured intrigue) and its nominees, the ten "absolute" generals. This extreme reaction displeased Theramenes, who in return began to agitate for the calling of the 5000 into real existence. Furthermore he warned Athens against the treason of the extreme oligarchs, and induced the troops to raze a mole erected to facilitate a Spartan descent on Peiraeus.

After the disaster of Eretria (see PELOPONNESIAN WAR), which caused the fall of the extremists and the institution of a government of "5000" (*i.e.* all citizens who could afford a suit of armour), Theramenes stood in high esteem. After assisting in the prosecution of his former colleagues he received the command of a squadron with which he helped to win the great victory at Cyzicus (410) and to recover the Bosporus. After the triumph of the radical democrats which followed upon these successes he lost his high command. At Arginusae (406) he fought as a simple ship's captain, but after the battle was commissioned by the generals to rescue some drowning crews, an order which, with his ill-trained and exhausted troops, in a heavy storm, he was unable to carry out. For this failure the generals were severely criticized at Athens; an inquiry by the boulē led to their arrest, and before the ecclesia they aggravated their case by pleading (i.) that the storm made a rescue impossible, (ii.) that Theramenes was to blame. Theramenes in reply brought out the implied contradiction in these statements, and in consequence the assembly condemned the accused to death and subsequently returned Theramenes general.

Late in 405 Theramenes went as plenipotentiary to Lysander (*q.v.*) to obtain peace terms; after long negotiations he proceeded to Sparta and arranged a settlement which the Athenians ratified (April 404). In spite of this peace the disorder in Athens did not abate. The restored fugitives selected five "ephors," including Critias, to organize a revolution, while the radicals opposed that return to the "ancestral constitution" for which Theramenes had stipulated. Hereupon Lysander returned to Athens and had a Constituent Committee elected, of whom ten members were nominees of each section. In this body Theramenes at first assumed the chief part, and the new measures rescinding the laws against the Areopagus and suppressing sycophancy were well received. But, exactly as in 411, a more violent party under Critias, forgetting its real duties, appointed an autocratic boulē of its own creatures, and proceeded by judicial murders and confiscations to earn for the new government the name of "the Thirty Tyrants." Theramenes protested, and managed to get a citizen-body of 3000 admitted to a share of the government. Critias, however, fearing a renewal of the collapse of 411, disarmed the people and decided to remove Theramenes before he could create a new democratic party. The latter successfully repelled Critias' denunciation of treason, but was led away by violence and forced to take poison. His well-known gibe, "Here's to the noble Critias," attests his strength of mind at the hour of death.[1]

Theramenes demonstrably had a definite policy throughout his career. His ideal was a return to a 6th century constitution, which his contemporaries could equally regard as a moderate oligarchy or a restricted democracy. The main features of his programme were: (1) property qualification for franchise; (ii.) abolition of pay; (iii.) transference of some judicial powers from the popular courts to a restored Areopagus. At times he seemed likely to succeed, but amid the violent oscillations of party he could not definitely join any one faction, and so earned the nickname *Κόθορνος* (a stage-boot fitting either foot). Aristotle, however, discerned Theramenes' real policy, and, like Cicero and Caesar, in later years ranked him among the greatest Athenian statesmen.

SOURCES.—The *Constitution of Athens* with its numerous documents affords much valuable knowledge, but does not give the inner history of 411. Thucydides viii. supplies this, but his

[1] The attempted rescue by Isocrates (Pseudo-Plutarch, *Vitae X. Oratorum*) is improbable; but Theramenes may have taught Isocrates in oratory.

knowledge of the constitutional side of the revolution and of Theramenes' activity is somewhat fragmentary. Xenophon (*Hellenica*, i., ii.) was an eye-witness in 406–403, but is clearly inaccurate in his details and prejudiced throughout. Lysias (*c. Eratosth.* and *c. Agorat.*) gives an avowedly hostile account of Theramenes. Diodorus xiii., xiv., goes too far in making Theramenes a pure democrat. See also Plutarch, *Cicero*, chap. 59; Cicero, *de Oratore*, iii. 16, 59; Wilamowitz-Möellendorff, *Aristoteles und Athen* (Berlin and Leipzig, 1893), ii. p. 113 sqq.; E. Meyer, *Forschungen zur alten Geschichte* (Halle, 1899), ii. pp. 406 sqq.; B. Perrin in *American Historical Review*, ix. (1904), pp. 649–69. (M. O. B. C.)

THERAPEUTAE (Gr. θεραπευταί, literally "attendants" or "physicians," hence "worshippers of God"), a monastic order among the Jews of Egypt, similar to the Essenes. Our sole authority for their existence is Philo in his treatise *De Vita Contemplativa*. He takes them as the type of the contemplative, in contrast with the Essenes, who represented rather the practical life. While the Essenes were confined to Palestine or its near neighbourhood, the Therapeutae, we are told, existed in many parts of the world, but especially in Egypt. Their headquarters there were on Lake Mareotis, which at that time debouched into the sea. This establishment near Alexandria was, as it were, the Grande Chartreuse of their order. Philo himself was uncertain as to the meaning of the name, whether it was given to them because they were "physicians" of souls or because they were "servants" of the One God. Their mode of life he in one place (ii. 473, line 14) calls θεραπεία, and his use of words generally accords better with the latter meaning. That the origin of the name of these ascetics was unknown in Philo's time goes to prove their antiquity.

A man on joining the order died to the world, and so voluntarily resigned his property to his heirs. How the order itself was supported does not appear. So far as we are informed, prayer and study were the sole occupations of the Therapeutae. The community at Alexandria lived in mean and scattered houses, near enough to afford protection, without depriving the members of the solitude which they prized. Each of these houses contained a chamber called σεμνεῖον or μοναστήριον (cf. Matt. vi. 6), which was devoted to prayer and study, and into which the inmate brought nothing but the Law and the Prophets, together with the Psalms and other works which tended to the promotion of piety. At sunrise the Therapeutae prayed and again at sunset. The whole interval was devoted to a study of the internal sense of the Scriptures. In addition to the Old Testament the Therapeutae had books by the founders of their sect on the allegorical method of interpreting Scripture. They also contributed to sacred literature themselves in the composition of new psalms. Attendance to the ordinary needs of nature was entirely relegated to the hours of darkness. Some of these recluses only ate every second day, while others succeeded in confining the necessity to a single week-day. But the Sabbath was a feast on which, after attending to their souls, they indulged their bodies, like yoke animals let out to graze. But their indulgence even then is not mentioned to have gone beyond the coarse bread, flavoured with salt and sometimes hyssop, while their drink was water from the spring. Thus during the six days of the week the Therapeutae "philosophized," each in his own cell, but on the Sabbath they met in a common assembly, where women also had places screened off from the men, and listened to a discourse from one who was the eldest and most skilled in their doctrines.

In contrast with the drunken revels of the Greeks, Philo describes the sober enjoyment by the Therapeutae of the feast of Pentecost, or rather of the eve of that festival. They assembled together with glad faces and in white garments, and the proceedings were begun with prayers, in which they stood and stretched their eyes and hands to heaven. Then they took their seats in the order of their admission, the men on the right and the women on the left. Slavery being against their principles, the younger members of the society waited on the elder. No flesh was served at table, and for drink only water either hot or cold. But first came "the feast of reason and the flow of soul." All listened devoutly to a discourse delivered with an emphatic slowness and penetrating beneath the letter of the Law to the spiritual truth that lay hidden within. When the president's address had been duly applauded, there followed the singing of hymns ancient and modern. Then came the meal of the simple kind already described. And after this a *pervigilium*, celebrated with antiphonal and joint singing on the part of men and women and with choral dancing in imitation of Moses and Miriam at the Red Sea. At sunrise, turning to the east, they prayed that the light of truth might illumine their minds, and then returned to their studies.

Such is the account of the Therapeutae given by Philo. It seems to have formed part of the Apology for the Jews (Eus *Pr. Ev.* viii. 10, § 12)—hence its highly rhetorical character—from which Eusebius gives the extract about the Essenes; while this in its turn may have constituted the fourth book of a large work entitled ("sarcastically," says Eusebius, *H.E.* ii. 18) περὶ Ἀρετῶν, of which the *Legatio ad Gaium* formed the first. The *De Vita Contemplativa* thus owes its place next to the *Quod Omnis Probus Liber*, a place which it already occupied in the copy of Philo's works possessed by Eusebius (*H.E.* ii. 18), merely to the mention of the Essenes at the beginning of it.

To the modern reader the importance of the Therapeutae, as of the Essenes, lies in the evidence they afford of the existence of the monastic system long before the Christian era. We have no clue to the origin of the Therapeutae, but it is plain that they were already ancient when Philo described them. Eusebius was so much struck by the likeness of the Therapeutae to the Christian monks of his own day as to claim that they were Christians converted by the preaching of St Mark. He goes so far as to say that "the writings of ancient men, who were the founders of the sect" referred to by Philo, may very well have been the Gospels and Epistles (which were not yet written). This is a strong instance of how the wish may be father to the thought even in a fairly critical mind. Eusebius having gone wrong on this point, others of the Fathers followed suit, so that Philo is reckoned by Jerome among the ecclesiastical writers of the Christians.

Nothing is more likely than that Christianity gained adherents among the Therapeutae, and that their institutions were adapted to the new religion, just as they seem to have been borrowed by the Jews from the Egyptians. Strabo (xi. 29, p. 806) tells us how he saw at Heliopolis large buildings belonging to the priests, which had once been tenanted by men skilled in philosophy and astronomy, who had been consulted by Plato and Eudoxus, but that the σύστημα and ἄσκησις (the very words used by Philo in speaking of the Therapeutae) had then fallen into decay. The system, however, was not even then extinct, for it was described by Chaeremon the Stoic, a contemporary of Strabo's. Chaeremon's account has been preserved by Porphyry (*De Abstinentia*, iv. 6), and has curious resemblances to Philo's description of the Therapeutae, even down to such details as their posture and gait and the eating of hyssop with their bread.

After 1879 a theory became current in Germany (first stated in P. E. Lucius, *Die Therapeuten und ihre Stellung*), and accepted in England, to the effect that the *De Vita Contemplativa* is not a work of Philo's at all, but a forgery put forward about the end of the 3rd century and intended to procure the authority of Philo's name for the then rising monasticism of the Church. But this theory was signally refuted by F. C. Conybeare in his *Philo about the Contemplative Life* (Oxford, 1895).

See also works quoted by Conybeare (pp. 391–399); Bousset, *Religion des Judenthums im neutestamentlichen Zeitalter* (1903); A. Harnack, *s.v.* "Therapeuten" in Herzog-Hauck, *Realencyk.*, xix. 677 (1907). (St G. S.)

THERAPEUTICS (Gr. θεραπευτική, *sc.* τέχνη, from θεραπεύειν, to serve), the name given to that branch of medicine which deals specifically with the means employed to cure disease if possible, or to control and lessen its evil results when a cure is impossible.

The cure which is sought for may either be *symptomatic* or *radical*. Various morbid conditions of the body generally may give rise to different symptoms. Thus a gouty condition may manifest itself in one man as eczema of the skin, giving rise to redness and intense itching; in another as neuralgia, causing most severe pain; in a third as bronchitis, producing a distressing cough; in a fourth as dyspepsia, giving rise to flatulence and intestinal disturbance; and in a fifth as inflammation of the great toe, accompanied by redness, swelling and pain. The therapeutic measures employed in these different cases may be directed towards alleviating the symptoms, such as itching, pain, cough and swelling, in which case the treatment will be merely *symptomatic*; or they may be directed towards removing the root of the disease, viz. the gouty condition underlying them all, and thus effecting a *radical* cure. It very frequently happens that we do not know what the underlying condition is, and we are forced simply to relieve as best we can the most prominent and most distressing symptoms. In symptomatic treatment we are frequently obliged to use remedies simply because we know they have done good before in similar cases, and we expect them to do so again without having the least idea of how they act. Thus in acute gout the most common and most trusted remedy for removing the pain is colchicum, but at present we do not know what action it has upon the system, or why it gives so much ease in the pain of gout while it has comparatively little effect upon pain due to other causes. This plan of treatment is termed *empirical*. It is a useful method, and is often very satisfactory, but it has the disadvantage that it admits of but little progress, and when a trusted empirical remedy fails we do not know precisely in what direction to look for a substitute. In contradistinction to empirical we have *rational* therapeutics, by which we mean the application of a remedy, whose mode of action we know more or less perfectly, in diseased conditions, the nature of which we also understand more or less fully. As an example may be taken the use of nitrite of amyl in angina pectoris. It has been found that in many cases of this disease the pressure of blood within the arteries becomes increased, probably from spasmodic contraction of the arteries themselves. Nitrite of amyl has the power of dilating the arteries; it has consequently been employed with much success in lowering the blood pressure and removing the pain in angina pectoris. But such rational knowledge as this not only enables us to remove pain at the time, but helps us to prevent its recurrence. For on the one hand knowledge of the fact that nitrite of amyl lessens blood pressure has led to the successful employment of other nitrites and bodies having a similar action, and on the other the knowledge that increased blood pressure tends to cause anginal pain leads to the prohibition of any strain, any food, any exposure to cold, and also of any medicines which would unduly raise the blood pressure. Here we notice one of the greatest advantages of rational over empirical therapeutics. In cases of angina, while the resistance opposed to the action of the heart by spasm in the vessels may be great, the heart itself may be feeble, and it may therefore be necessary to give some remedy which will increase the power of the heart. But if such a remedy were given alone it might, and probably would, act on the arteries as well as the heart, and by causing the contraction of the vessels do more harm than good. But if we know what remedies will increase the power of the heart and what will lessen resistance in the vessels, we may combine them and thus obtain the objects we desired, viz. removal of the pain, better action of the heart, and more perfect circulation.

The testing of ideas by observation and experiment which was begun in anatomy by Vesalius. and by Harvey in physiology, was applied by Morgagni to alterations in the organs produced by disease, by Bichat to the tissues, and by Virchow to the cell. The study of disease in the living body may be said to have been begun by John Hunter, developed by Magendie, Claude Bernard, Brown-Séquard and others. Of late years enormous impulse has been given to our knowledge of the causation of disease by microbes, through the works of Gaspard, who injected putrid matter into the veins of a living animal; by Villemin, who discovered that tuberculosis is infective; by Davaine; and especially by Pasteur, Koch and others too numerous to mention, who have worked, and are still working, at the microbic causation of disease with marvellous success.

The natural end of life is that all the organs should become old and gradually decay at the same time, so that at the last the individual should become less and less active, weaker and weaker, and finally die without any definite disease, without pain and without struggle. But this is exceptional, and generally one part gives way before another, either on account of one part being naturally weaker or of one part having been overtaxed or more severely attacked by some injurious external influence, or by some undue preponderance of another part of the body itself. For health consists in a due proportion between the action of all the different parts of the body, and if one part be unnaturally strong it may lead to injury or death. Thus a very strong heart, although it may be useful to its possessor for many years, driving the blood rapidly through the vessels, and supplying all his tissues with such abundant nutriment as to enable him to endure great exertion, mental or bodily, may in the end cause death by bursting a vessel in the brain, which might have resisted the pressure of a feebler circulation for years longer. On the other hand, a heart that is too feeble may cause its owner's death by its inability to carry on the circulation against increased resistance. This may occur suddenly, as when the resistance is increased in the arterial system by a sudden exertion or strain, and more slowly when the resistance is increased in the pulmonary circulation by inflammation of the respiratory passages. The thyroid gland, which is situated in front of the neck, yields a secretion which passes into the blood and there tends to maintain a state of moderate dilatation in the blood-vessels and of oxidization in the tissues, so that the circulation remains good and the body-heat and muscular activity remain well maintained. When this gland becomes enlarged, and its secretion consequently increases, the vessels dilate, the heart beats more rapidly, the skin becomes too hot, the nervous system becomes irritable, and tremors occur in the limbs. On the other hand, when it becomes atrophied the circulation becomes feeble, the face heavy and dull, the patient suffers from cold, the features grow lumpish, mental processes become sluggish, and bodily vigour diminishes.

Disease by feebleness or excessive action of one part of the body.

Disease of the whole body may thus be produced by over-action or under-action of some part of it, but such causes of disease are slight as compared with the effect of external noxious influences, and more especially the effect of microbes. These enter the body through various channels, and once they have effected a lodgment they grow, multiply and give rise to various poisons which attack and injure or destroy different tissues or organs in the body. Various safeguards are provided by nature to prevent their entrance. On the skin we have a thick epidermis through which microbes cannot pass, although if an entrance is obtained for them by a prick or cut they may readily grow in the tissues below and spread from them throughout the whole body. They pass more readily through mucous membranes, but almost every one of these is provided not only with a coating of mucus, which obstructs their passage, but with some reflex mechanism which tends to remove them. Thus irritation of the eye causes winking and secretion of tears, by which the irritant is removed; irritation of the nose causes sneezing; of the air-passages, coughing; of the stomach, vomiting; and of the intestines, diarrhoea. Even when they have passed through an abrasion in the skin or through the mucous membranes and enter the blood they are met, in some instances, by a toxic action of the blood itself upon them; and in others they are attacked by the white corpuscles, which destroy them, eat them up, and digest them, the process being known as *phagocytosis*. The greater the number of leucocytes that can reach the spot where the invading microbes enter the more quickly can the microbes be destroyed and general infection prevented. The microbes appear in many cases to attract the leucocytes (positive chemiotaxis), but when very virulent they usually repel the leucocytes (negative chemiotaxis)

Microbes.

and excrete toxins which kill the leucocytes. The irritation caused by the microbes generally is followed by dilatation of the vessels of that part and thus more leucocytes are brought up to the fight. This dilatation may be increased by local warmth, and poultices or fomentations are commonly applied to inflamed parts; recently suction apparatus has been used for the same purpose or ligature so as to cause venous stasis (Bier's treatment). Blisters also cause local dilatation of vessels, but are usually applied to the skin for inflammation in deep-seated parts, such as the lungs, though they also relieve pain in the joints in acute rheumatism. Bier increases the blood in a part by compressing the veins and thus producing passive instead of active congestion. The toxins produced by microbes, if too weak to destroy the leucocytes, induce them to secrete anti-toxins, which not only act as antidotes to the toxins and are injurious to the microbes, but also increase the phagocytic power of the leucocytes (opsonius of Wright). By inoculation with increasing doses of these the resistance of the organism is greatly increased and the invading microbes destroyed. The vaccine is usually made by sterilizing a virulent culture and the proper dose is ascertained by noting the extent to which the power of the leucocytes to envelop and digest the microbes is increased.

Moreover, the products of microbic secretion tend to produce *fever*. The high temperature characteristic of this condition is no doubt injurious to the body itself, but it is frequently more so to the microbe which has invaded the organism; and thus fever, instead of now being regarded as a morbid condition to be suppressed by every means in our power, is considered to be a reaction of the organism tending to protect it by destroying the infection. But it must be kept within limits, lest it should of itself cause death, and here again we see the difference between empirical and rational medicine. Fever is not to be looked upon as an unmitigated evil, to be removed if possible, but rather as a defensive mechanism by which the organism may prevent invasion from noxicus microbes. Nevertheless, as in a campaign the general's plan may be spoiled by too hasty or too eager action on the part of some of his troops, so the defensive arrangement carried to excess may prove injurious or fatal to the organism. Thus too great a rise of temperature in fever may kill the patient; and the aim of therapeutics is to restrain the temperature within proper limits, neither allowing it to rise too high nor to fall too low. The old plan of lowering it by means of cold baths was known to Musa, the physician of Augustus, and by it he saved the emperor's life; but the same treatment killed the emperor's nephew. The introduction of the clinical thermometer, which allows us to ascertain exactly the amount to which the temperature rises in fever or to which it is reduced by antipyretic measures, is to the physician like the compass to the sailor, and allows him to steer safely between two extremes.

After the struggle between the organism and the microbes is over, even when it has ended victoriously for the former, injuries are left behind which require repair. Every one has noticed after prolonged fever how thin and weak the patient is, and both the muscular and nervous power throughout the whole body are sadly in want of repair. Where there has been local mischief due to inflammation the dead leucocytes must be removed, and this is done either by their being converted into pus in one mass, and making their way through the tissues to the nearest surface, whether of skin or mucous membrane, from which it can be discharged, or they may undergo a process of fatty degeneration and absorption, leaving behind in some cases cheesy matter, in others hard connective tissue.

Poisons formed by microbes are partly eliminated by the kidneys, partly by the mucous membrane of the stomach and intestines, and possibly also by the skin. In old days free elimination by these channels was looked upon as a sign of returning health, and was termed a "critical" diuresis, diarrhoea or sweating, according to the channel through which the eliminative act had occurred.

By therapeutic measures we strive to limit as far as possible the entry of injurious microbes into the organism, to expel or destroy them and their harmful products, and to maintain the strength of the organism itself. One of the influences which is most injurious to the body, and favours most the invasion of microbes, is *chill*. So much is this the case that some diseases which are now known to be due to infection were formerly attributed entirely to the effect of cold. Thus pneumonia is now known to be due to the diplococcus pneumoniae, and yet its invasion occurs so frequently after a chill that it is almost impossible not to look upon chill and pneumonia as cause and effect. The reason of this appears to be that the diplococcus is frequently present in the mouth or air-passages without giving rise to any symptoms; but when the patient is exposed to chill, and the tissues of the respiratory passages are thereby weakened, the diplococcus grows, multiplies and gives rise to inflammation of the lungs. Even what are known as common colds are probably due chiefly to microbic infection aided by a chill, just as in the case of pneumonia. Therapeutic measures which are commonly adopted in the treatment of a cold have for their object to destroy the microbes before they penetrate fairly into the organism, and to restore the balance of the circulation and increase the strength of the invaded parts. Thus carbolic acid or carbolized ammonia are sniffed into the nose to destroy the microbes there, or the nose is washed out by an antiseptic solution as a nasal douche; bismuth or morphine are insufflated, or zinc ointment is applied, to cover the mucous membrane, and protect it from further irritation; and various antiseptic gargles, paints and powders applied to the pharynx in order to prevent the microbic inflammation from extending to the pharynx and down the trachea and bronchi, for many a severe bronchitis begins first by sneezing and nasal irritation. Sometimes the patient is put to bed and the circulation is encouraged, especially on the surface of the body, by the use of hot spirits and water, or opium and ipecacuanha, while the outside of the nose is protected to a certain extent from loss of heat, and consequent irritation, by smearing it with a tallow candle or rubbing some ointment over the skin. At the same time, if the throat has begun to show signs of being involved, a hot poultice or wet pack is applied to the neck.

Both inflammation and fever are protective processes calculated to defend the organism against the attacks of microbes. But protective processes misdirected or carried to excess may become injurious or even dangerous to the organism. As an instance of misdirection, we may take the irritation which remains in the eye after a particle of dust has been removed, or the itching of the skin which occurs in eczema. The irritation of the conjunctiva caused by dust leads to winking of the eyelids, lachrymation and rubbing, which tend to remove it; but after the dust has been removed violent rubbing tends rather to keep up the irritation; and sometimes, if the particle of dust remains under the eyelid and is sharp and angular, the process of rubbing may cause it to injure the conjunctiva much more than if it were left alone. In the same way itching is often caused by the presence of insects or other irritants upon the skin, and it tends reflexly to cause rubbing, which is useful by removing the irritant. But when the irritation is situated in the skin itself, as in eczema, the scratching tends to increase inflammation, and makes the irritation worse. In the same way, the reflex act of coughing is useful in removing either foreign bodies or excessive secretion from the air passages; but when the mucous membrane of the respiratory tract is irritated and inflamed, it produces a feeling of tickling and a desire to cough sometimes very violently; yet the coughing simply tends to exhaust the patient, because there is really little or nothing to bring up. The same is the case in inflammation of the lung substance itself. As an example of excessive action we may take sneezing, which is calculated to remove irritants from the nose, but when too powerful may cause the patient to burst a blood-vessel. In phthisis also, although there may be some expectoration to bring up, yet a good deal of the irritation is in the lung substance, and the efforts of coughing are far greater and more continuous than are required for the removal of expectoration, and they simply exhaust the patient. In inflammation of the stomach also such continuous vomiting occasionally occurs that the patient's life is in danger by his inability to retain food; and similar danger also occurs from inflammation of the intestines and consequent diarrhoea.

We will next take the various parts of the body, and consider more in detail the therapeutic measures most commonly employed in the treatment of their diseases. The defensive powers of the body against microbes, when actually on or in it, may be classed as means (1) of passive defence, (2) of active defence, and (3) of repair. Besides these, however, we must consider the protection of the whole body from injury caused by (*a*) inaction, or (*b*) overaction, or (*c*) weakness of any one of its parts. The means of passive and active defence are sometimes so closely associated that it is difficult to distinguish between them. Thus if a little diphtheritic sputum were coughed into a person's eye, or some blood containing anthrax bacilli were to touch a raw spot upon the hand, the removal of microbes in either case by washing with simple water might be regarded as a means of passive defence, whilst washing them away with an antiseptic lotion might be regarded as active defence, because the antiseptic would tend not only to remove but to destroy the microbes. In the same way, washing the skin with spirit would tend to harden the epidermis and thus prevent the entrance of microbes; and the application of an ointment to an abrasion would have a similar action. But by the addition of some antiseptic to the ointment its defensive action would be converted from passive to active, and its power to prevent infection would become greater; and if inflammation had already set up in the skin, the addition of opium, belladonna, or cocaine would lessen local pain; and an astringent, either metallic or organic, would restrain inflammation and accelerate repair. The thickening of the epidermis in the hands and feet, which occurs from constant use, is nature's provision for meeting the extra wear to which these parts are subjected by much use; but pressure is apt to cause the defensive process to be carried too far, and to lead to corns, which give rise to much pain and annoyance. To remove these salicylic acid dissolved in flexible collodion is now generally employed. When this is painted upon the part the corn usually peels off in a day or two, and the patient is cured.

Defensive measures.

But the object of therapeutics is not merely to cure. It is, in the words of the old formula, *Curare, cito, tuto, et jucunde*, to cure quickly, safely, and pleasantly. There are therefore in most prescriptions (1) a basis or chief ingredient intended to cure (*curare*), (2) an adjuvant to assist its action and make it cure quickly (*cito*), (3) a corrective to prevent or lessen any undesirable effect (*tuto*), and (4) a vehicle or excipient to make it suitable for administration and pleasant to the patient (*jucunde*). In the remedy just mentioned the salicylic acid forms the basis; but sometimes chloride of zinc or lactic acid is added to it to make it act more quickly, and these are the adjuvants. Extract of belladonna is added to lessen the pain which might occur during the removal of the corn, and this acts as a corrective, while the flexible collodion forms a means of applying it conveniently, and constitutes the vehicle.

Principles of cure.

The surface of the skin may be invaded by parasitic organisms and may exhibit spots, which are removed by something which will destroy the parasite, such as ointments containing mercurial salts. In psoriasis the epidermis separates in flakes at various spots which have not been subjected to pressure, and to cure it ointment containing tar or other products of the dry distillation of wood is employed. When the true skin is inflamed various appearances may arise, according to the intensity and extent of the inflammation, and the eruption may be papular, vesicular, pustular, tubercular, bulbous or ulcerative. To lessen irritation the skin is protected by dusting powders, such as oxide of zinc, starch, fuller's earth, &c., or by ointments. Irritation is lessened by lotions containing substances that will diminish irritability of the nerve-endings and skin, such as carbolic acid, hydrocyanic acid, morphine or opium, cocaine, belladonna or atropine. Where the surface is ulcerated it may be protected from external violence and placed under favourable conditions for healing by covering it with lint moistened with water and with oil-silk over it to prevent evaporation. If the granulations tend to become too abundant, some astringent, such as sulphate of copper or sulphate of zinc, is added to the water. On the other hand, when the ulceration is old and the circulation through it poor, the aim of the therapeutist is to reawaken the normal reparative process, to bring about increased circulation and increased tissue change, and thereby insure healing. For this reason a blister is placed upon the callous ulcer, which heals with the fresh inflammation thus excited.

Inflammation.

The treatment of inflammation of mucous membrane is based upon the same principles as inflammation of the skin, and there too we usually associate means (1) for removing microbes, (2) for destroying them, (3) for lessening the irritation they produce, and (4) for repairing any mischief they have done. Thus in the eye and ear, lotions containing an antiseptic, a sedative and an astringent are very generally used. For inflammation of the mouth a similar combination is used as a mouth wash, in the throat as a gargle, and in the nose as a wash and sometimes as an ointment or spray, the ointment possessing the advantage of protecting the delicate nasal mucous membrane from irritation by stopping the entrance of irritant dust into the nasal cavities. In the stomach we aid the vomiting by which microbes or the products of decomposition of food are usually eliminated by giving to the patient repeated draughts of hot water so as to wash the stomach clean. Frequently this is sufficient; but if the stomach refuses to eject its objectionable contents, we may either give an emetic or wash it out by means of a stomach-pump or siphon. Similar procedures are used for the intestine, and one of the best methods of treating the diarrhoea consequent upon the presence of irritating substances in the intestinal canal is to give a dose of castor-oil together with a few drops of laudanum. By means of the castor-oil the irritating substances are removed, and the laudanum which is mixed with the purgative soothes the intestine. Even in cases of very acute intestinal diseases similar treatment is now pursued, and instead of treating dysentery simply by sedatives or astringents, an eliminative treatment by means of sulphate of magnesia is largely employed. After the irritant has been removed either from the stomach or intestine, a feeling of irritation of the mucous membrane may remain, and sickness, diarrhoea or pain may continue in the stomach and intestine although the irritant is no longer present within them, just as the flow of tears and desire to rub may remain in the eye after the piece of grit which has occasioned it may have been removed. The condition which remains after the irritant has been removed is one of inflammation more or less intense. The process of inflammation is a defensive one, but if carried too far may prove injurious.

For the purpose of checking the inflammatory processes and lessening discharge from mucous membranes astringents are employed. Some of these are of mineral and some of vegetable origin, but they almost all possess one chemical property in common, namely, they precipitate albumin. This power is possessed alike by a glass of brandy, by solution of lime, soluble salts of zinc, copper, or silver, by tannic and gallic acids, as well as vegetable juices and extracts which contain them. The strength of the astringent application and the mode of its administration are varied according to the delicacy and position of the mucous membrane affected. Thus to the eye we may use a solution of sulphate of zinc of half a grain to the ounce, while to the ear, urethra or vagina a solution of four to eight grains or even more may be applied. For the stomach and intestines we employ the same drug in the form of a pill; and when it is desired to act especially upon the intestines, the pills are made of a harder consistence or less soluble preparation, or are covered with keratin, so that they may not act much, if at all, upon the stomach while passing through it before reaching the intestines. The heat which occurs in inflamed parts is chiefly due to the larger amount of blood circulating in the part on account of the dilatation of the vessels. The pain is due to stretching of the nerve fibrils or compression of them by the turgid vessels in the swollen tissues. This latter cause is chiefly observed when the tissues are of a very unyielding character; for example, when the inflammation occurs in a bone or under a thick fibrous and unyielding membrane. The swelling, heat and pain may sometimes be relieved by mere change of position altering the flow of blood to the inflamed part. Thus when inflammation occurs in the finger, as in a whitlow, the pain is not only constantly severe, but it is increased by every pulsation of the heart, and thus has a throbbing character. By raising the hand nearly to a level with the head both the constant pain and the severity of the throbs may be relieved, as the blood is not sent with such great force into the arteries and returns more readily through the veins. In other parts of the body the same relief may be obtained by raising the inflamed part as high as possible. Relief is frequently given also by both heat and cold, and at first sight it seems strange that agents having such an opposite action should each produce a similar effect. The reason probably is that the application of cold causes contraction of the arteries leading to the inflamed part, while heat by dilating the vessels around forms a side channel through which the blood passes, the tension in the seat of inflammation being thus lessened in both cases. When the inflammation occurs in soft parts where the surrounding vessels can be readily dilated, heat often affords more relief to the pain than cold, but when the inflammation is in a bone or in unyielding fibrous tissues, cold generally gives more relief. For example, the pain of a gum-boil is generally relieved more by warmth, because the yielding tissues of the gum, mouth and cheek can be readily relaxed by heat and their vessels dilated; but when the pain is dependent upon inflammation in the hard unyielding socket of a tooth, cold generally gives greater relief. The removal of blood, either by incision or by the application of leeches, sometimes gives considerable relief to the pain and tension of inflamed parts. Blisters applied at some distance from inflamed parts are also sometimes useful; and probably they produce this good effect by causing a reflex contraction of the arteries in the inflamed part, and thus acting like a cold application. Certain drugs have the power of relieving inflammation by slowing the heart and rendering its impulse more feeble. Amongst those are to be classed small doses of aconite and colchicum; the former especially tends to lessen the process of inflammation generally, when it is not too severe. There can be little doubt that the intensity of inflammation frequently depends very much on the condition of the blood, and that by altering the blood inflammation may be lessened. Thus free purgation, and especially purgation by cholagogues and salines, has long been recognized as a useful means of reducing the inflammatory process. For example, a mercurial pill at night, followed by salts and senna in the morning, will often relieve the pain in toothache or gum-boil, and lessen inflammation not only in the mouth, but other parts of the body as well. Such remedies are termed *antiphlogistic*. Venesection (blood-letting) at one time was highly esteemed as an antiphlogistic measure, and while it is possible that it has now fallen too much into disuse, there can be no doubt that at one time it was very greatly abused, and was carried to such an excess as to kill many patients who would have recovered perfectly had they been let alone. Although the high temperature in an inflamed part is chiefly due to the increased circulation of blood in it, yet the presence of inflammation appears to cause increased formation of heat either in the inflamed part itself or in the body generally, because we rarely find inflammation exist to any extent without the temperature of the body being raised and a febrile condition produced.

Two very old remedies for fever are acetate of ammonia and nitrous ether. These were formerly given empirically, simply because they had been found to do good. Now we can see the reason for their administration, because the nitrous ether, consisting chiefly of ethyl nitrite, dilates the superficial vessels and thus allows greater escape of heat from the surface; while acetate of ammonia, by acting as a diaphoretic and stimulating the secretion of sweat, increases the loss of heat by evaporation. When a patient is covered with several blankets, loss of heat from the surface both by radiation and evaporation is to a great extent prevented, but if a cradle be placed over him, so as to raise the bedclothes and allow of free circulation of air around his body, both radiation and evaporation will be increased and the temperature consequently lowered. If his body be left uncovered except by the sheet or blanket thrown over the cradle, the loss of heat is still greater, and it may be much increased by sponging the surface with either hot or cold water so as to leave it slightly moist and increase evaporation. The temperature may be still further reduced by placing vessels filled with ice inside the cradle. When the patient is very restless, so that cradling is impossible, a wet pack may be employed, a sheet wrung out of cold water being wrapped round him, and over this a blanket. The pack has the double effect of restraining his movements and thus lessening the production of heat, while at the same time it dilates the vessels of the skin and produces loss of heat. The restraint which it imposes and the equal distribution of heat over the surface frequently cause sleep quickly in patients who have previously been wildly delirious and entirely sleepless. When the temperature continues to rise in spite of wet sponging and cradling, recourse must be had to the cold bath. The bath should be brought to the bedside and the patient, wrapped in a sheet, should be lifted into it by two attendants. The water should be at the temperature of 90° and gradually reduced by the removal of hot water and displacement by cold, until the temperature of the patient as taken in the mouth is reduced to about 99½° or 99°. After this the patient should be taken out and again put into bed. It is inadvisable to lower the temperature quite to the normal while the patient is in the bath, as frequently it falls after his removal, and may fall so far as to induce collapse. In cases where no bath is available a large mackintosh sheet may be spread upon the bed under the patient, the sides and top may be raised by pillows, and cold water may be applied to the surface of the body with large sponges. The mackintosh sheet forms a shallow bath, and the water may afterwards be run off from it at the lower end of the bed. Another way of applying cold is to dip an ordinary sheet into cold water, apply it for three or four minutes to the surface of the body, then remove it and replace it by another sheet while the first one is being dipped in water. By the alternate use of the two sheets, or by the use of one quickly wrung out of cold water as soon as it becomes warm, the patient's temperature may be rapidly reduced.

Fever.

There are a number of drugs which have a very powerful action in lowering temperature. Most of these belong to the aromatic group of bodies, although one of them, antipyrin, belongs rather to the furfurol group. Carbolic acid has an antipyretic action, but on account of its poisonous properties it cannot be employed as an antipyretic. Salicylic acid has a strong antipyretic action, and is most commonly used in the form of its sodium salt, which is much more soluble than the acid itself. Amongst other antipyretics, the most important are quinine, phenacetin and antifebrin. These probably lessen fever by their action upon the nerve centres which regulate the temperature of the body, and partly by their peripheral action in causing the secretion of sweat. Very high fever in itself will cause death, the fatal temperature in rabbits being 114·6°. Before death occurs the pulse and respiration become exceedingly rapid and weak, and complete unconsciousness sets in. That these symptoms are simply due to heat is shown by the fact that if the temperature be quickly reduced by the application of cold the symptoms at once subside. But the delirium which is common in fever, although it may be partly due to rise of temperature, is very often due to poisons in the blood, for in some cases it occurs with quite a low temperature, 101° or 102°, whereas in others the temperature rises to 104° and 105° with no delirium whatever. The presence of toxins in the blood not only affects the brain, causing delirium, but also other organs, the heart and lung, and may cause fatal syncope or respiratory failure.

Anti-toxins and anti-serums. Many years ago Dr S. L. Mitchill (1764–1831) pointed out in America the resemblance which exists between symptoms of poisoning by snake venom and infective fevers.[1] S. Weir Mitchell and others have shown that serpent venom consists chiefly of albumoses, and the toxins formed by infective bacilli have a somewhat similar chemical nature. Calmette and Fraser found that when small doses of snake venom, insufficient to cause death, are injected into an animal, temporary disturbance is produced; but after a few days the animal recovers, and a larger dose is then required to produce any symptoms. By gradually increasing the dose the animal becomes more and more resistant, until at last a dose fifty times as great as that which would at first have produced immediate death can be injected without doing the animal any harm. If a horse be chosen for the experiment, a considerable quantity of blood may be withdrawn without injuring the animal. When this is clotted the serum is found to act as an anti-venin, so that when mixed with the venom of a snake it renders it harmless. Although this result is best obtained when the venom and serum are mixed in a glass before injection, yet if they be injected at the same time in different parts of the body the animal will still be protected and the poison will not produce its usual deadly results. What occurs with snake venom takes place also when the toxins are formed by microbes, and a new method of treatment by anti-toxic serums has been introduced of late years with great success. This is most commonly and successfully used in the treatment of diphtheria. This disease depends upon the presence of a bacillus which grows rapidly at the back of the throat and in the air-passages specially of children, causing the formation of a membrane which, by plugging the windpipe, causes suffocation and death. At the same time it produces a poison which causes inflammation of the nerves, leading to paralysis, which sometimes proves fatal. By growing this bacillus in broth a toxin is formed which remains in solution and can be separated from the bacilli themselves by filtration. This toxin-containing broth is injected into a horse in increasing doses, just as in the case of the serpent venom, and after the resistance of the horse has been much increased it is bled into sterilized vessels and the blood is allowed to coagulate. The serum is then removed and its anti-toxic power tested by ascertaining the amount necessary to counteract a given amount of active toxin in a guinea-pig of a certain size, the standard weight being three hundred grammes. The serum, the strength of which has thus been ascertained, is distributed in bottles and injected in the proper quantity under the skin of children suffering from diphtheria. If used at an early stage of the disease, and in sufficient quantity, the results are wonderful. The same method of serum therapeutics has been used in other infective diseases, but not with the same success.

Inoculation. Another therapeutic method which is historically much older than that of serum therapeutics is that of inoculation. The virulence of infective diseases varies in different epidemics, and at different times in the same epidemic. It had been noted that many infective diseases did not attack an individual a second time, the first attack appearing to protect from subsequent ones. The idea of inoculation, therefore, was to infect an individual with a mild form of the disease, so that he should escape infection by a more virulent one. This was tried largely in the case of smallpox, and once at least by Dr Erasmus Darwin in the case of scarlet fever. The worst of this method was that the disease thus inoculated did not always prove of a mild character, and in the case of Dr Erasmus Darwin's son the scarlet fever was exceedingly severe and very nearly proved fatal. To Edward Jenner we owe the discovery that vaccination protects against smallpox, and it is now generally acknowledged that smallpox and vaccine are probably the same disease, the virus of which is modified and its virulence lessened by passing through the body of the cow. Pasteur found that the germs of anthrax could be cultivated outside the body and their virulence weakened either by growing them at too high a temperature or in an unsuitable medium. By inoculating first with a weak virus and then with others which were stronger and stronger, he was able completely to protect oxen either from the effects of inoculation with the strongest virus or from infection through contact with other animals suffering from the disorder. On the other hand, he found the weakened virus could be again strengthened by inoculating a feeble animal such as a guinea-pig a day or two old with it, and then inoculating stronger and stronger animals: an increase in strength was gained with each inoculation, until at last the virus could attack the strongest. A similar increase in virulence appears to occur in plague, where animals, especially rats and mice, seem to be affected before human beings, and not only increase the virulence of the microbes, but convey the infection. Two methods of protective inoculation have been used. In one, Haffkine employs the toxins obtained by growing plague bacilli in broth for five or six weeks, and then heating the whole to 65° or 70° C. so as to destroy the bacilli. This preparation is prophylactic, but does not seem to be curative. Yersin has prepared a serum from horses in the same way as diphtheria anti-toxin, and this is said to have a curative action during the attack. In the same way sterilized cultures of typhoid bacilli have been used to protect against attacks of typhoid fever, and an anti-typhoid serum has been employed with intent to cure. Protection does seem to be afforded, but the curative action of the serum is still somewhat doubtful. Although the anti-toxins which are used in the cure of infective diseases are not dangerous to life, yet they sometimes cause unpleasant consequences, more especially an urticarial eruption almost exactly like that which follows eating mussels or other shell-fish. Sometimes the swelling of the skin is much more general, so that the whole body may be so swollen and puffy as exactly to resemble that of a person suffering from advanced kidney disease. These disagreeable results, however, are not to be compared with the benefits obtained by the injection of anti-toxic serum, and this method of treatment is likely to maintain its place in therapeutics.

Organo-therapeutics. For many years pepsine has been used as a remedy in dyspepsia to supplement the deficiency of digestive juice in the stomach, and it has been used popularly in dyspepsia for a still longer period. From time immemorial savages have been accustomed to eat the hearts of lions and other wild animals, under the belief that they will thereby obtain courage and strength like that of the animal from which the heart had been taken, but in 1889 Brown-Séquard proposed to use testicular juice as a general tonic and stimulant. Observations were made on the connexion between thyroid gland and myxoedema, which appeared to show that this disease was dependent upon atrophy of the gland. Accordingly the liquid extracts of the gland, or the gland substance itself compressed into tablets, have become largely used in the treatment of the disorder. The success which has been achieved has led to the use of many other organs in a raw or compressed form, or as extracts, in other diseases; *e.g.* of suprarenal capsule in Addison's disease, of bone marrow in pernicious anaemia, of thymus and suprarenal capsule in exophthalmic goître, of kidney in renal disease, and of pituitary body in acromegaly. To this method of treatment the name of organo-therapeutics or opo-therapy has been given. The first scientific attempt to employ portions of raw organs in the treatment of disease was made by Lauder Brunton in diabetes in 1873, sixteen years before Brown-Séquard's paper on the effect of testicular juice. From considering the nature of diabetes, he had come to the conclusion that many cases were due to imperfect oxidation of sugar in the body; that this oxidation was normally carried out by a ferment in the muscles, and that probably the disease was in some cases dependent upon absence of the ferment. He tried to supply this by giving raw

[1] Quoted by Weir Mitchell, "Researches on the Venom of the Rattlesnake," *Smithsonian Contributions* (1860), p. 97.

meat and glycerine extract of meat, but although he seemed to get some benefit from the treatment, it was not sufficiently marked to attract general attention. His attempts to isolate a glycolytic ferment from flesh were also only partially successful. One of the great difficulties in the way of applying this treatment is that in all probability many of the ferments or enzymes are altered during the process of absorption in the same way as the normal ferments of digestion, and unless the tissue enzymes can be isolated and injected subcutaneously the desired results will not be obtained. The most striking of all the results of organo-therapy are those obtained in myxoedema. In this disease the face is heavy, puffy and expressionless, the lips thick, the speech slow, the hands shapeless and spade-like, the patient apathetic, the circulation slow and the extremities cold. Under the influence of thyroid gland these symptoms all disappear, and the patient is frequently restored to a normal condition. When the thyroid gland is absent in children, not only is the expression of the face dull and heavy as in the adult, but the growth both of body and mind is arrested, and the child remains a stunted idiot. The effect of thyroid gland in such cases is marvellous, the child growing in body and becoming healthy and intelligent. In the case of the thyroid the function of the gland appears to be to prepare a secretion which is poured out into the blood and alters tissue-change. When the thyroid tablets or extract of thyroid are given in too large quantities to patients suffering from myxoedema, the symptoms of myxoedema disappear, but in their place appear others indicative of increased metabolism and accelerated circulation. The pulse-rate becomes very rapid, the extremities become warm, so that the patient is obliged to wear few clothes, the temper becomes irritable, the patient nervous, and a fine tremor is observed in the hands. On stopping the administration of thyroid these symptoms again disappear. When the thyroid is hypertrophied, as in Graves's disease, the same symptoms are observed, and these are probably due to increased secretion from the thyroid. At the same time other symptoms, such as exophthalmos, may appear, which have an independent origin and are not due to the secretion of the gland. The whole of the secretion here is poured into the blood and not at all on to a mucous surface, and herein the thyroid gland differs largely from such glands as the pancreas or peptic and intestinal glands. But it seems now probable that all glands which have what may be termed an external secretion like the pancreas, stomach, intestine, skin and kidneys have also an internal secretion, so that while they are pouring out one secretion from the ducts into the intestine or external air, they are also pouring into the lymphatics, and thus into the blood, an internal secretion. In fact, a splitting appears to take place in the process of secretion somewhat resembling that which takes place in the formation of a toxin and anti-toxin. The secretion of some digestive glands would prove poisonous if absorbed unchanged. For example, the trypsin of the pancreas (see NUTRITION) digests albuminous bodies in neutral or alcoholic solution, and if the whole of that which is secreted in the pancreas for the digestion of meat in the intestine were absorbed unchanged into the circulation, it would digest the body itself and quickly cause death. The secretion of trypsin by the pancreas may therefore be looked upon as the formation of a toxin. We do not know at present if any corresponding anti-toxin or anti-trypsin, as we may term it, is returned into the lymphatics or blood from the gland, but the pancreas, which in addition to secreting trypsin secretes a diastatic ferment forming sugar from starch, pours this into the intestine and secretes at the same time a glycolytic ferment which breaks up sugar, and this latter passes into the blood by way of the lymphatics. Thus the gland not only breaks up starch into sugar in the intestine, but breaks up the sugar thus formed after it has been absorbed into the blood. It is known that several, perhaps very many, if not all glands have also the power of secreting substances to which Starling has given the name of "hormones." These pass into the blood and cause other glands to secrete. Thus an acid in the duodenum causes it to secrete a hormone to which the name of "secretin" has been given. This passes to the pancreas and causes increased secretion from that gland. It is probable that the pancreas in its turn also secretes something which activates a ferment in the muscles. It is evident therefore that the connexion between the different glands of the body is a very complicated one and that the effects of a drug which acts upon any one of them may be of a very far-reaching character. It is by no means improbable that all glands have a double or even triple function, and that sometimes the external may be even less important than the internal secretion. On this point, however, we have but little definite knowledge, and a great field is open for future research. At the same time, there are many indications of the importance of an internal secretion in popular treatment. For example, there are many people who feel very much better after profuse perspiration, and as sweat appears to contain little but water and a few salts, it is not improbable that the improvement in their condition is due rather to the internal secretion from the skin than to the elimination effected by the sweat. It is probable that the kidneys also have an internal secretion, and that the great oedema sometimes found in kidney disease is rather due to the action of some proteid body resembling in its effects the streptococcus anti-toxin, than to accumulation of water due to imperfect action of the kidney. Similarly the beneficial effects of purgation may be due not only to the elimination which takes place through the bowel, but also to the internal secretion from the intestinal glands.

The health of the body depends upon the proper kind and supply of food, upon its proper digestion and absorption, on the proper metabolism or tissue-change in the body, and the proper excretion of waste. We have considered how these may be disturbed by microbes from without and from within. We have also considered in a general way the treatment of local diseases by passive protection, active protection and repair of waste; but both maintenance of health and repair of waste depend very largely upon the condition of the blood. When this is healthy the attacks of microbes are resisted, wounds heal readily, and patients recover from serious diseases which in persons of debilitated constitution would prove fatal. In order to keep the blood in a satisfactory condition it must be well supplied with fresh nutriment, and the products of waste freely eliminated. The food required for the body may be divided into five kinds—carbohydrates, such as starches and sugars; fats; proteids, such as meat and eggs; salts; and last, but not least, water.

Nutrition and elimination.

Water forms almost three-fifths of the weight of the body, so that it amounts to more than all the other constituents put together. Without it life would be impossible, and it is well recognized that death from thirst is more awful than death from hunger. The healthy organism can adapt itself to great varieties both in regard to the quality and quantity of food; but when health begins to fail much care may be required, and many ailments arise from dyspepsia. Imperfect digestion is very often caused by defective teeth or by undue haste in eating, so that the food is bolted instead of being sufficiently masticated and insalivated. The food thus reaches the stomach in large lumps which cannot be readily digested, and either remain there till they decompose and give rise to irritation in the stomach itself, or pass on to the intestine, where digestion is likewise incomplete, and the food is ejected without the proper amount of nourishment having been extracted from it; while at the same time the products of its decomposition may have been absorbed and acted as poisons, giving rise to lassitude, discomfort, headache, or perhaps even to irritability and sleeplessness. Much dyspepsia would be avoided by attention to the condition of the teeth, by artificial teeth when the natural ones are defective, and by obedience to one or two simple rules: (1) to eat slowly; (2) to masticate thoroughly; (3) to take no liquid with meals excepting breakfast, but sip half a pint of hot water on rising in the morning, on going to bed at night, and again about an hour before luncheon and dinner. The object of taking no liquid with meals is that it ensures mastication being more complete, because persons cannot wash the unmasticated food down by drinking, and it prevents the gastric juice from being greatly diluted, and so allows it to digest more rapidly. Should these rules be insufficient, then (4) proteid and farinaceous food should be taken in separate meals—farinaceous food at breakfast, proteid alone at lunch; farinaceous in the afternoon, and proteid again in the evening. The reason for this is that farinaceous foods are digested in the intestine and not in the stomach, where they may undergo fermentation, whereas proteid foods are to a great extent digested in the stomach. When the secretion of gastric juice is deficient it may be excited by gastric tonics, such as ten grains of bicarbonate of soda and a drachm of compound tincture of gentian in water shortly before meals, and may be supplemented by the administration of pepsin and hydrochloric acid after meals. When the nervous system is below par, and both secretion and movements are deficient in the stomach, nervine tonics, such as nux vomica or strychnine, are most useful.

Sleeplessness. High tension in the arteries is often associated with sleeplessness, the pressure of blood being such that the circulation in the brain is constantly maintained at a high rate of speed and the brain is unable to obtain rest. The means of producing sleep may be divided into two classes: those (1) which lessen the circulation, and which (2) diminish the excitability of the brain cells. The circulation in the brain may be lessened by warmth to the feet, cold to the head, warm food in the stomach, warm poultices or compresses to the abdomen, antipyretics, which reduce the temperature and consequently slow the beats of the heart in fever, and cardiac or vascular tonics, which slow the heart and tend to restore tone to the blood-vessels, so that the circulation in the brain may be more efficiently regulated. Amongst those which lessen excitability of the brain-cells are opium, morphine, hyoscyamus, chloral, sulphonal, trional, paraldehyde, chloralamide, chloralose, hop and many others. A combination of the two kinds of remedy is sometimes useful, and chloral sometimes succeeds when other things fail, because it depresses the circulation as well as lessens the activity of the brain-cells.

Pain. Irritation of sensory nerves tends to cause contraction of the vessels and to raise the blood pressure, and where pain is present opium or morphine is the most efficient sedative. The sensation of pain is felt in the brain, and the cause of it may be in the sensory centres of the brain alone, as in cases of hysterical pain, with no lesion to cause it. Ordinarily, however, it is due to some peripheral irritation which is conducted by sensory nerves to the spinal cord and thence up to the sensory centre in the brain. Pain may be stopped by removing the cause of irritation, as, for example, by the extraction of a carious tooth or by rendering the nerve-endings insensitive to irritation, as by the application of cocaine; by preventing its transmission along the spinal cord by antipyrin, phenacetin, acetanilide, cocaine, &c.; or by dulling the perceptive centre in the brain by means of opium or its alkaloids, by anaesthetics, and probably also, to a certain extent, by antipyrin and its congeners.

High tension. Both sleeplessness and pain are sometimes due to the action of toxins absorbed from the intestine, and both of them may sometimes be relieved more efficiently by thorough purgation than by narcotics. Another condition which is probably due to toxins is high pressure within the arteries. When this continues for a length of time it tends by itself to cause deterioration of the blood-vessels and leads to death either by cerebral apoplexy or by cardiac failure. It is therefore very important to discover high tension at an early period. It may be diminished or its increase prevented by a diet from which red meat and meat extracts are excluded, by the use of the lactic acid bacillus, by the administration of laxatives and cholagogues to regulate the bowels, and by the use of iodides and nitrites. By such régime and medicines life may sometimes be prolonged for many years.

Deficient nervous action also leads to defective secretion and movement in the intestine, sometimes with flatulent accumulation and sometimes with constipation. In such cases nux vomica or strychnine is useful. *Flatulence.* Flatulent distension in the stomach or bowels is partly due to air which has been swallowed and partly to gas which has been formed by the decomposition of food. The stomach may become distended with gas on account of acid fermentation leading to the frequent swallowing of saliva, and both this form of flatulence and that caused by the actual formation of gas are much diminished by such drugs as tend to prevent fermentation. Amongst the best of these are carbolic acid in doses of one or two grains, creosote in one or two drops, and sulpho-carbolate of soda in doses of ten grains. Others which may be mentioned are salicylate of bismuth, salol, β-naphthol and naphthalene. By preventing fermentation in the intestine these also tend to prevent or check diarrhoea, and they may do good after the irritant has been removed by castor oil. After the irritant has been removed and fermentation stopped, the irritation still remaining in the intestinal wall may be soothed by chalk mixture and bismuth, to which if necessary small quantities of opium may be added. In cases where diarrhoea is very obstinate and lasts for weeks, sulphuric acid is sometimes more efficacious than alkalis; and in chronic colics it may be necessary to treat the mucous membrane by local application of astringent solutions. For this purpose solutions of sulphate of copper or of nitrate of silver may be gently introduced into the bowel in quantities of a quart at a time. It is essential that a large quantity should be used, as otherwise the seat of irritation may not be reached by the astringent. Flatulence and diarrhoea as well as many general disorders are often due to intestinal depression caused by microbes. To these injurious microbes Metchnikoff has given the name of "wild," and he proposes to restore health by giving "tame" microbes, such as lactic acid bacilli. This treatment on the principle of "setting a thief to catch a thief" is frequently very useful. The lactic acid bacilli are given either in the form of tablets or milk soured by them, or cheese made from the sour milk. The most efficient form is soured milk, which acts as a food as well as medicine.

Constipation. Constipation is so common that it may be almost looked upon as the normal condition in civilized countries. Two of its chief causes probably are (1) improvement in cookery, whereby the harder and more irritating parts of the food are softened or removed; and (2) improvement in grinding machinery, whereby the harder and more stimulating parts of the grain are separated from the finer flour which is used for bread. In consequence of the absence of mechanical stimulant the bowels act more slowly, and constipation is the result. It may be considerably diminished by a return to a more natural system of feeding, as by using brown bread instead of white, by taking oatmeal porridge, and by eating raw or cooked fruits, such as apples, oranges, prunes and figs, or preserves made of fruit, such as raspberry and strawberry jam, marmalade, &c., by vegetables or by dried and powdered seaweed. Should these means fail, aperients may be used. The commonest are senna in the form of compound liquorice powder, sulphur in the form of lozenges, cascara sagrada, either in tablets or in the form of liquid or dry extract, rhubarb, colocynth and especially aloes. The last acts chiefly upon the lower bowel, and forms a constituent of nearly every purgative pill. The medicines above mentioned may be taken either in a moderate dose at bedtime or in the form of a dinner pill, or they may be taken in small doses three times a day just before or after meals. Some sufferers from constipation find that they get greater relief from salts dissolved in water, or from natural aperient water taken on rising in the morning, and others again find that the best way of opening the bowels is to inject one or two drachms of glycerine into the rectum, or use it as a suppository. If these means fail, exercise, massage and electricity may help a cure.

The most common diseases of malassimilation (or "metabolic" diseases) are gout, rheumatism and diabetes. In health most of the nitrogenous waste in the body is eliminated as urea, but in gout uric acid is either formed in too great quantity or too little is eliminated, so that it tends to be deposited as urate of soda in the joints and other tissues. Two means of treating it by diet have been proposed. One is to put the patient on an almost complete vegetarian diet, so as to limit both the amount of uric acid introduced into the body as well as its formation in the body. The other plan is to use an exclusively meat diet, combined with the ingestion of a large quantity of hot water, so as to cause free elimination. Where neither method is strictly pursued it is usual to forbid to gouty patients sugar, pastry and pickles, and to forbid heavy wines, especially Burgundy and port. During an attack of acute gout nothing relieves so much as colchicum, but during the intervals potash or lithia salts taken in water are advisable, as tending to prevent the deposits of urate of soda. In true diabetes, which probably originates in the central nervous system, or in disease of the pancreas, as well as in the glycosuria common in gouty patients, sugar in every form should be entirely forbidden, and starchy food restricted to within narrow limits. The remedy most trusted to in this disease is opium and its alkaloids, morphine and codeine. In acute attacks of rheumatism the remedy *par excellence* is salicylate of soda, which reduces the temperature, relieves the pain, and removes the swellings from the joints. Rest in bed should be insisted upon for a longer time than appears actually required, because acute rheumatism tends to bring on cardiac changes, and is more likely to do this when the heart is excited than when the patient is kept at rest. In chronic rheumatism the chief remedies are salicylate of soda, and its allies iodide of potassium, guaiacum and sulphur, while massage, liniments and baths are beneficial as local applications.

Diseases of mal-assimilation.

Elimination of waste-products is one of the most important points in regard to health, and when this is interfered with by disease of the kidneys, the life of the patient is rendered more or less uncertain and the health frequently seriously impaired. In some cases of chronic inflammation of the kidneys, where the disease is not extensive, the patient may continue in fair health for a number of years, provided attention be paid to the following rules:—(1) The body must be kept warm, and chills must be scrupulously avoided; (2) the digestion must be attended to carefully, so that no excess of poisonous bodies is formed in the intestine or absorbed from it; (3) eliminating channels such as the skin and bowel must be kept active. It is usual to reduce the quantity of proteid food to a minimum, in order to lessen the amount of nitrogenous waste to be excreted by the kidneys. Sometimes an entirely milk diet is useful, but in others it does not agree, and a more liberal diet is essential. Alcohol should be avoided as much as possible. The small contracted kidney, which is so common in elderly gouty people, is usually associated with a very large secretion of urine containing only a minute trace of albumin. The tension within the blood-vessels is generally high, and the patients run a risk of anginal attacks or of apoplexy. A nearly vegetarian diet and a complete abstinence from alcoholic stimulants is the ideal in such cases, but it must be modified to suit individuals, as sometimes very strict limitations prove injurious. The daily use of potash, and especially nitrate of potash, tends to reduce the tension and increase the patient's safety, but if pushed too far may sometimes render him very weak and depressed.

Diets and "cures."

It has already been mentioned that water is absolutely necessary for the body: by taking it hot it does not lie like a weight on the stomach, and by taking it an hour before meals it washes out the remnants of the previous meal; and being absorbed into the blood, it probably renders the secretion of gastric juice freer and accelerates digestion, instead of diluting it and interfering with the digestive processes. Where the stomach and bowels are irritable, all food likely to cause mechanical irritation should be avoided, such as skins, bones, fibres and seeds. In some cases of diarrhoea an entirely milk diet has to be prescribed, and in the diarrhoea of children it is sometimes necessary to alternate a diet of barley water with one of beef juice or white of egg and water, or to give whey instead of milk. The drinking of large quantities of whey is used as a means of cure for dyspepsia in adults, and also in cases of chronic bronchitis. The whey is drunk warm, and for this cure it is usual to go to some Alpine resort where pasturage is abundant and fresh milk can be had at all times of the day. The cure is greatly helped by the fresh air and sunshine of such places, among which are Interlaken, Rigi-Scheideck and Weggis in Switzerland; Ischl and Meran in Austria; Harzburg, Reichenhall and Sanct Blasien in Germany. Another therapeutic method is the so-called "grape cure," in which, along with a regulated diet, five or six pounds of grapes are eaten daily. As the grapes contain a quantity of water and of salts, they tend to lessen the amount of food taken, to increase the action of the bowels, and to stimulate the kidneys. The "grape cure" is used both in chronic disease of the stomach and intestines with or without constipation, and also in cases of gout or ailments depending upon a gouty constitution. The chief places where it is carried on are in the neighbourhood of the Rhine, on the Lake of Geneva and in Tirol. Amongst places in the Rhine and its vicinity may be mentioned Kreuznach, Neustadt, Rüdesheim and St Goar; on the Lake of Geneva are Montreux and Vevey; and in Tirol Gries and Meran. The so-called "Salisbury" cure consists of living entirely upon minced beef and hot water. It sometimes answers very well in persons troubled with flatulence, since meat does not give rise to the same amount of gas in the intestines as carbohydrates. During its continuance fat is absorbed from the subcutaneous tissue, and patients become very much thinner, so that it not only lessens flatulence, but reduces obesity. It is, in fact, very much the same system as that proposed a number of years ago by Banting (see CORPULENCE). It is very important for those who are trying this diet to bear in mind the necessity of abundance of water, because sometimes they may be tempted to lessen the water on account of the inconvenience produced either by frequent micturition or too profuse sweats. If the meat diet be continued with too small a proportion of water, a gouty condition may be brought on. This diet has been recommended in gout, and no doubt the essential part of it is the hot water, but there can be little doubt that in fat gouty people it is often useful. An entirely opposite dietary is that in which butcher's meat is completely excluded and proteids reduced to a minimum, as advocated by Dr Haig. This dietary also is very useful in gout, but it answers better in thin gouty people than in fat ones.

The dietaries already mentioned, the whey cure, the grape cure, the meat cure and the vegetarian cure, are all more or less systems of starvation, one or other article of ordinary diet being either reduced to a minimum or omitted altogether. In three of them at least—the whey cure, the grape cure and the meat cure—a diminution in one or other of the solid constituents of food is associated with the ingestion of an unusually large quantity of water. In visiting the most famous watering-places, it is curious to note how one finds, in the various waters, here some chloride, there some sulphate, here some potash, there some magnesium, but in all of them we find water. In watching the troops of patients who go to the wells we notice that most of them do more early rising, take more regular exercise, and drink more water in the course of a month at the well than they would do in the rest of the year at home. The watering-places divide themselves, according to the temperature of the waters, into cold and thermal, and according to the composition of the waters, into purgative saline, indifferent saline, sulphur and iron. Amongst the most celebrated saline waters are those of Carlsbad, which contain sulphate of soda and bicarbonate of soda. These salts crystallize out when the water is partially evaporated and may be used with hot water at home, the best imitation of the Carlsbad water being obtained by mixing with hot water the powdered Carlsbad salts (*pulverförmig*), which contain all the constituents of the natural water. Where it is impossible for the patient to visit Carlsbad, half a teaspoonful or a teaspoonful of salt may be taken in a large tumbler of hot water on rising every morning; but when taken at home the treatment is not so effective as at Carlsbad, because at the wells sipping water is associated with early rising, considerable exercise and a very carefully regulated diet. It is, indeed, the care with which the diet of patients is regulated and the difficulty that patients find in obtaining forbidden foods at hotels and restaurants, that make Carlsbad better for the liver than any other watering-place. Amongst other places having a similar action are Marienbad, Franzensbad and Tarasp. The waters just mentioned contain free alkali as well as sulphates, and are employed more especially in cases of hepatic disorder, such as congestion of the liver, jaundice, gall-stone and diabetes. A number of other waters containing sulphides and chlorides are powerfully purgative, and are more often drunk at home than at the springs. Amongst these are the Hungarian waters, Aesculap, Apenta, Franz Josef and Hunyadi Janos; and the Rubinat and Condal waters of Spain. Waters which have a similar composition are drunk at the springs of Leamington and Cheltenham in England, Brides Salins and St Gervais in France, for chronic constipation, dyspepsia, gout and hepatic disorders of a milder character than those usually treated at Carlsbad. The waters in which chlorides form the purgative principle are those of Homburg, Kissingen, Wiesbaden and Baden Baden in Germany, and Bridge of Allan in Scotland. Similar waters, but much weaker, are found at Innerleithen and Pitkeithly. Sulphur waters are chiefly used for painful and stiff joints, chronic skin disease, and chronic catarrhal affections. The most important are Aix-les-Bains, and a number of springs in the Pyrenees in France, Aachen in Germany, Harrogate in England, Strathpeffer and Moffat in Scotland. Iron waters are used in anaemia and the affections which are frequently associated with it. The most important are Spa in Belgium, Schwalbach in Germany, St Moritz and Tarasp in Switzerland. Iron waters are, however, common, and are generally found at all those places which have sulphur waters. Simple alkaline waters containing carbonates, chiefly of sodium along with some magnesium and calcium, are drunk for their utility in gastric and intestinal disorders as well as in rheumatism and gout. They are also employed locally as sprays and douches to the nose, throat, vagina and rectum, for catarrhal conditions of the mucous membranes. The most important are Vichy and Vals in France and Neuenahr in Germany. Alkaline waters containing a little common salt are perhaps even more important than the pure alkaline, as the salt lessens the depressing effect of the alkali. They are therefore used largely in chronic gout, rheumatism and in calculous affections of the kidney. Amongst the most important are Ems and Wildungen in Germany, Contrexéville and Royat in France.

Simple thermal waters are those which contain only a very small quantity of solids, and owe their efficacy chiefly to their temperature. They are used partly for drinking, but even more so for baths. Bath, Buxton and Matlock in England; Mallow in Ireland; Wildbad, Schlangenbad and Badenweiler in Germany; Gastein and Teplitz in Austria; Ragatz in Switzerland; Plombières and Dax in France; and Bormio in Italy are amongst the best known. When water is dashed against the body with more or less violence, its effects are more powerful than when the body is simply immersed in it. Thus the stimulating effect of sea-bathing is more marked than simple salt-water baths, for in addition to the effect upon the skin produced by the salt and by the temperature of the water, we have the quicker removal of heat by the continual renewal of the water as the waves dash over the body, and mechanical stimulus from its weight and impetus. Somewhat similar effects are produced by so-called wave-baths, and at Nauheim, although the fresh movement of the water against the surface of the body is much less than in the sea, yet its stimulating effect is greatly increased by the presence of carbonic acid in it. Douches have a still more powerful action than waves. They are generally given in the air, but at Plombières very simple douches are given under water. These form a more powerful wave-bath, and in combination with intestinal irrigation, are used very successfully for the treatment of abdominal disorders. Douches to the spine are much employed for nervous debility, and good effects are also obtained in such cases from the so-called needle-bath, where small streams of water at high pressure are driven against the whole surface of the body. In the treatment of stiffened joints, massage under water is very serviceable, and in the so-called Aix douche a nozzle from which water continuously streams is fastened to the wrist of the masseur, so that a current of water is constantly playing upon the joint which he is rubbing. While water containing much saline matter, and more especially water containing free carbonic acid, has a very stimulating action upon the skin, mud has a sedative effect, so that in a mud-bath one feels a pleasant soothing sensation as if bathing in cream. These mud-baths are chiefly employed at Marienbad, Franzensbad and Homburg. Sulphur-baths and sulphur waters are chiefly used in combination for rheumatism and gout, and massage, especially under water, is frequently combined most advantageously with baths and drinking water to effect a cure.

Baths.

Exercises, passive and active, are also used in diseases of the joints, as well as massage and baths, but exercises and training are even more important in cases of cardiac disease. In very bad cases of heart disease, where the patient is unable to go about, the best plan of treatment usually is to make him stay absolutely quiet in bed and have massage, which aids the circulation, tends to remove waste, and increases the appetite. To this is added gentle exercise, beginning with the fingers at first. At Meran walks have been arranged according to Oertel's system, and at Llangammarch in Wales both Oertel's and Schott's systems are employed, and baths according to the Nauheim system are also to be found in London, Sidmouth, Leamington, Buxton, Strathpeffer, &c. Many people who have sedentary employments are unable to get as much exercise as they require because they have not either the time or the opportunity. Such persons may sometimes get a good deal of exercise in a short time by the use of dumb-bells, of elastic cords, or of cords running over pulleys and weighted at one end. The whole system of methodical exercises was started by Ling in Sweden, but it has been developed to a large extent for the purpose of increasing muscular strength by the professional athlete Sandow. A punching ball or rowing machine is even better as being less monotonous. Fencing, boxing or wrestling may also be resorted to. Walking on the flat is of comparatively little use as a mode of exercise, and has become supplanted to a considerable extent by bicycling. Ascending mountains, however, is very different, because in walking up a steep ascent all the muscles of the body are thrown into action, and not only those of the legs. In addition the purer and rarefied air of the Swiss mountains seems to produce a sense of exhilaration which is not felt nearer the sea-level. For those who suffer from nervous depression, exercise in the Swiss mountains is useful, and even living at a height of about 6000 ft. above the sea-level seems to have an exhilarating influence. The nature of this is not very easy to analyse, but as mental depression is closely associated with irritation of the vagus nerve and weakening of the circulation, it seems not at all unlikely that mountain air acts by accelerating the pulse and quickening the circulation, and thus creating a sense of well-being. Indeed, many patients liken its effect to that of drinking champagne. In some persons rarefied air is too stimulating, so that they find difficulty in sleeping, and for those who suffer from insomnia a warm moist air nearer the sea-level is preferable.

Exercise.

It sometimes happens, however, that people cannot sleep at the seaside itself, although they do so perfectly well a mile or two inland. Where the nervous system is exhausted, such warm and moist climates as Malaga, Madeira, Tenerife and Grand Canary are suitable. In these places not only is the air moist, but the temperature is particularly equable, and they are therefore suitable places also for persons suffering from kidney disease. Many such persons also do well in dry, warm places, such as the higher reaches of the Nile, Egypt, Mentone, St Raphaël and other sheltered places on the Riviera. The places mentioned are all suitable for persons suffering from chronic bronchitis, who should avoid any irritation

Health resorts.

of the larynx, trachea or bronchi by air which is too dry or which is liable to great changes of temperature. Some cases of phthisis, therefore, do better in warmer and moist climates, and especially those where the larynx has become affected by the disease. Such patients are apt to suffer much from cough and laryngeal irritation in the cold, dry air of the Alps, whereas they live in comparative comfort on the Riviera, in the Canary Islands, Madeira or at Capri. But warm, moist climates rather favour sedentary habits and tend to lessen appetite, so that the nutrition of the patient is apt to suffer; and although phthisical patients may live in comparative comfort in such climates, their tendency to recovery in them is small. At the Swiss health resorts, on the contrary, during the winter the air is very pure, and has just sufficient coldness to make exercise agreeable to patients. They are thus induced to be out the whole day, and to take food with an appetite which greatly improves their nutrition and aids their restoration to health. The best-known Alpine health resorts are St Moritz and Davos, to which lately Grindelwald has been added. St Moritz is, upon the whole, better for less advanced cases, while Davos is more sheltered and better for cases which are severe. It is a mistake, however, to send those in whom the disease is very far advanced away from home and friends, because when there is no hope of cure it is better for them to die in comfort at home. At the health resorts just mentioned the amount of food taken is regulated by the appetite of the patient himself, but a system of cure has been inaugurated by Dr Brehmer at Görbersdorf, by Dr Dettweiler at Falkenstein, and by Dr Walther at Nordrach, in the Black Forest. The most important point in this treatment consists in forced feeding, the want of appetite which is so prominent in many cases of phthisis being regarded as an abnormal sensation not to be regarded; and under the forced feeding, combined with open-air life, many marvellous recoveries are recorded. Numerous other institutions have been started in Great Britain in imitation of Dr Walther's with a considerable amount of success. Even when patients are unable to stay long at a sanatorium they learn there the advantages of open air and can continue the treatment at home to their great advantage.

In the well-known "rest" cure, which we owe to Weir Mitchell, forced feeding takes a prominent part. The essence of this cure is to give to the patient rest, bodily and mental, by confinement to bed and isolation from the outside world. While this treamcnt by itself would aid recovery from nervous exhaustion, it would lessen appetite and thus interfere with nervous repair; but the want of exertion is supplied by means of massage, which stimulates the circulation and increases the appetite, so that the patient gets all the benefit of exercise without any exhaustion. Where nervous exhaustion is less marked and the Weir Mitchell treatment is not appropriate—for example, in men who are simply overworked or broken down by anxiety or sorrow—a sea voyage is often a satisfactory form of "rest" cure. The lack of posts and telegrams prevents much of the excitement which they would have upon shore, the space for exercise is limited, food is abundant and appetite is supplied by the stimulus of constant exposure in the open air. In order that the voyage should be satisfactory, however, it must be sufficiently long, and the weather must be sufficiently warm to allow the patient to stay in the open air the whole day long. During the heat of summer voyages to the North Cape are suitable, and during the spring and autumn to the Mediterranean, but in the colder months of the year the West Indies, India, Cape Town, Australia or New Zealand forms the best objective.

(T. L. B.)

THERESA, ST (1515–1582), or Teresa de Cepeda, Spanish nun, was born at Avila, in Old Castile, on the 28th of March 1515, and was educated in an Augustinian convent in the town. As a child she was interested in the stories of martyrs, and at the age of eighteen left home one morning, and applied for admission at the Carmelite convent of the Incarnation. She was disappointed at first at the slackness of discipline, but she appears afterwards to have accommodated herself with tolerable success to the worldliness of her environment, though not without intervals of religious misgiving. It was in the year 1554, when she was nearly forty, that the event known as her conversion took place, and the second part of her life began. The death of her father roused her to serious reflection, and one day, as she entered the oratory, she was struck by the image of the wounded Christ, placed there for an approaching festival. She fell in tears at the feet of the figure, and felt every worldly emotion die within her. The shock threw her into a trance, and these trances, accompanied by visions, recurred frequently in the subsequent part of her life. They have since been adduced as Divine attestations of her saintship, but the sisterhood in the convent set them down to possession by a devil; her new departure was due in their eyes to no worthier motive than the desire to be peculiar and to be reputed better than other people. Teresa herself was very humble, and thought their explanation might be true; she took her case to her confessor and to the provincial-general of the Jesuits, who put her under a course of discipline. One day, while thus occupied, her trance came upon her, and she heard a voice say, "Though shalt have no more converse with men, but with angels." After this the trance or fit always returned when she was at prayers, and she felt that Christ was close to her. Presently she was able to see Him, "exactly as He was painted rising from the sepulchre." Her confessor directed her to exorcise the figure, and she obeyed with pain, but, it is needless to say, in vain. The visions grew more and more vivid. The cross of her rosary was snatched from her hand one day, and when returned it was made of jewels more brilliant than diamonds, visible, however, to her alone. She had often an acute pain in her side, and fancied that an angel came to her with a lance tipped with fire, which he struck into her heart. The 27th of August is kept sacred in Spain to this mystery, which has also formed a favourite subject of Spanish painters. She had also visions of another description: she was shown hell with its horrors, and the devil would sit upon her breviary, belabour her with blows, and fill her cell with imps. For several years these experiences continued, and the verdict as to their source still remained far from unanimous. Meanwhile, the spread of the Refcrmation became the subject of much searching of hearts to pious Catholics. Teresa reflected like the rest, and her experience led her to find the real cause of the catastrophe in the relaxation of discipline within the religious orders. She formed the project of founding a house in which all the original rules of the Carmelite order would be observed. In spite of great opposition from the authorities of the order, and in particular from the prioress and sisters of the Incarnation, she persevered with her scheme, being encouraged to appeal to the pope by certain priests who saw the benefit which would accrue to the Church from her zeal. A private house in Avila was secretly got ready to serve as a small convent, and, when the bull arrived from Rome, Teresa went out on leave from the Incarnation and installed four poor women in the new house dedicated to her patron St Joseph. It was on the 24th of August 1562 that mass was said in the little chapel and the new order constituted. It was to be an order of Descalzos or Barefoots, in opposition to the relaxed parent body, the Calzados. The sisters were not to be literally shoeless, but to wear sandals of rope; they were to sleep on straw, to eat no meat, to be strictly confined to the cloister, and to live on alms without regular endowment. After lodging her four sisters, Teresa returned to the Incarnation; but, when the secret was discovered, Carmelites and townspeople were alike furious. Violence, however, was prevented, and the matter was referred to the council of state at Madrid. Philip II. referred it again to the pope, and after six months a fresh bull arrived from Pius V. The provincial of her order now gave her leave to remove and take charge of her sisterhood. The number of thirteen, to which on grounds of discipline she had limited the foundation, was soon filled up, and Teresa spent here the five happiest years of her life. Her visions continued, and, by command of her ecclesiastical superiors, she wrote her autobiography containing a full account of these experiences, though she was far from basing any claim to holiness upon them. The general of the order visited her at Avila, and gave her powers to found other houses of Descalzos, for men as well as women. The last fifteen years of her life were spent mainly in hard journeys with this end and in the continually growing labour of organization. Convents were founded at Medina, Malaga, Valladolid, Toledo, Segovia and Salamanca, and two at Alva under the patronage of the famous duke. Then she had three years of rest, as prioress of her old convent of the Incarnation. She next went to Seville to found a house, thus overstepping for the first time the boundaries of the Castiles, to which her authorization limited her. The latent hostility of the old order was aroused; the general ordered the immediate suppression of the house at Seville, and procured a bull from Gregory XIII. prohibiting the further extension of the reformed houses (1575). But the movement against her came from Italy, and was resented by Philip and the Spanish authorities as undue interference; and after a fierce struggle, during which Teresa was two years under arrest at Toledo, the Carmelites were divided into two bodies in 1580, and the Descalzos obtained the right to elect their own provincial-generals (see CARMELITES). The few remaining years of Teresa's life were spent in the old way, organizing the order she had founded, and travelling about to open new convents. Sixteen convents and fourteen monasteries were founded by her efforts; she wrote a history of her foundations, which forms a supplement to her autobiography. Her last journey of inspection was cut short at Alva, where she died on the 29th of September 1582. A violet odour and a fragrant oil were said to distil from her tomb; and when it was opened nine months afterwards the flesh was found uncorrupted. A hand cut off by a fervent brother was found to work miracles, and the order became convinced that their founder had been a saint. It was resolved in 1585 to remove her remains to Avila, where she was born, the sisters at Alva being consoled by permission to retain the mutilated arm. But the family of the duke of Alva procured an order from the pope enjoining that the body should be restored to Alva, and she was accordingly laid there once more in a splendid tomb. But even then she was not allowed to rest: she was again disentombed, to be laid in a more magnificent coffin, and the greed of reverential relic-seekers made unseemly havoc of her bones.

Teresa was canonized by Gregory XV. in 1622. The honour was doubtless largely due to her asceticism and mystic visions. She called herself Teresa de Jesus, to signify the closeness of her relation to the heavenly Bridegroom, who directed all her actions. Though she deprecated excess of ascetic severity in others, she scourged herself habitually, and wore a peculiarly painful hair-cloth. But her life shows her to have been, besides, a woman of strong practicality and good sense, full of natural shrewdness, and with unusual powers of organization. "You deceived me in saying she was a woman," writes one of her confessors; "she is a bearded man." She was brave in the face of difficulties and dangers, pure in her motives, and her utterances, some of which have been quoted, have the true ethical ring about them. Her MSS. were collected by Philip II. and placed in a rich case in the Escorial, the key of which the king carried about with him. Besides her autobiography and the history of her foundations, her works (all written in Spanish) contain a great number of letters and various treatises of mystical religion, the chief of which are *The Way of Perfection* and *The Castle of the Soul.* Both describe the progress of the soul towards perfect union with God.

Her works, edited by two Dominicans were first published in 1587, and have since appeared in various editions. They were soon afterwards translated into Italian, French (4 vols., Paris, 1840–46) and Latin; an English translation of the *Life* and works (except the letters) by A. Woodhead appeared in 1669. Other translations of the *Life* are those by John Dalton (1851), who also translated *The Way of Perfection* and the *Letters* (1902), and by David Lewis (1870), who in 1871 also translated the *Foundations.* A. R. Waller reprinted Woodhead's translation of *The Way of Perfection* in "The Cloister Library" (1901). Biographies appeared soon after her death by the Jesuit Ribera, who had been her confessor (1602), and by Diego de Yepez, confessor to Philip II. (1599). Details are also given in Ribadeneyra's *Flos Sanctorum* and in Alban Butler's *Lives of the Saints.* A separate biography, with preface by Cardinal Manning, appeared in 1865; a full and critical edition of the *Life* is that by Mrs G. C. Graham, 2 vols. (1894). See also H. Prinz v. Oettingen-Spielberg, *Geschichte d. heil. Theresia* (Regensburg, 1899); A. Whyte, *Santa Teresa, an appreciation, with some of the best passages of the writings* (1897); E. Hello, *Studies in Saintship* (1903).

THEREZINA, a city of Brazil, capital of the state of Piauhy, on the left bank of the Parnahyba river, about 220 m. from its mouth. Pop. (1890) 21,620; for the commune or municipio, 31,523; (1906, estimated), 25,000. It is prettily situated on an open plain and is laid out regularly with broad straight streets with seven large squares. Among its public buildings are the government palace, the legislative and municipal hall, the "Quatro de Setembro" theatre, Misericordia hospital, public market, sanitation and public works, building, courts, police headquarters, barracks, &c. The town is characteristically Portuguese in appearance, its buildings being one or two stories in height, plastered and frequently coloured outside, with large rooms, thick walls, and tile roofs to ensure coolness. There is one lyceum, or high school, with about 400 students, in addition to its primary schools. Its manufacturing industries include a cotton mill, foundry, and soap-works. A steamboat service, with three small boats, maintains regular communication with Parnahyba, near the mouth of the river, besides which there are a number of independent freight-carrying boats. Therezina was founded in 1852, its site being originally called Chapada de Corisco, and was named in honour of the empress, Dona Thereza Christina. It was made the capital of Piauhy in succession to Oeiras.

THERMIDOR (from Gr. θέρμη, heat, and δῶρον, gift), the name given during the French Revolution to the eleventh month of the year in the Republican Calendar. The month fell in the hottest season of the year, beginning on the 19th or 20th of July and ending on the 18th or 19th of August, according to the year. As in all the other months of the Republican Calendar, each of the days of Thermidor was, in accordance with the suggestion of Fabre d'Églantine, consecrated to some useful object. Thus 1 Thermidor was consecrated to spelt, 10 Thermidor to the watering-pot, 15 Thermidor to sheep, and 27 Thermidor to lentils. The most important event that took place in this month was the revolution of 9 Thermidor year II. (27th of July 1794), which resulted in the fall of Robespierre and the collapse of the Terror. The name Thermidorian (Thermidorien) was given to the authors of this revolution and to the supporters of the reactionary movement of which it was the signal.

Courtois, *Rapport fait au nom de la commission chargée de l'examen des papiers trouvés chez Robespierre et ses complices* (1795); D. A. Martin, *Papiers inédits . . . supprimés ou omis par Courtois* (3 vols., 1828); also bibliography in M. Tourneux, *Bibliog. de la ville de Paris . . .* (1890), vol. i., nos. 4265–4309.

THERMOCHEMISTRY, a branch of Energetics, treating of the thermal phenomena which are associated with chemical change.

§ 1. That vigorous chemical action is accompanied by a brisk evolution of heat is evident from such familiar examples as the combustion of fuel or the explosion of gunpowder. The heat attendant on these actions, and on the vital processes of the animal organism, naturally first attracted attention. Robert Boyle, A. Crawford, A. L. Lavoisier and P. S. Laplace, P. L. Dulong, H. Davy, Count Rumford, all concerned themselves with thermochemical investigations of such processes. Their quantitative experiments were, however, too rough to permit of accurate generalization; and although Lavoisier and Laplace stated the principle that the same amount of heat must be supplied to decompose a compound as would be produced on its formation, the statement was not based on exact experiment, and only received experimental confirmation much later.

The beginnings of modern thermochemistry, though made independently of the doctrine of the conservation of energy, are practically contemporaneous with the recognition of that law, and without it the science could scarcely have reached the degree of development which it rapidly attained. Thomas Andrews and, especially, G. H. Hess (1840) were the first who systematically investigated thermochemical effects in solution, and arrived at conclusions from their experimental data which still possess validity. Andrews, for example, found that when a series of acids were under similar conditions used to neutralize a given amount of a base, the quantity of heat evolved on the neutralization was the same in all cases. Hess, from his work, arrived at the converse conclusion, that when a series of bases were used to neutralize a given amount of an acid, the heat of neutralization was always the same. Both of these statements are correct when the powerful mineral acid and bases are considered, exceptions only arising when weak acids and bases are employed. Again, Andrews discovered that when one metal displaces another from solution of its salts (*e.g.* zinc with solutions of copper salts), the thermal effect is practically independent of the nature of the acid radical in the salt employed. Andrews likewise found that when the heat evolved on the displacement from its salts of a metal M′ by a metal M is added to the heat of displacement of another metal M″ by M′, the sum is equal to the heat which is evolved on the direct displacement of M″ from its salts by M. This affords an example of a principle which had been stated by Hess in a very general form under the name of the *Law of Constant Heat Sums*—namely, that the thermal effect of a given chemical action is the same, independently of the character and number of the stages in which it takes place. Thus, in the above example, it is immaterial whether M displaces M″ from its salt directly, or whether M first displaces M′, which is then used to displace M″. This important principle is a direct consequence of the law of the conservation of energy, but was discovered independently by Hess from accurate experiment.

Hess employed this principle to determine indirectly the *heat of formation* of compounds from their elements, when this magnitude, as is generally the case, was inaccessible to direct measurement. Thus the heat of formation of anhydrous zinc sulphate, $ZnSO_4$, which cannot be determined directly, may be arrived at by summation (in Hess's units) as follows:—

Oxidation of Zn to ZnO	5291	units
,, S to SO_3	6384	,,
Dissolution of SO_3 in much water	2566	,,
,, ZnO in the resulting aqueous H_2SO_4	1609	,,
	15850	,,
Deduct heat of dissolution of anhydrous $ZnSO_4$	1193	,,
Heat of formation of $ZnSO_4$ from Zn, S, and 4O =	14657	,,

Heats of formation are still determined for the most part in a precisely similar manner.

Hess also stated another principle on empirical grounds, which, although admitting of many exceptions, is of considerable utility and significance. It had been known long before his time that when solutions of neutral salts were mixed, and no precipitate resulted, the mixed solution was also neutral. Hess now observed that in the process of mixing such neutral solutions no thermal effect was produced—that is, neutral salts in aqueous solution could apparently interchange their radicals without evolution or absorption of heat. These experimental results were generalized by him under the title of the *Law of Thermoneutrality*.

After the investigations of Hess and Andrews, a great deal of excellent experimental work was performed by P. A. Favre and J. T. Silbermann, whose chief theoretical achievement was the recognition that the heat of neutralization of acids and bases was additively composed of two constants, one determined by the acid and the other by the base. This deduction harmonized the observations of Andrews and of Hess previously alluded to, and also accounted satisfactorily for the Law of Thermoneutrality.

Julius Thomsen was the first investigator who deliberately adopted the principle of the conservation of energy as the basis of a thermochemical system. His thermochemical work was begun in 1853, but most of his experiments were performed in the years 1869–82, the whole being published collectively, under the title *Thermochemische Untersuchungen*, in four volumes. Somewhat later than Thomsen, Marcellin P. E. Berthelot began (in 1873) a long series of thermochemical determinations. It is to these two investigators and their pupils that most of our exact thermochemical data are due.

Thomsen and Berthelot independently enunciated a generalization (commonly known as Berthelot's *Third Principle*, or *Principle of Maximum Work*), which may be stated in brief as follows:—Every pure chemical reaction is accompanied by *evolution* of heat. Whilst this principle is undoubtedly applicable to the great majority of chemical actions under ordinary conditions, it is subject to numerous exceptions, and cannot therefore be taken (as its authors originally intended) as a secure basis for theoretical reasoning on the connexion between thermal effect and chemical affinity. The existence of reactions which are reversible on slight alteration of conditions at once invalidates the principle, for if the action proceeding in one direction evolves heat, it must absorb heat when proceeding in the reverse direction. As the principle was abandoned even by its authors, it is now only of historical importance, although for many years it exerted considerable influence on thermochemical research.

§2. From the standpoint of the law of conservation of energy, the relation between chemical and thermochemical action bears the following aspect:—A given amount of any substance under given conditions possesses a perfectly definite amount of intrinsic energy, and, no matter what chemical and physical transformations the substance may undergo, it will, when it returns to its original state, possess the original amount of intrinsic energy. If we consider now the transformation of one system of chemical substances into another system under specified conditions, we shall find that in general the intrinsic energy of the second system is different from the intrinsic energy of the first. Let us assume, as is commonly the case, that the intrinsic energy of the initial system is greater than that of the final system. When the first system then is transformed into the second, the excess of energy which the former possesses must appear in the shape of heat, light, electrical energy, mechanical energy, &c. It is for the most part a simple matter to obtain the excess of energy entirely in the form of heat, the amount of which is easily susceptible of measurement, and thus the existence of thermochemistry as a practical science is rendered possible. Since the intrinsic energies of the two systems under given conditions are invariable, the difference between them is constant, so that the heat evolved when the first system is converted into the second is equal to that absorbed when the second system is re-transformed into the first (cf. Lavoisier and Laplace, *ante*, § 1). The total thermal effect, too, which is associated with the transformation, must be the same, whether the transformation is conducted directly or indirectly (Hess's *Law of Constant Heat Sums*), since the thermal effect depends only on the intrinsic energies of the initial and final systems.

Since the intrinsic energy of a substance varies with the conditions under which the substance exists, it is necessary, before proceeding to the practical application of any of the laws mentioned above, accurately to specify the conditions of the initial and final systems, or at least to secure that they shall not vary in the operations considered. It is also a necessary condition for the application of the preceding laws that no form of energy except heat and the intrinsic energy of the substances should be ultimately involved. For example, when metallic zinc is dissolved in dilute sulphuric acid with production of zinc sulphate (in solution) and hydrogen gas, a definite quantity of heat is produced for a given amount of zinc dissolved, provided that the excess of energy in the initial system appears entirely as heat. This provision may not always be fulfilled, since by placing the zinc in electrical contact with a piece of platinum, likewise immersed in the sulphuric acid, we can generate a current of electricity through the solution and the metallic part of the circuit. The reaction as before is completely expressed by the chemical equation $Zn+H_2SO_4 = ZnSO_4H+_2$, the initial and final systems being exactly the same as in the first case; yet the amount of heat generated by the action is much smaller, a quantity of the intrinsic energy having been converted into electrical energy. This electrical energy, however, is equivalent to the heat which has disappeared, for it has been shown experimentally that if it is converted into heat and added to the heat actually evolved, the total quantity of heat obtained is exactly equal to that produced by the direct dissolution of the zinc in the absence of platinum.

§ 3. The following conditions have to be considered as affecting in a greater or less degree the intrinsic energy of the initial and final systems:—

(1) Dilution of solutions.
(2) Physical state.
(3) Change of volume.
(4) Allotropic modifications.
(5) Temperature.

(1) Generally speaking, there is a considerable thermal effect when a substance is dissolved in water, and this effect varies in magnitude according to the amount of water employed. It is only, however, when we deal with comparatively concentrated solutions that the heat-effect of diluting the solutions is at all great, the heat-change on diluting an already dilute solution being for most practical purposes negligible. In dealing, therefore, with dilute solutions, it is only necessary to state that the solutions are dilute, the exact degree of dilution being unimportant. It occasionally happens that a change in dilution affects the chemical action that occurs. Thus if concentrated instead of dilute sulphuric acid acts upon zinc, the action takes place to a great extent not according to the equation given above, but according to the equation

$$Zn+2H_2SO_4 = ZnSO_4+SO_2+2H_2O,$$

sulphur dioxide and water being produced instead of hydrogen. Here we have a different final system with a different amount of intrinsic energy, so that the thermal effect of the action is altogether different.

(2) The physical state of the reacting substances must be considered, since comparatively large amounts of heat are absorbed on fusion and on vaporization. Thus the heat of fusion of ice (for $H_2O=18$ g) is 1440 cal., and the heat of vaporization of water at 100°, for the same quantity, 9670 cal.

(3) The effect of change of volume against external pressure (due to production or consumption of mechanical energy) may be neglected in the case of solids, liquids or solutions, but must usually be taken into account when gases are dealt with. Each gramme-molecule of a gas which appears under constant pressure during a chemical action (*e.g.* hydrogen during the action of zinc on dilute sulphuric acid) performs work equivalent to 580 cal. at the ordinary temperature, which must be allowed for in the thermochemical calculation. A similar correction, of opposite sign, must be made when a gramme-molecule of gas disappears during the chemical action.

(4) When a substance—*e.g.* carbon, phosphorus, sulphur—exists in allotropic forms, the particular variety employed should always be stated, as the conversion of one modification into another is frequently attended by a considerable thermal effect. Thus the conversion of yellow into red phosphorus evolves about one-sixth of the heat of combustion of the latter in oxygen, and so the knowledge of which variety of phosphorus has been employed is of essential importance in the thermochemistry of that element.

(5) The influence of temperature on the thermal effect of a chemical action is sometimes considerable, but since the initial and final temperatures, which alone determine the variation in the thermal effect, are in almost all cases within the ordinary laboratory range of a few degrees, this influence may in general be neglected without serious error.

§ 4. *Methods.*—In order to estimate the thermal effect of any chemical process, use is made of the ordinary methods of calorimetry, the particular method being selected according to the nature of the chemical action involved. In almost every case the method of mixture (see CALORIMETRY) is employed, the method of fusion with Bunsen's ice-calorimeter being only used in special and rarely occurring circumstances.

As a very great number of important chemical actions take place on mixing solutions, the method for such cases has been thoroughly studied. When the solutions employed are dilute, no water is placed in the calorimeter, the temperature-change of the solutions themselves being used to estimate the thermal effect brought about by mixing them. Known quantities of the solutions are taken, and the temperature of each is accurately measured before mixing, the solutions having been allowed as far as possible to adjust themselves to the same temperature. The change of temperature of the solutions after the mixing has taken place is then observed with the usual precautions. It is of course in such a case necessary to know the specific heat of the liquid in the calorimeter. Thomsen by direct experiment found that the heat-capacity of a dilute aqueous solution diverged in general less than 1 per cent. from the heat-capacity of the water contained in it, the divergence being sometimes in one sense, sometimes in the other. He therefore abstained from determining for each case the specific heats of the solutions he employed, and contented himself with the above approximation. Berthelot, on the other hand, assumed that the heat-capacity of an aqueous solution is equal to that of an equal volume of water, and calculated his results on this assumption, which involves much the same uncertainty as that of Thomsen. Since thermochemical measurements of this type may be frequently performed with an error due to other causes of much less than 1 per cent., the error introduced by either of these assumptions is the chief cause of uncertainty in the method.

The calorimeter used for solutions is usually cylindrical, and made of glass or a metal which is not attacked by the reacting substances. The total quantity of liquid employed need not in general exceed half a litre if a sufficiently delicate thermometer is available. The same type of calorimeter is used in determining the heat of solution of a solid or liquid in water.

Combustion calorimeters are employed for observing the heat generated by the brisk interaction of substances, one of which at least is gaseous. They are of two kinds. In the older type the combustion chamber (of metal or glass) is sunk in the calorimeter proper, tubes being provided for the entrance and exit of the gaseous substances involved in the action. These tubes are generally in the form of worms immersed in the water of the calorimeter. In the newer type (which was first proposed by Andrews for the combustion of gases) the chemical action takes place in a completely closed combustion chamber of sufficient strength to resist the pressure generated by the sudden action, which is often of explosive violence. The steel combustion chamber is of about 250 c.c. capacity, and is wholly immersed in the calorimeter. To withstand the chemical action of the gases, the "calorimetric bomb" is lined either with platinum, as in Berthelot's apparatus, or with porcelain, as in Mahler's. For ordinary combustions compressed oxygen is used, so that the combustible substance burns almost instantaneously, the action being induced by means of some electrical device which can be controlled from without the calorimeter. The accuracy of heats of combustion determined in the closed calorimeter is in favourable cases about one-half per cent. of the quantity estimated.

§ 5. *Units and Notation.*—The heat-units employed in thermochemistry have varied from time to time. The following are those which have been in most general use:—

Small calorie or gramme calorie	cal.
Large or kilogramme calorie	Cal.
Centuple or "rational" calorie	K.

The centuple calorie is the amount of heat required to raise 1 g. of water from 0° C. to 100° C., and is approximately equal to 100 cal. The large calorie is equal to 1000 cal. In view of the not very great accuracy of thermochemical measurements, the precise definition of the heat-unit employed is not a matter of special importance. It has been proposed to adopt the *joule*, with the symbol j, as thermochemical unit for small quantities of heat, large amounts being expressed in terms of the *kilojoule*, Kj = 1000 j. (For the exact relation between these heat-units, see CALORIMETRY.) For ordinary thermochemical work we may adopt the relation 1 cal. = 4·18 j, or 1 Cal. = 4·18 Kj.

Except for technological purposes, thermochemical data are not referred to unit quantity of matter, but to chemical quantities —*i.e.* to the gramme-equivalents or gramme-molecules of the reacting substances, or to some multiples of them. The notation which Julius Thomsen employed to express his thermochemical measurements is still extensively used, and is as follows:—The chemical symbols of the reacting substances are written in juxtaposition and separated by commas; the whole is then enclosed in brackets and connected by the sign of equality to the number expressing the thermal effect of the action. The chemical symbols stand for quantities measured in grammes, and heat-evolution is reckoned as positive, heat-absorption as negative. Thus

$$[S, 2O] = 71100 \text{ cal.}$$

indicates that 71100 calories are evolved when 32 grammes of sulphur react with 2×16 grammes of free oxygen to form sulphur dioxide. It is of course necessary in accurate work to state the conditions of the reaction. In the above instance the sulphur is supposed to be in the solid rhombic modification, the oxygen and sulphur dioxide being in the gaseous state, and the initial and final systems being at the ordinary temperature. Again, the equation

$$[2N, O] = -18500 \text{ cal.}$$

indicates that if 28 grammes of nitrogen could be made to unite directly with 16 grammes of oxygen to form nitrous oxide, the union would cause the absorption of 18500 calories. When substances in solution are dealt with, Thomsen indicates their state by affixing Aq to their symbols. Thus

$$[NaOH\ Aq, HNO_3\ Aq] = 13680 \text{ cal.}$$

represents the heat of neutralization of one gramme-equivalent of caustic soda with nitric acid, each in dilute aqueous solution before being brought into contact. One drawback of Thomsen's notation is that the nature of the final system is not indicated, although this defect in general causes no ambiguity.

Berthelot's notation defines both initial and final systems by giving the chemical equation for the reaction considered, the thermal effect being appended, and the state of the various substances being affixed to their formulae after brackets. W. Ostwald has proposed a modification of Berthelot's method which has many advantages, and is now commonly in use. Like Berthelot, he writes the chemical equation of the reaction, but in addition he considers the chemical formula of each substance to express not only its material composition, but also the (unknown) value of its intrinsic energy. To the right-hand member of the equation he then adds the number expressing the thermal effect of the reaction, heat-evolution being as before counted positive, and heat-absorption negative. The mass-equation then becomes an energy-equation. He thus writes

$$S + O_2 = SO_2 + 71100 \text{ cal.},$$

which expresses the fact that the intrinsic energy of the quantities of sulphur and oxygen considered exceeds that of the sulphur dioxide derived from them by 71100 cal. when thermal units are employed. The equation

$$H_2 + I_2 = 2HI - 12200 \text{ cal.}$$

expresses that under certain conditions the intrinsic energy of hydriodic acid is greater than the intrinsic energy of its component elements by 12200 cal., *i.e.* that hydriodic acid is formed from its elements with absorption of this amount of heat. Energy-equations, such as the above, may be operated with precisely as if they were algebraic equations, a property which is of great advantage in calculation. Thus by transposition we may write the last equation as follows:—

$$2HI = H_2 + I_2 + 12200 \text{ cal.},$$

and thus express that hydriodic acid when decomposed into its elements evolves 12200 cal. for the quantity indicated by the equation.

Ostwald has made the further proposal that the formulae of solids should be printed in heavy type (or within square brackets), of liquids (solutions, &c.) in ordinary type, and of gases in italics (or within curved brackets), so that the physical state of the substances might be indicated by the equation itself. Thus the equation

$$\mathit{Cl_2} + 2KI, Aq = 2KCl, Aq + \mathbf{I_2} + 52400 \text{ cal.},$$

or

$$(Cl_2) + 2KI, Aq = 2KCl, Aq + [I_2] + 52400 \text{ cal.},$$

would express that when gaseous chlorine acts on a solution of potassium iodide, with separation of solid iodine, 52400 calories are evolved.

§ 6. *Heat of Formation.*—For thermochemical calculations it is of great importance to know the heat of formation of compounds from their elements, even when the combination cannot be brought about directly. As an example of the use of Ostwald's energy-equations for the indirect determination we may take the case of carbon monoxide.

The following equations give the result of direct experiment:—

$$C + 2O = CO_2 + 94300 \text{ cal.}$$
$$CO + O = CO_2 + 68000 \text{ cal.}$$

If now it is required to find the heat of formation of the compound CO, which cannot be directly ascertained, we have merely to subtract the second equation from the first, each symbol representing constant intrinsic energy, and thus we obtain

$$C + O - CO = 26300 \text{ cal.},$$

or

$$C + O = CO + 26300 \text{ cal.},$$

that is, the heat of formation of a gramme-molecule of carbon monoxide is 26300 cal.

As has already been stated, the heat of formation of a compound is the amount (expressed in thermal units) by which its intrinsic energy exceeds or falls short of that of the elements which enter into its composition. Now of the absolute values of intrinsic energy we know nothing; we can only estimate differences of intrinsic energy when one system is compared with another into which it may be directly or indirectly converted. But since the elements cannot be converted one into the other, we are absolutely without knowledge of the relative values of their intrinsic energy. This being the case, we are at liberty to make the assumption that the intrinsic energy of each element (under specified conditions) is zero, without thereby introducing any risk of self-contradiction in thermochemical calculations. This assumption has the great advantage, that the intrinsic energy of a compound relatively to its elements now appears as the heat of formation of the compound with its sign reversed. Thus if we consider the energy-equation

$$C + O_2 = CO_2 + 94300 \text{ cal.},$$

and replace the symbols by the values of the intrinsic energy, viz. zero for carbon and oxygen, and x for carbon dioxide, we obtain the equation

$$0 + 0 = x + 94300 \text{ cal.}$$

or

$$x = -94300 \text{ cal.}$$

With knowledge then of the heats of formation of the substances involved in any chemical action, we can at once calculate the thermal effect of the action, by placing for each compound in the energy-equation its heat of formation with the sign reversed, *i.e.* its heat of decomposition into its elements. Thus if we wish to ascertain the thermal effect of the action

$$Mg + CaO = MgO + Ca,$$

we may write, knowing the heats of formation of CaO and MgO to be 131000 and 146000 respectively,

$$0 - 131000 = 0 - 146000 + x$$
$$x = 15000 \text{ cal.}$$

Since heats of formation afford such convenient data for calculation on the above method, they have been ascertained for as many compounds as possible.

Substances with positive heats of formation are termed ***exothermic;*** those with negative heats of formation are termed ***endothermic.*** The latter, which are not very numerous, give out heat on decomposition into their elements, and are more or less unstable. Amongst endothermic compounds may be noted hydriodic acid, HI, acetylene, C_2H_2, nitrous oxide, N_2O, nitric oxide, NO, azoimide, N_3H, nitrogen trichloride, NCl_3. Some of these pass into their elements with explosive violence, owing to the heat generated by their decomposition and the gaseous nature of the products.

§ 7. *Heat of Combustion.*—The thermochemical magnitude which is universally determined for organic compounds is the heat of combustion, usually by means of the calorimetric bomb. The relation between the heat of combustion of a hydrocarbon and its heat of formation may be readily seen from the following example. The hydrocarbon methane, CH_4, when completely burned to carbon dioxide and water, generates 213800 cal. We may therefore write

$$CH_4 + 4O = CO_2 + 2H_2O + 213800.$$

Now we know the heats of formation of carbon dioxide (from diamond) and of liquid water to be 94300 cal. and 68300 cal. respectively. The above equation may consequently be written, if x is the heat of formation of methane,

$$-x + 0 = -94300 - (2\times68300) + 213800$$
$$x = 17000 \text{ cal.}$$

This heat of formation, like that of most hydrocarbons, is comparatively small: the heat of formation of saturated hydrocarbons is always positive, but the heat of formation of unsaturated hydrocarbons is frequently negative. For example, ethylene, C_2H_4, is formed with absorption of 16200 cal., acetylene, C_2H_2, with absorption of 59100 cal., and liquid benzene, C_6H_6, with absorption of 9100 cal. Since the heat of combustion of a hydrocarbon is equal to the heat of combustion of the carbon and hydrogen it contains minus its heat of formation, those hydrocarbons with positive heat of formation generate less heat on burning than the elements from which they were formed, whilst those with a negative heat of formation generate more. Thus the heat generated by the combustion of acetylene, C_2H_2, is 316000 cal., whereas the heat of combustion of the carbon and hydrogen composing it is only 256900 cal., the difference being equal to the negative heat of formation of the acetylene.

For substances consisting of carbon, hydrogen and oxygen, a rule was early devised for the purpose of roughly calculating their heat of combustion (J. J. Welter's rule). The oxygen contained in the compound was deducted, together with the equivalent amount of hydrogen, and the heat of combustion of the compound was then taken to be equal to the heats of combustion of the elements in the residue. That the rule is not very accurate may be seen from the following example. Cane-sugar has the formula $C_{12}H_{22}O_{11}$. According to Welter's rule, we deduct 11 O with the equivalent amount of hydrogen, namely, 22 H, and are left with the residue 12 C, the heat of combustion of which is 1131600 cal. The observed heat of combustion of sugar is, however, 1354000, so that the error of the rule is here 20 per cent. A much better approximation to the heat of combustion of such substances is obtained by deducting the oxygen together with the amount of carbon necessary to form CO_2, and then ascertaining the amount of heat produced by the residual carbon and hydrogen. In the above case we should deduct with 11 O the equivalent amount of carbon 5·5 C, thus obtaining the residue 6·5 C and 22 H. These when burnt would yield $(6{\cdot}5\times94300)+(11\times68300)=1364250$ cal., an amount which is less than 1 per cent. different from the observed heat of combustion of sugar. Neither of the above rules can be applied to carbon compounds containing nitrogen.

§ 8. *Heat of Neutralization.*—It has already been stated that the heats of neutralization of acids and bases in aqueous solution are additively composed of two terms, one being constant for a given base, the other constant for a given acid. In addition to this, the further regularity has been observed that when the powerful monobasic acids are neutralized by the powerful monacid bases, the heat of neutralization is in all cases the same. The following table gives the heats of neutralization of the commoner strong monobasic acids with soda:—

Hydrochloric acid	HCl	137400 cal.
Hydrobromic acid	HBr	137500 „
Hydriodic acid	HI	136800 „
Nitric acid	HNO_3	136800 „
Chloric acid	$HClO_3$	137600 „
Bromic acid	$HBrO_3$	137800 „

Within the error of experiment these numbers are identical.

It was at one time thought that the greater the heat of neutralization of an acid with a given base, the greater was the strength of the acid. It is now known, however, that when weak acids or bases are used, the heat of neutralization may be either greater or less than the normal value for powerful acids and bases, so that there is no proportionality, or even parallelism, between the strengths of acids and their heats of neutralization (see SOLUTIONS).

§ 9. *Heat of Solution.*—When substances readily combine with water to form hydrates, the heat of solution in water is usually positive; when, on the other hand, they do not readily form hydrates, or when they are already hydrated, the heat of solution is usually negative. The following examples show the effect of hydration on heat of solution in a large quantity of water:—

	Heat of Solution.	Heat of Hydration.
I. Sodium carbonate—		
Na_2CO_3	+5640 cal.	
Na_2CO_3, H_2O	+2250 „	+3390 cal.
Na_2CO_3, $2H_2O$	+20 „	+5620 „
Na_2CO_3, $10H_2O$	−16160 „	+21800 „
II. Sodium sulphate—		
Na_2SO_4	+460 cal.	
Na_2SO_4, H_2O	−1900 „	+2360 cal.
Na_2SO_4, $10H_2O$	−18760 „	+19200 „

§ 10. *Application of the Second Law of Thermodynamics to Thermochemistry.*—What is commonly understood by thermochemistry is based entirely on the first law of thermodynamics, but of recent years great progress has been made in the study of chemical equilibrium by the application of the second law. For an account of work in this direction see CHEMICAL ACTION.

THERMODYNAMICS (from Gr. θερμός, hot, δύναμις, force). 1. The name thermodynamics is given to that branch of the general science of Energetics which deals with the relations between thermal and mechanical energy, and the transformations of heat into work, and vice versa. Other transformations of heat are often included under the same title (see ENERGETICS). An historical account of the development of thermodynamics is given in the article HEAT. The object of the present article is to illustrate the practical application of the two general principles— (1) Joule's law of the equivalence of heat and work, and (2) Carnot's principle, that the efficiency of a reversible engine depends only on the temperatures between which it works; these principles are commonly known as the first and second laws of thermodynamics. The application will necessarily be confined to simple cases such as are commonly met with in practice, or are required for reference in cognate subjects.

2. *Application of the First Law.*—The complete transformation of mechanical energy into heat by friction, or some analogous process of degradation, is always possible, and is made the basis of experiments for the determination of the mechanical equivalent of the heat unit (see CALORIMETRY). The converse process of the transformation of heat into mechanical work or other forms of energy is subject to limitations.

When a quantity of heat, H, is supplied to a body, part is expended in raising the temperature of the body, or in expanding the volume against molecular forces, and is represented by an increase in the total quantity of energy contained in the body, which is generally called its *Intrinsic Energy*, and will be denoted by the symbol E. The remainder is equivalent to the external work, W, done *by* the body in expanding or otherwise, which can be utilized for mechanical purposes, and ceases to exist as heat in the body. The application of the first law leads immediately to the equation,

$$H=E-E_0+W, \qquad (1)$$

in which E_0 represents the quantity of energy originally present in the body, and all the quantities are supposed, as usual, to be expressed in mechanical units. This equation is generally true for any series of transformations, provided that we regard H and W as representing the *algebraic sums* of all the quantities of heat supplied to, and of work done *by* the body, heat taken *from* the body or work done *on* the body being reckoned negative in the summation. $E-E_0$, then, represents the total increase of the intrinsic energy of the body in its final state, which may be determined by measuring H and W. If after any series or cycle of transformations the body is restored to its initial state, we must have $E=E_0$, whence it follows that $H=W$. But this simple relation is only true of the net balances of heat and work in a complete cyclical process, which must be adopted for theoretical purposes if we wish to eliminate the unknown changes of intrinsic energy. The balance of work obtainable in such a cycle depends on the limits of temperature in a manner which forms the subject of the second law.

3. *Indicator or p.v. Diagram.*—The significance of relation (1) is best appreciated by considering the graphic representation of quantities of heat and energy on a work-diagram.

On the familiar indicator diagram the state of the working substance is represented by the position of a point called the "state-point," defined by the values of the pressure p and volume v of *unit mass*, as ordinate and abscissa respectively (fig. 1). Any line ("path" or "graph") on the diagram, such as BCD, represents an "operation" or "process" *i.e.* a continuous series of states through which the substance may be made to pass in any transformation. It is tacitly assumed that the motion is relatively so slow that the pressure and temperature of the substance are practically uniform throughout its mass at any stage of the process. Otherwise the transformation could not be fully represented on the diagram, and would not be reversible. The area BCD*db* under the path represents the external work done *by* the substance in expanding from B to D, which is analytically represented by the integral of pdv taken along the given path. Any closed path or figure, such as ABCD, represents a complete cycle or series of operations, in the course of which the substance is restored to its original state with respect to temperature, intrinsic energy and other properties. The area DABbd under the return path (v diminishing) represents work done *on* the substance, or against the back-pressure, and is negative. The area of the cycle, viz., that enclosed by the path BCDA, represents the balance of external work done by the substance in one cycle, and is positive if the cycle is described clockwise as indicated by the arrows. The simplest types of process or operation are:—(1), heating or cooling *at constant volume*, represented by vertical lines such as Bb, called *Isometrics*, in which the pressure varies, but no external work is done. (2) Heating or cooling *at constant pressure*, represented by horizontal lines such as NA, called *Isopiestics*, in which the external work done is the product of the pressure p and the expansion $v''-v'$. (3) Expansion or compression *at constant temperature*, represented by curves called *Isothermals*, such as BC, AD, the form of which depends on the nature of the working substance. The isothermals are approximately equilateral hyperbolas (pv=constant), with the axes of p and v for asymptotes, for a gas or unsaturated vapour, but coincide with the isopiestics for a saturated vapour in presence of its liquid. (4) Expansion or compression under the condition of *heat-insulation*, represented by curves called *Adiabatics*, such as BAZ or CDZ′, which are necessarily steeper than the isothermals.

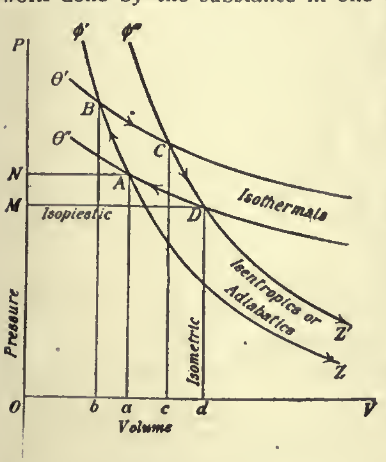

FIG. 1.

A cycle such as ABCD enclosed by parts of two isothermals, BC, AD, and two adiabatics, AB, CD, is the simplest form of cycle for theoretical purposes, since all the heat absorbed, H', is taken in during the process represented by one isothermal at the temperature θ', and all the heat rejected, H'', is given out during the process represented by the other at the temperature θ''. This is the cycle employed by Carnot for the establishment of his fundamental principle of reversibility as the criterion of perfect efficiency in a heat engine. The area ABCD, representing the work, W, per cycle, is the difference $(H'-H'')$ of the quantities of heat absorbed and rejected at the temperatures θ' and θ''. As the temperature θ'' is lowered, the area of the cycle increases, but since W can never exceed H', there must be a zero limit of temperature at which the pressure would vanish and the area of the cycle become equal to the whole heat absorbed at the higher temperature. Taking this ideal limit as a theoretical or absolute zero, the value of H' may be represented on the diagram by the whole area included between the two adiabatics BAZ, CDZ′ down to the points where they intersect the isothermal of absolute zero, or the zero isopiestic OV asymptotically at infinity.

If the substance in any state such as B were allowed to expand adiabatically ($dH=0$) down to the absolute zero, at which point it contains no heat and exerts no pressure, the whole of its available heat energy might theoretically be recovered in the form of external work, represented on the diagram by the whole area BAZcb under the adiabatic through the state-point B, bounded by the isometric Bb and the zero isopiestic bV. The change of the intrinsic energy in passing from one state to another, as from B to C is represented by the addition of the heat-area H=BCZZ′, and the subtraction of the work-area W=BCcb. It follows from the first law that the intrinsic energy of a substance in a given state must always be the same, or that the change of E in any transformation must depend only on the initial and final states, and not on the path or process. It will be observed that the areas representing H and W both depend on the form of the path BC, but that the difference of the areas representing the change of intrinsic energy dE is independent of BC, which is a boundary common to both H and W. This is mathematically expressed by the statement that dE is an exact differential of a function of the co-ordinates defining the state of the body, which can be integrated between limits without reference to the relation representing the path along which the variations are taken.

4. *Application of Carnot's Principle.*—Carnot adopted as the analytical expression of his principle the statement that the efficiency W/H, or the work obtainable per unit of heat by means of a perfect engine taking in heat at a temperature $t°$ C. and rejecting heat at 0° C., must be some function $F(t)$ of the temperature t, the lower limit 0° C. being supposed constant. He was unable to apply the principle directly in this form, as it would require an exact knowledge of the properties of substances through a wide range of temperature. He therefore employed the corresponding expression for a cycle of infinitesimal range dt at the temperature t in which the work dW obtainable from a quantity of heat H would be represented by the equation

$$dW=HF'(t)dt,$$

where $F'(t)$ is the derived function of $F(t)$, or $dF(t)/dt$, and represents the work obtainable per unit of heat per degree fall of temperature at a temperature t. The principle in this form is readily applicable to all cases, and is independent of any view with regard to the nature of the heat. It simply asserts that the efficiency function $F'(t)$, which is known as Carnot's function, is the same for all substances at the same temperature. Carnot verified this by calculating the values of $F'(t)$ at various temperatures from the known properties of vapours and gases, and showed that the efficiency function diminished with rise of temperature, as measured on the scale of the mercury or gas thermometer, from about 1·40 kilogrammetres per kilo-calorie per degree C. at 0° C. to about 1·11 at 100° C., according to the imperfect data available in his time. Applying the above equation to a gas obeying the law $pv=RT$, for which the work done in isothermal expansion from a volume 1 to a volume r is $W=RT\log_e r$, whence $dW=R\log_e r dt$, he deduced the expression for the heat absorbed by a gas in isothermal expansion

$$H=R\log_e r/F'(t).$$

He also showed that the difference of the specific heats at constant pressure and volume, $S-s$, must be the same for equal volumes of all gases at the same temperature and pressure, being represented by the expression $R/TF'(t)$. He remarks that "the law according to which the motive power of heat varies at different points of the thermometric scale is intimately connected with that of the variations of the specific heats of gases at different temperatures—a law which experiment has not yet made known to us with sufficient exactness." If he had ventured to assume the difference of the specific heats constant, it would have followed that $F'(t)$ must vary inversely as T. The same result follows if the work $W=RT\log_e r$ done by a gas in isothermal expansion is assumed to be equivalent or proportional to the heat absorbed, $H=R\log_e r/F'(t)$. Mayer (1842) made this assumption in calculating the mechanical equivalent of heat. Joule (1845) was the first to prove it approximately by direct experiment, but did not see his way to reconcile Carnot's principle, as stated by Clapeyron, with the mechanical theory. Holtzmann (1845) by the same assumption deduced the value J/T for the function $F'(t)$, but obtained erroneous results by combining this assumption with the caloric theory. Clausius (1850), applying the same assumption, deduced the same value of $F'(t)$, and showed that it was consistent with the mechanical theory and Joule's experiments, but required that a vapour like steam should deviate more considerably from the gaseous laws than was at that time generally admitted. The values of $F'(t)$ calculated previously by Sir W. Thomson (Lord Kelvin) from Regnault's tables of the properties of steam, assuming the gaseous laws, did not vary exactly as J/T. Joule's experiments on the equivalence of W and H were not sufficiently precise to decide the question. This most fundamental point was finally settled by a more delicate test, devised by Lord Kelvin, and carried out in conjunction with Joule (1854), which showed that the fundamental assumption $W=H$ in isothermal expansion was very nearly true for permanent gases, and that $F'(t)$ must therefore vary very nearly as J/T. Kelvin had previously proposed to define an absolute scale of temperature independent of the properties of any particular substance in terms of Carnot's function by making $F'(t)$ constant. He now proposed to define absolute temperature as proportional to the reciprocal of Carnot's function, so as to agree as closely as possible with the scale of the gas thermometer. With this definition of temperature θ, if the heat H is measured in work units, the expression of Carnot's principle for an infinitesimal cycle of range $d\theta$ reduces to the simple form $dW/d\theta=H/\theta$. Combining this with the first law, for a Carnot cycle of finite range, if H' is the heat taken in at θ', and H'' is the heat rejected at θ'', the work W done in the cycle is equal to the difference $H'-H''$, and we have the simple relations,

$$W/(\theta'-\theta'')=H'/\theta'=H''\theta'' \quad . \quad . \quad . \quad (2)$$

5. *Thermodynamical Relations.*—The most important and most useful of the relations between the thermodynamical properties of a substance may be very simply deduced from a consideration of the indicator diagram by a geometrical method, which is in many respects more instructive than the analytical method generally employed. Referring to fig. 2, let BC be a small portion of any isothermal corresponding to the temperature θ', and AD a neighbouring isothermal θ''. Let BE be an isometric through B meeting AD in E, and EC an isopiestic through E meeting BC in C. Let BA, CD be adiabatics through B and C meeting the isothermal θ'' in A and D. Then by relations (2) the heat, H, absorbed in the isothermal change BC, is to the work, W, done in the cycle ABCD in the ratio of θ' to $(\theta'-\theta'')$. If the difference

of temperature $(\theta'-\theta'')$ is small, the figure ABCD may be regarded as a parallelogram, and its area W as equal to the rectangle BE×EC. This is accurately true in the limit when $(\theta'-\theta'')$ is infinitesimal, but in practice it is necessary to measure specific heats, &c., over finite ranges of temperature, and the error involved is generally negligible if the range does not exceed a few degrees. BE is the increase of pressure $(p'-p'')$ produced by the rise of temperature $(\theta'-\theta'')$ if the volume is kept constant. EC is the expansion $(v''-v')$ produced by the same rise of temperature if the pressure is kept constant. Substituting these symbols in the expression for the area, the relation becomes

$$H=\theta(p'-p'')(v''-v')/(\theta'-\theta'') \quad . \quad . \quad . \quad (3)$$

This relation may be interpreted in two ways, according as we require the heat absorbed in terms of the change of pressure or volume. (1) The heat, H, absorbed in isothermal expansion (latent heat of expansion) from p' to p'' is equal to the diminution of pressure $(p'-p'')$ multiplied by the absolute temperature and by the expansion per degree $(v''-v')/(\theta'-\theta'')$ at constant pressure. (2) The heat, H, absorbed in isothermal expansion from v' to v'' is equal to the increase of volume $(v''-v')$ multiplied by the absolute temperature, and by the increase of pressure per degree $(p'-p'')/(\theta'-\theta'')$, at constant volume. In the notation of the calculus the relations become

$$\left.\begin{aligned} -dH/dp\ (\theta \text{ const}) &= \theta dv/d\theta\ (p \text{ const}) \\ dH/dv\ (\theta \text{ const}) &= \theta dp/d\theta\ (v \text{ const}) \end{aligned}\right\} \quad . \quad . \quad . \quad (4)$$

The negative sign is prefixed to dH/dp because absorption of heat $+dH$ corresponds to diminution of pressure $-dp$. The utility of these relations results from the circumstance that the pressure and expansion coefficients are familiar and easily measured, whereas the latent heat of expansion is difficult to determine.

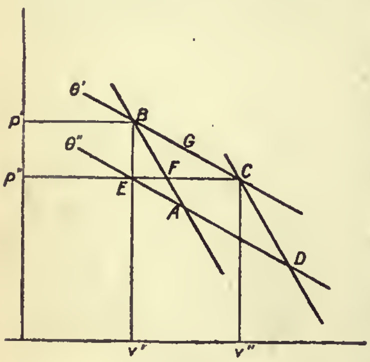

FIG. 2.

The most instructive example of the application of relations (1) and (2) is afforded by the change of state of a substance at constant temperature and pressure. Starting with unit mass of the substance in the first state (*e.g.* liquid) possessing volume v' at a temperature θ'' and pressure p'' represented by the point A in fig. 3, the heat absorbed in raising the temperature to θ' and the pressure to p' without change of state may be written $s'(\theta'-\theta'')$, where s' is the specific heat of the substance in the first state at saturation pressure. If now the substance in the state B is entirely converted at constant temperature and pressure into the second state (*e.g.* saturated vapour), in which it occupies a volume v'', the line BC represents the change of volume $(v''-v')$. The heat absorbed in this change is called the latent heat of change of state, and may be represented by the symbol L'. The substance is then cooled to the lower temperature θ'' along the path CD, keeping it in the saturated state. The heat evolved in this process may be represented by $s''(\theta'-\theta'')$, where s'' is the specific heat of the substance in the second state at saturation pressure. Finally, the substance is reconverted into the first state at the temperature θ'', completing the cycle by the abstraction of a quantity of heat L''. By the application of the first law, the difference of the quantities of heat absorbed and evolved in the cycle must be equal to the work represented by the area of the cycle, which is equal to $(p'-p'')(v''-v')$ in the limit when the difference of pressure is small. By the application of the second law, relations (2), the same work area is equal to $(\theta'-\theta'')L'/\theta'$. Dividing by $(\theta'-\theta'')$, and writing $dp/d\theta$ and $dL/d\theta$ for the limiting values of the ratios $(p'-p'')/(\theta'-\theta'')$ and $(L'-L'')/(\theta'-\theta'')$, we obtain the important relations

$$s'-s''+dL/d\theta=(v''-v')dp/d\theta=L/\theta, \quad . \quad . \quad . \quad (5)$$

in which $dp/d\theta$ is the rate of change of pressure with temperature when the two states are in equilibrium. It is not necessary in this example that AB, CD should be adiabatics, because the change of volume BC is finite. The same equations apply to the case of fusion of a solid, if L is the latest heat of fusion, and v', s', v'', s'' the specific volumes and specific heats of the solid and liquid respectively.

6. *Ratio and Difference of Specific Heats.*—If we take unit mass of the substance at B, fig. 2, and cool it at constant volume to E, through an interval of temperature $(\theta'-\theta'')$, the amount of heat abstracted may be written $h=s(\theta'-\theta'')$, where s is the specific heat *at constant volume.* If, starting from E, *the same* amount of heat h is restored *at constant pressure*, we should arrive at the point F on the adiabatic through B, since the substance has been transformed from B to F by a reversible path without loss or gain of heat on the whole. In order to restore the substance to its original temperature θ' *at constant pressure*, it would be necessary to supply a further quantity of heat, H, represented by the area between the two adiabatics from FC down to the absolute zero. This quantity of heat is the same as that already found in equation (3), but for the small area BFC, which is negligibly small in the limit compared with H. The whole quantity of heat required to raise the temperature from θ'' to θ' at constant pressure along the path EC is $H+h$, which is equal to $S(\theta'-\theta'')$, where S is the specific heat at constant pressure. Since $h=s(\theta'-\theta'')$, the difference $S-s$ between the specific heats at constant pressure and volume is evidently $H/(\theta'-\theta'')$. Substituting for H its value from (3), and employing the notation of the calculus, we obtain the relation

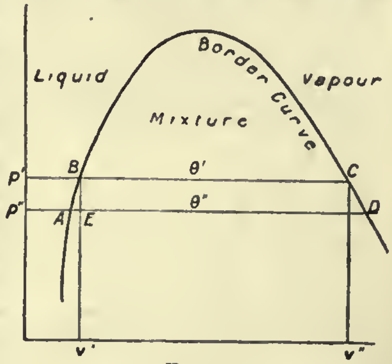

FIG. 3.

$$S-s=\theta(dp/d\theta)(dv/d\theta), \quad . \quad . \quad . \quad . \quad (6)$$

in which the partial differential coefficients have the same meaning as in (4).

Since the amounts of heat supplied at constant pressure from E to F and from E to C are in the limit proportional to the expansions EF and EC which they produce, the ratio S/s is equal to the ratio EC/EF. EF is the change of volume corresponding to a change of pressure BE when no heat is allowed to escape and the path is the adiabatic BF. EC is the change of volume for *the same* change of pressure BE when the path is the isothermal BC. These changes of volume are directly as the compressibilities, or inversely as the elasticities. If we write K for the adiabatic elasticity, and k for the isothermal elasticity, we obtain

$$S/s=\text{EC/EF}=K/k \quad . \quad . \quad . \quad . \quad (7)$$

The value of the specific heat S at constant pressure can always be determined by experiment, and in practice is one of the most important thermodynamical properties of a substance. The value of the specific heat s at constant volume can also be measured in a few cases, but it is generally necessary to deduce it from that at constant pressure by means of relation (6). It is often impossible to observe the pressure-coefficient $dp/d\theta$ directly, but it may be deduced from the isothermal compressibility by means of the geometrically obvious relation, BE=(BE/EC)×EC. The ratio BE/EC of the diminution of pressure to the increase of volume at constant temperature, or $-dp/dv$, is readily observed.

The amount of heat absorbed in any small change of state, as from E to G in fig. 2, may be found by adding to the heat required for the change of temperature at constant volume, $sd\theta$, or at constant pressure, $Sd\theta$, the heat absorbed in isothermal expansion as given by relations (4). We thus obtain the expressions

$$dH=sd\theta+\theta(dp/d\theta)dv=Sd\theta-\theta(dv/d\theta)dp \quad . \quad . \quad . \quad (8)$$

The first is equivalent to measuring the heat along the path EBG, the second along the path ECG. The two differ by the area BEC, which can be neglected if the change is small. For a finite change it is necessary to represent the path by a series of small steps, which is the graphic equivalent of integration along the path represented by the given relation between v and θ, or p and θ. If we put $dH=0$ in equations (8), we obtain the relations between dv and $d\theta$, or dp and $d\theta$, under the condition of no heat-supply, *i.e.* along the adiabatic, which can be integrated, giving the equations to the adiabatics, provided that the values of the specific heats and expansion-coefficients are known.

6. *Intrinsic Energy.*—The change of intrinsic energy E along any path is found by subtracting the work pdv from either of the expressions for dH. Since the change of energy is independent of the path, the finite change between any two given states may be found by integration along *any* convenient path. It is generally convenient to divide the path into two steps, isothermal and isometric, or isothermal and isopiestic, and to integrate along each separately. The change of energy at constant volume is simply $sd\theta$, the change at constant temperature is $(\theta dp/d\theta-p)dv$, which may be written

$$dE/d\theta\ (v \text{ const})=s,\ dE/dv\ (\theta \text{ const})=\theta dp/d\theta-p \quad . \quad (9)$$

These must be expressed as functions of v and θ, which is theoretically possible if the values of s, p, and $dp/d\theta$ are known. Since the two expressions (9) are the partial differential-coefficients of a single function E of the independent variables v and θ, we shall obtain the same result, namely $d^2E/d\theta dv$, if we differentiate the first with respect to v and the second with respect to θ. We thus obtain the relation

$$ds/dv(\theta \text{ const})=\theta d^2p/d\theta^2\ (v \text{ const}), \quad . \quad . \quad . \quad (10)$$

which is useful for calculating the variation of the specific heat s with variation of density at constant temperature. A similar expression for the variation of the specific heat S at constant pressure is obtained from the second expression in (8), by taking p and θ as independent variables; but it follows more directly from a consideration of the variation of the function $(E+pv)$.

7. *Total Heat.*—The function $F=(E+pv)$, like E itself, has a value depending only on the state of the body. It may conveniently be called the *Total Heat*, by a slight extension of the meaning of a term which has been for a long time in use as applied to vapours (see VAPORIZATION). Since $dE=dH-pdv$, we have evidently for the variation of the total heat from the second expression (8),

$$dF=d(E+pv)=dH+vdp=Sd\theta-(\theta dv/d\theta-v)dp \quad . \quad (11)$$

This expression shows that the rate of variation of the total heat with temperature at constant pressure is equal to the specific heat at constant pressure. To find the total heat of a substance in any given state defined by the values of p and θ, starting from any convenient zero of temperature, it is sufficient to measure the total heat required to raise the substance to the final temperature under a constant pressure equal to p. For instance, in the boiler of a steam engine the feed water is pumped into the boiler against the final pressure of the steam, and is heated under this constant pressure up to the temperature of the steam. The total heat with which we are actually concerned in the working of a steam engine is the total heat as here defined, and not the total heat as defined by Regnault, which, however, differs from $(E+pv)$ only by a quantity which is inappreciable in ordinary practice.

Observing that F is a function of the co-ordinates expressing the state of the substance, we obtain for the variation of S with pressure at constant temperature,

$$dS/dp\ (\theta \text{ const})=d^2F/d\theta dp=-\theta d^2v/d\theta^2\ (p \text{ const}) \quad . \quad (12)$$

If the heat supplied to a substance which is expanding reversibly and doing external work, pdv, is equal to the external work done, the intrinsic energy, E, remains constant. The lines of constant energy on the diagram are called *Isenergics*. The equation to these lines in terms of v and θ is obtained by integrating

$$dE=sd\theta+(\theta dp/d\theta-p)dv=0 \quad . \quad . \quad . \quad (13)$$

If, on the other hand, the heat supplied is equal to $-vdp$, we see from (11) that F remains constant. The equation to the lines of constant total heat is found in terms of p and θ by putting $dF=0$ and integrating (11).

8. *Ideal Gases.*—An ideal gas is a substance possessing very simple thermodynamic properties to which actual gases and vapours appear to approximate indefinitely at low pressures and high temperatures. It has the characteristic equation $pv=R\theta$, and obeys Boyle's law at all temperatures. The coefficient of expansion at constant pressure is equal to the coefficient of increase of pressure at constant volume. The difference of the specific heats by equation (6) is constant and equal to R. The isothermal elasticity $-v(dp/dv)$ is equal to the pressure p. The adiabatic elasticity is equal to γp, where γ is the ratio S/s of the specific heats. The heat absorbed in isothermal expansion from v_0 to v at a temperature θ is equal to the work done by equation (8) (since $d\theta=0$, and $\theta(dp/d\theta)dv=pdv$), and both are given by the expression $R\theta \log_e(v/v_0)$. The energy E and the total heat F are functions of the temperature only, by equations (9) and (11), and their variations take the form $dE=sd\theta$, $dF=Sd\theta$. The specific heats are independent of the pressure or density by equations (10) and (12). If we also assume that they are constant with respect to temperature (which does not necessarily follow from the characteristic equation, but is generally assumed, and appears from Regnault's experiments to be approximately the case for simple gases), the expressions for the change of energy or total heat from θ_0 to θ may be written $E-E_0=s(\theta-\theta_0)$, $F-F_0=S(\theta-\theta_0)$. In this case the ratio of the specific heats is constant as well as the difference, and the adiabatic equation takes the simple form, $pv^\gamma=$ constant, which is at once obtained by integrating the equation for the adiabatic elasticity, $-v(dp/dv)=\gamma p$.

The specific heats may be any function of the temperature consistently with the characteristic equation provided that their difference is constant. If we assume that s is a linear function of θ, $s=s_0(1+a\theta)$, the adiabatic equation takes the form,

$$s_0 \log^e(\theta/\theta_0)+as_0(\theta-\theta_0)+R\log_e(v/v_0)=0 \quad . \quad . \quad . \quad (14)$$

where (θ_0,v), (θ_0,v_0) are any two points on the adiabatic. The corresponding expressions for the change of energy or total heat are obtained by adding the term $\frac{1}{2}as_0(\theta^2-\theta_0^2)$ to those already given, thus:

$$E-E_0=s_0(\theta-\theta_0)+\tfrac{1}{2}as_0(\theta^2-\theta_0^2),$$
$$F-F_0=S_0(\theta-\theta_0)+\tfrac{1}{2}as_0(\theta^2-\theta_0^2),$$

where $S_0=s_0+R$.

9. *Deviations of Actual Gases from the Ideal State.*—Since no gas is ideally perfect, it is most important for practical purposes to discuss the deviations of actual gases from the ideal state, and to consider how their properties may be thermodynamically explained and defined. The most natural method of procedure is to observe the deviations from Boyle's law by measuring the changes of pv at various constant temperatures. It is found by experiment that the change of pv with pressure at moderate pressures is nearly proportional to the change of p, in other words that the coefficient $d(pv)/dp$ is to a first approximation a function of the temperature only. This coefficient is sometimes called the "angular coefficient," and may be regarded as a measure of the deviations from Boyle's law, which may be most simply expressed at moderate pressures by formulating the variation of the angular coefficient with temperature. But this procedure in itself is not sufficient, because, although it would be highly probable that a gas obeying Boyle's law at all temperatures was practically an ideal gas, it is evident that Boyle's law would be satisfied by any substance having the characteristic equation $pv=f(\theta)$, where $f(\theta)$ is any arbitrary function of θ, and that the scale of temperatures given by such a substance would not necessarily coincide with the absolute scale. A sufficient test, in addition to Boyle's law, is the condition $dE/dv=0$ at constant temperature. This gives by equation (9) the condition $\theta dp/d\theta=p$, which is satisfied by any substance possessing the characteristic equation $p/\theta=f(v)$, where $f(v)$ is any arbitrary function of v. This test was applied by Joule in the well-known experiment in which he allowed a gas to expand from one vessel to another in a calorimeter without doing external work. Under this condition the increase of intrinsic energy would be equal to the heat absorbed, and would be indicated by fall of temperature of the calorimeter. Joule failed to observe any change of temperature in his apparatus, and was therefore justified in assuming that the increase of intrinsic energy of a gas in isothermal expansion was very small, and that the absorption of heat observed in a similar experiment in which the gas was allowed to do external work by expanding against the atmospheric pressure was equivalent to the external work done. But owing to the large thermal capacity of his calorimeter, the test, though sufficient for his immediate purpose, was not delicate enough to detect and measure the small deviations which actually exist.

10. *Method of Joule and Thomson.*—William Thomson (Lord Kelvin), who was the first to realize the importance of the absolute scale in thermodynamics, and the inadequacy of the test afforded by Boyle's law or by experiments on the constancy of the specific heat of gases, devised a more delicate and practical test, which he carried out successfully in conjunction with Joule. A continuous stream of gas, supplied at a constant pressure and temperature, is forced through a porous plug, from which it issues at a lower pressure through an orifice carefully surrounded with non-conducting material, where its temperature is measured. If we consider any short length of the stream bounded by two imaginary cross-sections A and B on either side of the plug, unit mass of the fluid in passing A has work, $p'v'$, done on it by the fluid behind and carries its energy, $E'+U'$, with it into the space AB, where U' is the kinetic energy of flow. In passing B it does work, $p''v''$, on the fluid in front, and carries its energy, $E''+U''$, with it out of the space AB. If there is no external loss or gain of heat through the walls of the pipe, and if the flow is steady, so that energy is not accumulating in the space AB, we must evidently have the condition $E'+U'+p'v'=E''+U''+p''v''$ at any two cross-sections of the stream. It is easy to arrange the experiment so that U is small and nearly constant. In this case the condition of flow is simply that of constant total heat, or in symbols, $d(E+pv)=0$. We have therefore, by equation, (11),

$$Sd\theta=(\theta dv/d\theta-v)dp, \quad . \quad . \quad . \quad . \quad (15)$$

where $d\theta$ is the fall of temperature of the fluid corresponding to a diminution of pressure dp. If there is no fall of temperature in passing the plug, $d\theta=0$, and we have the condition $\theta dv/d\theta=v$. The characteristic equation of the fluid must then be of the form $v/\theta=f(p)$, where $f(p)$ is any arbitrary function of p. If the fluid is a gas also obeying Boyle's law, $pv=f(\theta)$, then it must be an ideal gas. As the result of their experiments on actual gases (air, hydrogen, and CO_2), Joule and Thomson (*Phil. Trans.*, 1854, 1862) found that the cooling effect, $d\theta$, was of the same order of magnitude as the deviations from Boyle's law in each case, and that it was proportional to the difference of pressure, dp, so that $d\theta/dp$ was nearly constant for each gas over a range of pressure of five or six atmospheres. By experiments at different temperatures between 0° and 100° C., they found that the cooling effect per atmosphere of pressure varied inversely as the square of the absolute temperature for air and CO_2. Putting $d\theta/dp=A/\theta^2$ in equation (15), and integrating on the assumption that the small variations of S could be neglected over the range of the experiment, they found a solution of the type, $v/\theta=f(p)-SA/3\theta^3$, in which $f(p)$ is an arbitrary function of p. Assuming that the gas should approximate indefinitely to the ideal state $pv=R\theta$ at high temperatures, they put $f(p)=R/p$, which gives a characteristic equation of the form

$$v=R\theta/p-SA/3\theta^2 \quad . \quad . \quad . \quad . \quad . \quad (16)$$

An equation of a similar form had previously been employed by Rankine (*Trans. Roy. Soc. Ed.*, 1854) to represent Regnault's experiments on the deviations of CO_2 from Boyle's law. This equation is practically identical for moderate pressures with that devised by Clausius (*Phil. Mag.*, 1880) to represent the behaviour of CO_2 up to the critical point. Experiments by Natanson on CO_2 at 17° C. confirm those of Joule and Thomson, but show a slight increase of the ratio $d\theta/dp$ at higher pressures, which is otherwise rendered probable by the form of the isothermals as determined by Andrews and Amagat. More recent experiments by J. H. Grindley (*Proc. Roy. Soc.*, 1900, 66, p. 79) and Callendar (*Proc. Roy. Soc.*, 1900) on steam confirm this type of equation, but give much larger values of the cooling effect than for CO_2, and a more rapid rate of variation with temperature.

11. *Modified Joule-Thomson Equation.*—G. A. Hirn (*Théorie Mec. de la Chaleur*, ii. p. 211, Paris, 1869) proposed an equation of the form $(p+p_0)(v-b)=R\theta$, in which the effect of the size of the molecules is represented by subtracting a quantity b, the "co-volume," from the volume occupied by the gas, and the effect of the mutual attractions of the molecules is represented by adding a quantity p_0, the internal pressure, to the external pressure, p. This type of equation, was more fully worked out by van der Waals, who identified the internal pressure, p_0, with the capillary pressure of Laplace, and assumed that it varied directly as the square of the density, and could be written a/v^2. This assumption represents qualitatively the theoretical isothermal of James Thomson (see VAPORIZATION) and the phenomena of the critical state (see CONDENSATION OF GASES); but the numerical results to which it leads differ so widely from experiment that it is necessary to suppose the constant, a, to be a function of the temperature. Many complicated expressions have been suggested by subsequent writers in the attempt to represent the continuity of the gaseous and liquid states in a single formula, but these are of a highly empirical nature, and beyond the scope of the present inquiry. The simplest assumption which suffices to express the small deviations of gases and vapours from the ideal state *at moderate pressures* is that the coefficient a in the expression for the capillary pressure varies inversely as some power of the absolute temperature. Neglecting small terms of the second order, the equation may then be written in the form

$$v-b=R\theta/p-c_0(\theta_0/\theta)^n=V-c, \quad . \quad . \quad . \quad (17)$$

in which c is a small quantity (expressing the defect from the ideal volume $V=R\theta/p$ due to co-aggregation of the molecules) which varies inversely as the nth power of θ, but is independent of p to a first approximation at moderate pressures. The constant c_0 is the value of c at some standard temperature θ_0. The value of the index, n, appears to be different for different types of molecule. For CO_2 at ordinary temperatures $n=2$, as in the Joule-Thomson equation. For steam between 100° and 150° C. it approaches the value 3·5. It is probably less than 2 for air and the more perfect gases. The introduction of the covolume, b, into the equation is required in order to enable it to represent the behaviour of hydrogen and other gases at high temperatures and pressures according to the experiments of Amagat. It is generally taken as constant, but its value at moderate pressures is difficult to determine. According to van der Waals, assuming spherical molecules, it should be four times; according to O. E. Meyer, on slightly different assumptions, it should be $4\sqrt{2}$ times, the actual volume of the molecules. It appears to be a quantity of the same order as the volume of the liquid, or as the limiting volume of the gas at very high pressures. The value of the co-aggregation volume, c, at any temperature, assuming equation (17), may be found by observing the deviations from Boyle's law and by experiments on the Joule-Thomson effect. The value of the angular coefficient $d(pv)/dp$ is evidently $(b-c)$, which expresses the defect of the actual volume v from the ideal volume $R\theta/p$. Differentiating equation (17) at constant pressure to find $dv/d\theta$, and observing that $dc/d\theta=-nc/\theta$, we find by substitution in (15) the following simple expression for the cooling effect $d\theta/dp$ in terms of c and b,

$$S d\theta/dp=(n+1)c-b \quad . \quad . \quad . \quad . \quad (18)$$

Experiments at two temperatures suffice to determine both c and n if we assume that b is equal to the volume of the liquid. But it is better to apply the Boyle's law test in addition, provided that errors due to surface condensation can be avoided. The advantage of this type of equation is that c is a function of the temperature only. Other favourite types of equation for approximate work are (1) $p=R\theta/v+f(v)$, which makes p a linear function of θ at constant volume, as in van der Waal's equation; (2) $v=R\theta/p+f(p)$, which makes v a linear function of θ at constant pressure. These have often been employed as empirical formulae (*e.g.* Zeuner's formula for steam), but they cannot be made to represent with sufficient approximation the deviations from the ideal state at moderate pressures and generally lead to erroneous results. In the modified Joule-Thomson equation (17), both c and n have simple theoretical interpretations, and it is possible to express the thermodynamical properties of the substance in terms of them by means of reasonably simple formulae.

12. *Application of the Modified Equation.*—We may take equation (17) as a practical example of the thermodynamical principles already given. The values of the partial differential coefficients in terms of n and c are as follows:—

$$dv/d\theta\ (p\ \text{const})=(R/p)(1+nc/V) \quad . \quad . \quad . \quad . \quad . \quad (19)$$
$$d^2v/d\theta^2\ \ ,, \quad = -n(n+1)c/\theta^2 \quad . \quad . \quad . \quad . \quad . \quad (20)$$
$$dp/d\theta\ (v\ \text{const})=(R/V)(1+nc/V) \quad . \quad . \quad . \quad . \quad (21)$$
$$d^2p/d\theta^2\ \ ,, \quad =Rnc(1-n+2nc/V)/\theta V^2 \quad . \quad . \quad . \quad (22)$$
$$d(pv)/dp(\theta\ \text{const})=b-c \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (23)$$

Substituting these values in equations already given, we find,

from (6) $\quad S-s=R(1+nc/V)^2 \quad . \quad . \quad . \quad . \quad . \quad (24)$

,, (9) $dE/dv\ (\theta\ \text{const})=ncp/V \quad . \quad . \quad . \quad . \quad . \quad . \quad (25)$

,, (11) $dF/dp \quad ,, \quad =(n+1)c-b \quad . \quad . \quad . \quad . \quad . \quad . \quad (26)$

,, (10) $ds/dv \quad ,, \quad =(1-n+2nc/V)Rnc/V^2 \quad . \quad . \quad . \quad (27)$

,, (12) $dS/dp \quad ,, \quad =n(n+1)c/\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad (28)$

In order to deduce the complete variation of the specific heats from these equations, it is necessary to make some assumption with regard to the variation of the specific heats with temperature. The assumption usually made is that the total kinetic energy of the molecules, including possible energy of rotation or vibration if the molecules consist of more than one atom, is proportional to the energy of translation in the case of an ideal gas. In the case of imperfect gases, all the available experimental evidence shows that the specific volume tends towards its ideal value, $V=R\theta/p$, in the limit, when the pressure is indefinitely reduced and the molecules are widely separated so as to eliminate the effects of their mutual actions. We may therefore reasonably assume that the *limiting* values of the specific heats at zero pressure do not vary with the temperature, provided that the molecule is stable and there is no dissociation. Denoting by S_0, s_0, these constant limiting values at $p=0$, we may obtain the values at any pressure by integrating the expressions (27) and (28) from ∞ to v and from 0 to p respectively. We thus obtain

$$S=S_0+n(n+1)pc/\theta \quad . \quad . \quad . \quad . \quad . \quad (29)$$
$$s=s_0+(n-1-nc/V)ncp/\theta \quad . \quad . \quad . \quad . \quad (30)$$

In working to a first approximation, the small term nc/V may be omitted in the expression for s.

The expression for the change of intrinsic energy E between any given limits $p_0\theta_0$ to $p\theta$ is readily found by substituting these values of the specific heats in equations (11) or (13), and integrating between the given limits. We thus obtain

$$E-E_0=s_0(\theta-\theta_0)-n(pc-p_0c_0) \quad . \quad . \quad . \quad (31)$$

We have similarly for the total heat $F=E+pv$,

$$F-F_0=S_0(\theta-\theta_0)-(n+1)(cp-c_0p_0)+b(p-p_0).$$

The energy is less than that of an ideal gas by the term npc. If we imagine that the defect of volume c is due to the formation of molecular aggregates consisting of two or more single molecules, and if the kinetic energy of translation of any one of these aggregates is equal to that of one of the single molecules, it is clear that some energy must be lost in co-aggregating, but that the proportion lost will be different for different types of molecules and also for different types of co-aggregation. If two monatomic molecules, having energy of translation only, equivalent to 3 degrees of freedom, combined to form a diatomic molecule with 5 degrees of freedom, the energy lost would be $pc/2$ for co-aggregation, c, per unit mass. In this case $n=1/2$. If two diatomic molecules, having each 5 degrees of freedom, combine to form a molecule with 6 degrees of freedom, we should have $n=2$, or the energy lost would be $2pc$ per unit mass. If the molecules and molecular aggregates were more complicated, and the number of degrees of freedom of the aggregates were limited to 6, or were the same as for single molecules, we should have $n=s_0/R$. The loss of energy could not be greater than this on the simple kinetic theory, unless there were some evolution of latent heat of co-aggregation, due to the work done by the mutual attractions of the co-aggregating molecules.

It is not necessary to suppose that the co-aggregated molecules are permanently associated. They are continually changing partners, the ratio c/V representing approximately the ratio of the time during which any one molecule is paired to the time during which it is free. At higher densities it is probable that more complex aggregates would be formed, so that as the effect of the collisions became more important c would cease to be a function of the temperature only; experiment, indeed, shows this to be the case.

13. *Entropy.*—It follows from the definition of the absolute scale of temperature, as given in relations (2), that in passing at constant temperature θ from one adiabatic ϕ' (Fig. 1) to any other adiabatic ϕ'', the quotient H/θ of the heat absorbed by the temperature at which it is absorbed is the same for the same two adiabatics whatever the temperature of the isothermal path. This quotient is called the change of entropy, and may be denoted by $(\phi''-\phi')$. In passing along an adiabatic there is no change of entropy, since no heat is absorbed. The adiabatics are lines of constant entropy, and are also called *Isentropics*. In virtue of relations (2), the change of entropy of a substance between any two states depends only on the initial and final states, and may be reckoned along any reversible path, not necessarily isothermal, by dividing each small increment of heat, dH, by the temperature, θ, at which it is acquired, and taking the sum or integral of the quotients, dH/θ, so obtained.

The expression for the change of entropy between any two states is found by dividing either of the expressions for dH in (8) by θ and integrating between the given limits, since dH/θ is a perfect differential. In the case of a solid or a liquid, the latent heat of isothermal expansion may often be neglected, and if the specific heat, s, be also taken as constant, we have simply $\phi-\phi_0=s\log_e\theta/\theta_0$. If the substance at the temperature θ undergoes a change of state, absorbing latent heat, L, we have merely to add the term L/θ to the above expression. In the case of an ideal gas, $dp/d\theta$ at constant volume $=R/v$, and $dv/d\theta$ at constant pressure $=R/p$; thus we obtain the expressions for the change of entropy $\phi-\phi_0$ from the state $p_0\theta_0v_0$ to the state $p\theta v$,

$$\begin{aligned}\phi-\phi_0&=s\log_e\theta/\theta_0+R\log_e v/v_0\\&=S\log_e\theta/\theta_0-R\log_e p/p_0 \quad . \quad . \quad . \quad (32)\end{aligned}$$

In the case of an imperfect gas or vapour, the above expressions are frequently employed, but a more accurate result may be obtained by employing equation (17) with the value of the specific heat, S, from (29), which gives the expression

$$\phi-\phi_0=S_0\log_e\theta/\theta_0-R\log_e p/p_0-n(cp/\theta-c_0p_0/\theta_0) \quad . \quad . \quad (33)$$

The state of a substance may be defined by means of the temperature and entropy as co-ordinates, instead of employing the pressure and volume as in the indicator diagram. This method of representation is applicable to certain kinds of problems, and has been developed by Macfarlane Gray and other writers in its application to the steam engine. (See STEAM ENGINE.) Areas on the temperature-entropy or θ, ϕ diagram represent quantities of heat in the same way as areas on the indicator diagram represent quantities of work. The θ, ϕ diagram is useful in the study of heat waste and condensation, but from other points of view the utility of the conception of entropy as a "factor of heat" is limited by the fact that it does not correspond to any directly measurable physical property, but is merely a mathematical function arising from the form of the definition of absolute temperature. Changes of entropy must be calculated in terms of quantities of heat, and must be interpreted in a similar manner. The majority of thermodynamical problems may be treated without any reference to entropy, but it affords a convenient method of expression in abstract thermodynamics, especially in the consideration of irreversible processes and in reference to the conditions of equilibrium of heterogeneous systems.

14. *Irreversible Processes.*—In order that a process may be strictly reversible, it is necessary that the state of the working substance should be one of equilibrium at uniform pressure and temperature throughout. If heat passes "of itself" from a higher to a lower temperature by conduction, convection or radiation, the transfer cannot be reversed without an expenditure of work. If mechanical work or kinetic energy is directly converted into heat by friction, reversal of the motion does not restore the energy so converted. In all such cases there is necessarily, by Carnot's principle, a loss of efficiency or available energy, accompanied by an increase of entropy, which serves as a convenient measure or criterion of the loss. A common illustration of an irreversible process is the expansion of a gas into a vacuum or against a pressure less than its own. In this case the work of expansion, pdv, is expended in the first instance in producing kinetic energy of motion of parts of the gas. If this could be co-ordinated and utilized without dissipation, the gas might conceivably be restored to its initial state; but in practice violent local differences of pressure and temperature are produced, the kinetic energy is rapidly converted into heat by viscous eddy friction, and residual differences of temperature are equalized by diffusion throughout the mass. Even if the expansion is adiabatic, in the sense that it takes place inside a non-conducting enclosure and no heat is supplied from external sources, it will not be isentropic, since the heat supplied by internal friction must be included in reckoning the change of entropy. Assuming that no heat is supplied from external sources and no external work is done, the intrinsic energy remains constant by the first law. The final state of the substance, when equilibrium has been restored, may be deduced from this condition, if the energy can be expressed in terms of the co-ordinates. But the line of constant energy on the diagram does not represent the path of the transformation, unless it be supposed to be effected in a series of infinitesimal steps between each of which the substance is restored to an equilibrium state. An irreversible process which permits a more complete experimental investigation is the steady flow of a fluid in a tube already referred to in section 10. If the tube is a perfect non-conductor, and if there are no eddies or frictional dissipation, the state of the substance at any point of the tube as to E, p, and v, is represented by the adiabatic or isentropic path, $dE=-pdv$. As the section of the tube varies, the change of kinetic energy of flow, dU, is represented by $-vdp$. The flow in this case is reversible, and the state of the fluid is the same at points where the section of the tube is the same. In practice, however, there is always some frictional dissipation, accompanied by an increase of entropy and by a fall of pressure. In the limiting case of a long fine tube, the bore of which varies in such a manner that U is constant, the state of the substance along a line of flow may be represented by the line of constant total heat, $d(E+pv)=0$; but in the case of a porous plug or small throttling aperture, the steps of the process cannot be followed, though the final state is the same.

In any small reversible change in which the substance absorbs heat, dH, from external sources, the increase of entropy, $d\phi$, must be equal to dH/θ. If the change is not reversible, but the final state is the same, the change of entropy, $d\phi$, is the same, but it is no longer equal to dH/θ. By Carnot's principle, in all irreversible processes, dH/θ must be algebraically less than $d\phi$, otherwise it would be possible to devise a cycle more efficient than a reversible cycle. This affords a useful criterion (see ENERGETICS) between transformations which are impossible and those which are possible but irreversible. In the special case of a substance isolated from external heat supply, $dH=0$, the change of entropy is zero in a reversible process, but must be positive if the process is not reversible. The entropy cannot diminish. Any change involving decrease of entropy is impossible. The entropy tends to a maximum, and the state is one of stable equilibrium when the value of the entropy is the maximum value consistent with the conditions of the problem.

15. *Heterogeneous Equilibrium.*—In a *system*, as distinguished from a homogeneous substance, consisting of two or more states or phases, a similar condition of equilibrium applies. In any spontaneous irreversible change, if the system is heat-isolated, there must be an increase of entropy. The total entropy of the system is found by multiplying the entropy per unit mass of the substance in each state by the mass existing in that state, and adding the products so obtained. The simplest case to consider is that of equilibrium between solid and liquid, or liquid and vapour. The more general case is discussed in the article ENERGETICS, and in the original memoirs of Willard Gibbs and others. Since the condition of heat-isolation is impracticable, the condition of maximum entropy cannot, as a rule, be directly applied, and it is necessary to find a more convenient method of expression. If dW is the external work done, dH the heat absorbed from external sources, and dE the increase of intrinsic energy, we have in all cases by the first law, $dH-dE=dW$. Since $\theta d\phi$ cannot be less than dH, the difference $(\theta d\phi-dE)$ cannot be less than dW. This inequality holds in all cases, but cannot in general be applied to an irreversible change, because $\theta d\phi$ is not a perfect differential, and cannot be evaluated without a knowledge of the path or process of transformation. In the special case, however, in which the transformation is conducted in an isothermal enclosure, a common condition easily realized in practice, the temperature at the end of the transformation is reduced to its initial value throughout the substance. The value of $\theta d\phi$ is then the same as $d(\theta\phi)$, which is a perfect differential, so that the condition may be written $d(\phi\theta-E)=dW$. The condition in this form can be readily applied provided that the external work dW can be measured. There are two special cases of importance:—(*a*) If the volume is constant, or $dW=0$, the value of the function $(\theta\phi-E)$ cannot diminish, or $(E-\theta\phi)$ cannot increase, if the temperature is kept constant. This function may be represented, for each state or phase of the system considered, by an area on the indicator diagram similar to that representing the intrinsic energy, E. The product $\theta\phi$ may be represented at any point such as D in Fig. 1 by the whole area θ''DZ′VO under the isothermal θ''D and the adiabatic DZ′, bounded by the axes of pressure and volume. The intrinsic energy, E, is similarly represented by the area DZ′V*d* under the adiabatic to the right of the isometric D*d*. The difference $\theta\phi-E$ is represented by the area θ''D*d*O to the left of the isometric D*d* under the isothermal θ''D. The increment of this area (or the decrement of the negative area $E-\theta\phi$) at constant temperature represents the external work obtainable from the substance in isothermal expansion, in the same way that the decrement of the intrinsic energy represents the work done in adiabatic expansion. The function $J=E-\theta\phi$, has been called the "free energy" of the substance by Helmholtz, and $\theta\phi$ the "bound energy." These functions do not, however, represent energy existing in the substance, like the intrinsic energy; but the increment of $\theta\phi$ represents heat supplied to, and the decrement of $(E-\theta\phi)$ represents work obtainable from, the substance when the temperature is kept constant. The condition of stable equilibrium of a system at constant temperature and volume is that the total J should be a minimum. This function is also called the "thermodynamic potential at constant volume" from the analogy with the condition of minimum potential energy as the criterion of stable equilibrium in statics.

As an example, we may apply this condition to the case of change of state. If J', J'' represent the values of the function for unit mass of the substance of specific volumes v' and v'' in the two states at temperature θ and pressure p, and if a mass m is in the state v', and $1-m$ in the state v'', the value of J for unit mass of the mixture is $mJ'+(1-m)J''$. This must be a minimum in the state of equilibrium at constant temperature. Since the volume is constant, we have the condition $mv'+(1-m)v''=$constant. Since $dJ=-\phi d\theta-pdv$, we have also the relations $dJ'/dv'=-p=dJ''/dv''$, at constant temperature. Putting $dJ/dm=0$ at constant volume, we obtain as the condition of equilibrium of the two states $J'+p'v'=J''+p''v''$. This may be interpreted as the equation of the border curve giving the relation between p and θ, but is more easily obtained by considering the equilibrium at constant pressure instead of constant volume.

(*b*) The second case, which is of greater practical utility, is that in which the external pressure, p, is kept constant. In this case $dW=pdv=d(pv)$, a perfect differential, so that the external work done is known from the initial and final states. In any possible transformation $d(\theta\phi-E)$ cannot be less than $d(pv)$, or the function $(E-\theta\phi+pv)=G$ cannot increase. The condition of stable equilibrium is that G should be a minimum, for which reason it has been called the "thermodynamic potential at constant pressure." The product pv for any state such as D in fig. 1 is represented by the rectangle MDdO, bounded by the isopiestic and the isometric through D. The function G is represented by the negative area θ''DM under the isothermal, bounded by the isopiestic DM and the axis of pressure. The increment of $\theta\phi$ is always greater than that of the total heat $F=E+pv$, except in the special case of an equilibrium change at constant temperature and pressure, in which case both are equal to the heat absorbed in the change, and the function G remains constant. This is geometrically obvious from the form of the area representing the function on the indicator diagram, and also follows directly from the first law. The simplest application of the thermodynamic potential is to questions of change of state. If ϕ', E', v'; and ϕ'', E'', v'', refer to unit mass of the substance in the first and second states respectively in equilibrium at a temperature θ and pressure p, the heat absorbed, L, per unit mass in a change from the first to the second state is, by definition of the entropy, equal to $\theta(\phi''-\phi')$, and this by the first law is equal to the change of intrinsic energy, $E''-E'$, plus the external work done, $p(v''-v')$, *i.e.* to the change of total heat, $F''-F$. If G' and G'' are the values of the function G for the two states in equilibrium at the same pressure and temperature, we must have $G'=G''$. Assuming the function G to be expressed in terms of p and θ, this condition represents the relation between p and θ corresponding to equilibrium between the two states, which is the solution of the relation $(v''-v')dp/d\theta=L/\theta$, (5). The direct integration of this equation requires that L and $v''-v'$ should be known as functions of p and θ, and cannot generally be performed. As an example of one of the few cases where a complete solution is possible, we may take the comparatively simple case equation (17), already considered, which is approximately true for the majority of vapours at moderate pressures.

Writing formulae (31) and (33) for the energy and entropy with indeterminate constants A and B, instead of taking them between limits, we obtain the following expressions for the thermodynamic functions in the case of the vapour:—

$$\phi''=S_0\log_e\theta-R\log_e p-ncp/\theta+A'' \quad (34)$$
$$E''=s_0\theta-ncp+B'' \quad (35)$$
$$F''=S_0\theta-(n+1)cp+bp+B'' \quad (36)$$
$$G''=S_0\theta(1-\log_e\theta)+R\theta\log_e p-(c-b)p-A''\theta+B'' \quad (37)$$
$$J''=s_0\theta-S_0\theta\log_e\theta+R\theta\log_e p-A''\theta+B'' \quad (38)$$

The function J'' may be expressed in terms of θ and v by writing for p its value, namely, $R\theta/(v+c-b)$. We have also in any case the relations

$$dG''/d\theta\ (p\ \text{const})=\phi''=dJ''/d\theta\ (v\ \text{const}) \quad (39)$$
$$dG''/dp\ (\theta\ \text{const})=v,\ dJ''/dv\ (\theta\ \text{const})=p \quad (40)$$

And all the properties of the substance may be expressed in terms of G or J and their partial differential coefficients. The values of the corresponding functions for the liquid or solid cannot be accurately expressed, as the theoretical variation of the specific heat is unknown, but if we take the specific heat at constant pressure s' to be approximately constant, and observe the small residual variation dh of the total heat, we may write

$$F'=s'\theta+dh+B' \quad (41)$$
$$\phi'=s'\log_e\theta+d\phi+A' \quad (42)$$
$$G'=s'\theta(1-\log_e\theta)+(dh-\theta d\phi)-A'\theta+B' \quad (43)$$

where $d\phi$ is the corresponding residual variation of ϕ', and is easily calculated from a table of values of h.

To find the border curve of equilibrium between the two states, giving the saturation pressure as a function of the temperature, we have merely to equate the values of G' and G''. Rearranging the terms, and dividing throughout by θ, we obtain an equation of the form

$$R\ \log_e p=A-B/\theta-(s'-S_0)\log_e\theta+(c-b)p/\theta+(dh/\theta-d\phi) \quad (44)$$

in which $B=B''-B'$, and $A=A''-A'+s'-S_0$. The value of A is determined by observing the value of θ_0 at some known pressure p_0, *e.g.* at the boiling-point. The value of B is determined by observing the latent heat, $L_0=F''_0-F'_0$, which gives

$$B=B''-B'=L_0+(s'-S_0)\theta_0+(n+1)c_0p_0-bp_0+dh_0 \quad (45)$$

This constant may be called the absolute latent heat, as it expresses the thermal value of the change of state in a manner independent of temperature.

The term $(dh/\theta-d\phi)$ depending on the variation of the specific heat of the liquid may be made very small in the case of water by a proper choice of the constant s'. It is of the same order as the probable errors of observation, and may be neglected in practice. (See VAPORIZATION, § 16.) The expression for $R\log p$ for an imperfect gas of this type differs from that for a perfect gas only by the addition of the term $(c-b)p/\theta$. This simple result is generally true, and the corresponding expressions for G'' and J'' are valid, provided that $c-b$ in formula (17) is a function of the temperature only. It is not necessary to suppose that c varies inversely as the nth power of the temperature, and that b is constant, as assumed in deducing the expressions for ϕ, E, and F.

Although the value of G in any case cannot be found without that of ϕ, and although the consideration of the properties of the thermodynamic potential cannot in any case lead to results which are not directly deducible from the two fundamental laws, it affords a convenient method of formal expression in abstract thermodynamics for the condition of equilibrium between different phases, or the criterion of the possibility of a transformation. For such purely abstract purposes, the possibility of numerical evaluation of the function is of secondary importance, and it is often possible to make qualitative deductions with regard to the general nature of a transformation without any knowledge of the actual form of the function. A more common method of procedure, however, is to infer the general relations of the thermodynamic potential from a consideration of the phenomena of equilibrium.

As it would be impossible within the limits of this article to illustrate or explain adequately the applications which have been made of the principles of thermodynamics, it has been necessary to select such illustrations only as are required for other reasons, or could not be found elsewhere. For fuller details and explanations of the elements of the subject, the reader must be referred to general treatises such as Baynes's *Thermodynamics* (Oxford), Tait's *Thermodynamics* (Edinburgh), Maxwell's *Theory of Heat* (London), Parker's *Thermodynamics* (Cambridge), Clausius's *Mechanical Theory of Heat* (translated by Browne, London), and Preston's *Theory of Heat* (London). One or two chapters on the subject are also generally included in treatises on the steam engine, or other heat engines, such as those of Rankine, Perry or Ewing. Of greater interest, particularly from a historical point of view, are the original papers of Joule, Thomson and Rankine, some of which have been reprinted in a collected form. A more complete and more elaborate treatment of the subject will be found in foreign treatises, such as those of Clausius, Zeuner, Duhem, Bertrand, Planck and others.

THERMOELECTRICITY. 1. *Fundamental Phenomena.*—Alessandro Volta (1801) showed that although a separation of the two electricities was produced by the contact of two different metals (*Volta Effect*), which could be detected by a sensitive electrometer, a continuous current of corresponding magnitude could not be produced in a purely metallic circuit without the interposition of a liquid, because the electromotive force at one junction was exactly balanced by an equal and opposite force at the other. T. J. Seebeck (1822), employing a galvanometer then recently invented, which was more suited for the detection of small electromotive forces, found that a current was produced if the junctions of the two metals were at different temperatures. He explained this effect by supposing that the Volta contact electromotive force varied with the temperature, so that the exact balance was destroyed by unequal heating. The intensity of the current, C, for any given pair of metals, was found to vary directly as the difference of temperature, $t-t'$, between the hot and cold junctions, and inversely as the resistance, R, of the circuit. We conclude by applying Ohm's law that the electromotive force, E, of the thermocouple may be approximately represented for small differences of temperature by the formula

$$E=CR=p(t-t') \quad . \quad . \quad . \quad . \quad . \quad (1)$$

2. *Thermoelectric Power, Series, Inversion.*—The limiting value, dE/dt, of the coefficient, p, for an infinitesimal difference, dt, between the junctions is called the *Thermoelectric Power* of the couple. One metal (A) is said to be thermoelectrically positive to another (B), if positive electricity flows from A to B across the cold junction when the circuit is completed. The opposite convention is sometimes adopted, but the above is the most convenient in practice, as the circuit is generally broken at or near the cold junction for the insertion of the galvanometer. Seebeck found that the metals could be arranged in a *Thermoelectric Series*, in the order of their power when combined with any one metal, such that the power of any thermocouple p, composed of the metals A and B, was equal to the algebraic difference $(p'-p'')$ of their powers when combined with the standard metal C. The order of the metals in this series was found to be different from that in the corresponding Volta series, and to be considerably affected by variations in purity, hardness and other physical conditions. J. Cumming shortly afterwards discovered the phenomenon of *Thermoelectric Inversion*, or the change of the order of the metals in the thermoelectric series at different temperatures. Copper, for instance, is negative to iron at ordinary temperatures, but is positive to it at 300° C. or above. The E.M.F. of a copper-iron thermocouple reaches a maximum when the temperature of the hot junction is raised to 270° C., at which temperature the thermoelectric power vanishes and the metals are said to be *neutral* to one another. Beyond this point the E.M.F. diminishes, vanishing and changing sign when the temperature of the hot junction is nearly as much above the neutral point as the temperature of the cold junction is below it. Similar phenomena occur in the case of many other couples, and it is found that the thermoelectric power p is not in general a constant, and that the simple linear formula (1) is applicable only for small differences of temperature. More accurately it may be stated that the thermoelectromotive force in any given circuit containing a series of different metals is a function of the temperatures of the junctions only, and is independent of the distribution of the temperature at any intermediate points, provided that each of the metals in the series is of uniform quality. This statement admits of the simple mathematical expression

$$E=\int_{t_0}^{t'} p'dt+\int_{t'}^{t''} p''dt + \&c. \quad . \quad . \quad . \quad (2)$$

where p', p, &c., are the thermoelectric powers of the metals, and t_0, t', t'', &c., the temperatures of the junctions. There are some special cases of sufficient practical importance to be separately stated.

3. *Homogeneous Circuit. Strain Hysteresis.*—In a circuit consisting of a single metal, no current can be produced by variations of temperature, provided that the metal is not thereby strained or altered. This was particularly demonstrated by the experiments of H. G. Magnus. The effects produced by abrupt changes of temperature or section, or by pressing together pieces of the same metal at different temperatures, are probably to be explained as effects of strain. A number of interesting effects of this nature have been investigated by Thomson, F. P. Le Roux, P. G. Tait and others, but the theory has not as yet been fully developed. An interesting example is furnished by an experiment due to F. T. Trouton (*Proc. R. S. Dub.*, 1886). A piece of iron or steel wire in the circuit of a galvanometer is heated in a flame to bright redness at any point. No effect is noticed so long as the flame is stationary, but if the flame be moved slowly in one direction a current is observed, which changes its direction with the direction of motion of the flame. The explanation of this phenomenon is that the metal is transformed at a red heat into another modification, as is proved by simultaneous changes in its magnetic and electrical properties. The change from one state to the other takes place at a higher temperature on heating than on cooling. The junctions of the magnetic and the non-magnetic steel are therefore at different temperatures if the flame is moved, and a current is produced just as if a piece of different metal with junctions at different temperatures had been introduced into the circuit. Other effects of "hysteresis" occur in alloys of iron, which have been studied by W. F. Barrett (*Trans. R. S. Dub.*, January 1900).

4. *Law of Successive Temperatures.*—The E.M.F. of a given couple between any temperatures t' and t'' is the algebraic sum of the E.M.F. between t' and any other temperature t and the E.M.F. between t' and t''. A useful result of this law is that it is sufficient to keep one junction always at some convenient standard temperature, such as 0° C., and to tabulate only the values of the E.M.F. in the circuit corresponding to different temperatures of the other junction.

5. *Law of Intermediate Metals.*—A thermoelectric circuit may be cut at any point and a wire of some other metal introduced without altering the E.M.F. in the circuit, provided that the two junctions with the metal introduced are kept at the same temperature. This law is commonly applied in connecting a thermocouple to a galvanometer with coils of copper wire, the junctions of the copper wires with the other metals being placed side by side in a vessel of water or otherwise kept at the same temperature. Another way of stating this law, which, though apparently quite different, is really equivalent in effect, is the following. The E.M.F. of any couple, AB, for any given limits of temperature is the algebraic sum of the E.M.F.s between the same limits of temperature of the couples BC and CA formed with any other metal C. It is for this reason unnecessary to tabulate the E.M.F.s of all possible combinations of metals, since the E.M.F. of any couple can be at once deduced by addition from the values given by its components with a single standard metal. Different observers have chosen different metals as the standard of reference. Tait and J. A. Fleming select lead on account of the smallness of the Thomson effect in it, as observed by Le Roux. Noll adopts mercury because it is easily purified, and its physical condition in the liquid state is determinate; there is, however, a discontinuity involved in passing from the liquid to the solid state at a temperature of −40° C., and it cannot be used at all with some metals, such as lead, on account of the rapidity with which it dissolves them. Both lead and mercury have the disadvantage that they cannot be employed for temperatures much above 300° C. Of all metals, copper is the most generally convenient, as it is always employed in electrical connexions and is easily obtained in the annealed state of uniform purity. For high temperature work it is necessary to employ platinum, which would be an ideal standard for all purposes on account of its constancy and infusibility, did not the thermoelectric properties of different specimens differ considerably.

6. *Thermoelectric Formulae.*—On the basis of the principles stated above, the most obvious method of tabulating the observations would be to give the values E_t of the E.M.F. between 0° C. and t for each metal against the standard. This involves no assumptions as to the law of variation of E.M.F. with temperature, but is somewhat cumbrous. In the majority of cases it is found that the observations can be represented within the limits of experimental error by a fairly simple empirical formula, at least for moderate ranges of temperatures. The following formulae are some of those employed for this purpose by different observers:—

$E_t=bt+ct^2$	(Avenarius, 1863.)
$E_t=at+bt^2+ct^3$	(General type.)
$\log E=a+b/T+c \log T$ . . .	(Becquerel, 1863.)
$E_{(t-t')}=c(t-t')\,(2t^\circ-(t+t'))$ . .	(Tait, 1870)
$E_t+E_{t^\circ}=10^{a+bt}+10^{a'+b't^\circ}$ . . .	(Barus, 1889.)
$t=aE+bE^2+cE^3$	(Holborn and Wien, 1892.)
$E_{(t-t')}=b(t-t')^{4/3}$	(Paschen, 1893.)
$E_{(t-t')}=a(t-t')+b(t-t')^2$ . . .	(Steele, 1894.)
$E_{(T-T^\circ)}=mT^n-mT^{\circ n}$, $E_t=mt^n$ . .	(Holman, 1896.)
$E_t=bt+c \log T/273$, $(c=Ts.)$ . .	(Stanfield, 1898.)
$E_t=-a+bt+ct^2$	(Holborn and Day, 1899.)

$E_t=at+ct^2+s^\circ(T \log_e T-273 \log_e 273)$.
(Where $s=s^\circ+2cT$, and c is small. See sec. 15.)

For moderate ranges of temperature the binomial formula of M. P. Avenarius is generally sufficient, and has been employed by many observers. It is figured by Avenarius (*Pogg. Ann.*, 119, p. 406) as a semi-circle, but it is really a parabola with its axis parallel to the axis of E, and its vertex at the point $t=-b/2c$, which gives the neutral temperature. We have also the relations $dE/dt=b+2ct$ and $d^2E/dt^2=2c$. The first relation gives the thermoelectric power p at any temperature, and is probably the most convenient method of stating results in all cases in which this formula is applicable. A discussion of some of the exponential formulae is given by S. W. Holman (*Phil. Mag.*, 41, p. 465, June 1896).

7. *Experimental Results.*—In the following comparative table of the results of different observers the values are referred to lead. Before the time of Tait's researches such data were of little interest or value, on account of insufficient care in securing the purity of the materials tested; but increased facilities in this respect, combined with great improvements in electrical measurements, have put the question on a different footing. The comparison of independent results shows in many cases a remarkable concordance, and the data are becoming of great value for the testing of various theories of the relations between heat and electricity.

TABLE I.—THERMOELECTRIC POWER, $p=dE/dt$, IN MICROVOLTS AT 50° C. OF PURE METALS WITH RESPECT TO LEAD. (The mean change, $2c=d^2E/dt^2$, of the thermoelectric power per degree C. over the range covered by the experiments, is added in each case.)

Explanation of Table.—The figures marked with an asterisk (*) represent discrepancies which are probably caused by impurities in the specimens. At the time of Tait's work in 1873 it was difficult, if not impossible, in many cases to secure pure materials. The work of the other three observers dates from 1894–95. The value of the thermoelectric power dE/dt at 50° C. is taken as the mean value between 0° and 100° C., over which range it can be most accurately determined. The values of d^2E/dt^2 agree as well as can be expected, considering the difference of the ranges of temperature and the great variety in the methods of observation adopted; they are calculated assuming the parabolic formula, which is certainly in many cases inadequate. Noll's values apply to the temperature of +100° C., Dewar and Fleming's to that of −100° C., approximately.

In using the above table to find the value of E or dE/dt at any temperature or between any limits, denoting by p the value of dE/dt at 50° C., and by $2c$ the constant value of the second coefficient, we have the following equations:—

$$dE/dt=p+2c(t-50), \text{ at any temperature } t, \text{ Cent.} \quad (3)$$

$$E_{(t-t')}=(t-t')(p+c(t+t'-100)) \quad (4)$$

for the E.M.F. between any temperature t and t'.

8. *Methods of Observation.*—In Tait's observations the E.M.F. was measured by the deflection of a mirror galvanometer, and the temperature by means of a mercury thermometer or an auxiliary thermocouple. He states that the deviations from the formula were "quite within the limits of error introduced by the alteration of the resistance of the circuit with rise of temperature, the deviations of the mercury thermometers from the absolute scale, and the non-correction of the indications of the thermometer for the long column of mercury not immersed in the hot oil round the junctions." The latter correction may amount to about 10° C. at 350°. Later observers have generally employed a balance method (some modification of the potentiometer or Poggendorf balance) for measuring the E.M.F. The range of Steele's observations was too small to show any certain deviation from the formula, but he notes capricious changes attributed to change of condition of the wires. Noll employed mercury thermometers, but as he worked over a small range with vapour baths, it is probable that he did not experience any trouble from immersion corrections. He does not record any systematic deviations from the formula. Dewar and Fleming, working at very low temperatures, were compelled to use the platinum thermometer, and expressed their results in terms of the platinum scale. Their observations were probably free from immersion errors, but they record some deviations from the formula which they consider to be beyond the possible limits of error of their work. The writer has reduced their results to the scale of the gas thermometer, assuming the boiling-point of oxygen to be −182·5° C.

9. *Peltier Effect.*—The discovery by J. C. A. Peltier (1834) that heat is absorbed at the junction of two metals by passing a current through it in the same direction as the current produced by heating it, was recognized by Joule as affording a clue to the source of the energy of the current by the application of the principles of thermodynamics. Unlike the frictional generation of heat due to the resistance of the conductor, which Joule (1841) proved to be proportional to the square of the current, the Peltier effect is reversible with the current, and being directly proportional to the first power of the current, changes sign when the current is reversed. The effect is most easily shown by connecting a voltaic cell to a thermopile for a short interval, then quickly (by means of a suitable key, such as a Pohl commutator with the cross connectors removed) disconnecting the pile from the cell and connecting it to a galvanometer, which will indicate a current in the reverse direction through the pile, and approximately proportional to the original current in intensity, provided that the other conditions of the experiment are constant. It was by an experiment of this kind that Quintus Icilius (1853) verified the proportionality of the heat absorbed or generated to the first power of the current. It had been observed by Peltier and A. E. Becquerel that the intensity of the effect depended on the thermoelectric power of the junction and was independent of its form or dimensions. The order of the metals in respect of the Peltier effect was found to be the same as the thermoelectric series. But on account of the difficulty of the measurements involved, the verification of the accurate relation between the Peltier effect and thermoelectric power was left to more recent times. If C is the intensity of the current through a simple thermocouple, the junctions of which are at temperatures t and t', a quantity of heat, $P\times C$, is absorbed by the passage of the current per second at the hot junction, t, and a quantity, $P'\times C$, is evolved at the cold junction, t'. The coefficients, P and P', are called coefficients of the Peltier effect, and may be stated in calories or joules per ampere-second. The Peltier coefficient may also be expressed in volts or microvolts, and may be regarded as the measure of an E.M.F. located

at the junction, and transforming heat into electrical energy or vice versa. If R is the whole resistance of the circuit, and E the E.M.F. of the couple, and if the flow of the current does not produce any other thermal effects in the circuit besides the Joule and Peltier effects, we should find by applying the principle of the conservation of energy, *i.e.* by equating the balance of the heat absorbed by the Peltier effects to the heat generated in the circuit by the Joule effect,

$$(P-P')C=C^2R=EC, \text{ whence } E=P-P' \quad . \quad . \quad (5)$$

If we might also regard the couple as a reversible thermodynamic engine for converting heat into work, and might neglect irreversible effects, such as conduction, which are independent of the current, we should expect to find the ratio of the heat absorbed at the hot junction to the heat evolved at the cold junction, namely, P/P', to be the same as the ratio T/T' of the absolute temperatures of the junctions. This would lead to the conclusion given by R. J. E. Clausius (1853) that the Peltier effect varied directly as the absolute temperature, and that the E.M.F. of the couple should be directly proportional to the difference of temperature between the junctions.

10. *Thomson Effect.*—Thomson (Lord Kelvin) had already pointed out (*Proc. R.S. Edin.*, 1851) that this conclusion was inconsistent with the known facts of thermoelectric inversion. (1) The E.M.F. was not a linear function of the temperature difference. (2) If the Peltier effect was proportional to the thermoelectric power and changed sign with it, as all experiments appeared to indicate, there would be no absorption of heat in the circuit due to the Peltier effect, and therefore no thermal source to account for the energy of the current, in the case in which the hot junction was at or above the neutral temperature. He therefore predicted that there must be a reversible absorption of heat in some other part of the circuit due to the flow of the current through the unequally heated conductors. He succeeded a few years afterwards in verifying this remarkable prediction by the experimental demonstration that a current of positive electricity flowing from hot to cold in iron produced an absorption of heat, as though it possessed *negative* specific heat in the metal iron. He also succeeded in showing that a current from hot to cold evolved heat in copper, but the effect was smaller and more difficult to observe than in iron.

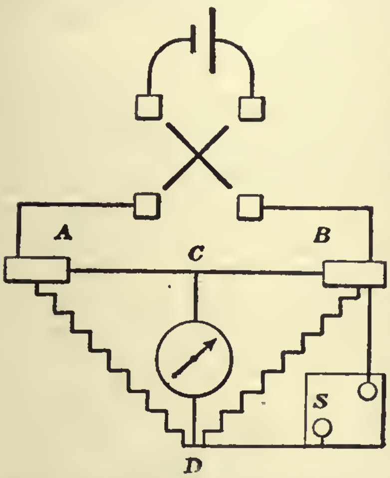

Fig. 1.—Diagram of Apparatus for Demonstrating the Thomson Effect.

The Thomson effect may be readily demonstrated as a lecture experiment by the following method (fig. 1). A piece of wire (No. 28) about 4 cm. long is soldered at either end A, B to thick wires (No. 12), and is heated 100° to 150° C. by a steady current from a storage cell adjusted by a suitable rheostat. The experimental wire AB is connected in parallel with about 2 metres of thicker wire (No. 22), which is not appreciably heated. A low-resistance galvanometer is connected by a very fine wire (2 to 3 mils) to the centre C of the experimental wire AB, and also to the middle point D of the parallel wire so as to form a Wheatstone bridge. The balance is adjusted by shunting either AD or BD with a box, S, containing 20 to 100 ohms. All the wires in the quadrilateral must be of the same metal as AB, to avoid accidental thermoelectric effects which would obscure the result. If the current flows from A to B there will be heat absorbed in AC and evolved in CB by the Thomson effect, if the specific heat of electricity in AB is positive as in copper. When the current is reversed, the temperature of AC will be raised and that of CB lowered by the reversal of the effect. This will disturb the resistance balance by an amount which can be measured by the deflection of the galvanometer, or by the change of the shunt-box, S, required to restore the balance. Owing to the small size of the experimental wire, the method is very quick and sensitive, and the apparatus can be set up in a few minutes when once the experimental quadrilaterals have been made. It works very well with platinum, iron and copper. It was applied with elaborate modifications by the writer in 1886 to determine the value of the Thomson effect in platinum in absolute measure, and has recently been applied with further improvements by R. O. King to measure the effect in copper.

11. *Thomson's Theory.*—Taking account of the Thomson effect, the thermodynamical theory of the couple was satisfactorily completed by Thomson (*Trans. R. S. Edin.*, 1854). If the quantity of heat absorbed and converted into electrical energy, when unit quantity of electricity (one ampere-second) flows from cold to hot through a difference of temperature, dt, be represented by sdt, the coefficient s is called the specific heat of electricity in the metal, or simply the coefficient of the Thomson effect. Like the Peltier coefficient, it may be measured in joules or calories per ampere-second per degree, or more conveniently and simply in microvolts per degree.

Consider an elementary couple of two metals A and B for which s has the values s' and s'' respectively, with junctions at the temperature T and $T+dT$ (absolute), at which the coefficients of the Peltier effect are P and $P+dP$. Equating the quantity of heat absorbed to the quantity of electrical energy generated, we have by the first law of thermodynamics the relation

$$dE/dT=dP/dT+(s'-s'') \quad . \quad . \quad . \quad (6)$$

If we apply the second law, regarding the couple as a reversible engine, and considering only the reversible effects, we obtain

$$(s'-s'')/T=-d(P/T)/dT \quad . \quad . \quad . \quad (7)$$

Eliminating $(s'-s'')$ we find for the Peltier effect

$$P=TdE/dT=Tp \quad . \quad . \quad . \quad . \quad (8)$$

Whence we obtain for the difference of the specific heats

$$(s'-s'')=-Td^2E/dT^2=-Tdp/dT \quad . \quad . \quad (9)$$

From these relations we observe that the Peltier effect P, and the difference of the Thomson effects $(s'-s'')$, for any two metals are easily deduced from the tabulated values of dE/dt and d^2E/dt^2 respectively. The signs in the above equations are chosen on the assumption that positive electricity flows from cold to hot in the metal s'. The signs of the Peltier and Thomson effects will be the same as the signs of the coefficients given in Table I., if we suppose the metal s' to be lead, and assume that the value of s' may be taken as zero at all temperatures.

12. *Experimental Verification of Thomson's Theory.*—In order to justify the assumption involved in the application of the second law of thermodynamics to the theory of the thermocouple in the manner above specified, it would be necessary and sufficient, as Thomson pointed out (*Phil. Mag.*, December 1852), to make experiments to verify quantitatively the relation $P/T=dE/dT$ between the Peltier effect and the thermoelectric power. A qualitative relation was known at that time to exist, but no absolute measurements of sufficient accuracy had been made. The most accurate measurements of the heat absorption due to the Peltier effect at present available are probably those of H. M. Jahn (*Wied. Ann.*, 34, p. 755, 1888). He enclosed various metallic junctions in a Bunsen ice calorimeter, and observed the evolution of heat per hour with a current of about 1·6 amperes in either direction. The Peltier effect was only a small fraction of the total effect, but could be separated from the Joule effect owing to the reversal of the current. The values of dE/dT for *the same specimens* of metal at 0° C. were determined by experiments between +20° C. and −20° C. The results of his observations are contained in the following table, heat absorbed being reckoned positive as in Table I.:—

Table II.

Thermo-couple.	dE/dT Microvolts per deg.	$P=Td\,E/dT$ Microvolts at 0° C.	Heat calc. Calories per hour.	Heat observed Calories per hour.
Cu-Ag	+2·12	+579	+0·495	+0·413
Cu-Fe	+11·28	+3079	+2·640	+3·163
Cu-Pt	−1·40	−382	−0·327	−0·320
Cu-Zn	+1·51	+412	+0·353	+0·585
Cu-Cd	+2·64	+721	+0·617	+0·616
Cu-Ni	−20·03	−5468	−4·680	−4·362

The agreement between the observed and calculated values in the last two columns is as good as can be expected considering the great difficulty of measuring such small quantities of heat. The analogous reversible heat effects which occur at the junction of a metal and an electrolyte were also investigated by Jahn, but he did not succeed in obtaining so complete an agreement with theory in this case.

13. *Tait's Hypothesis.*—From general considerations concerning minimum dissipation of energy (*Proc. R. S. Edin.*, 1867–68), Tait was led to the conclusion that "the thermal and electric conductivities of metals varied inversely as the absolute temperature, and that the specific heat of electricity was directly proportional to the same." Subsequent experiments led him to doubt this conclusion as regards conductivity, but his thermoelectric experiments (*Proc. R. S. Edin.*, December 1870) appeared to be in good agreement with it. If we adopt this hypothesis, and substitute $s=2cT$, where c is a constant, in the fundamental equation (9), we obtain at once $d^2E/dT^2=-2\ (c'-c'')$, which is immediately integrable, and gives

$$dE/dt=p=2(t_o-t)\ (c'-c'') \quad . \quad . \quad . \quad . \quad (10)$$
$$E_{t-t'}=(t-t')\ (c'-c'')\ \{2t_o-(t+t')\} \quad . \quad . \quad . \quad . \quad (11)$$

where t_o is the temperature of the neutral point at which $dE/dt=0$. This is the equation to a parabola, and is equivalent to the empirical formula of Avenarius, with this difference, that in Tait's formula the constants have all a simple and direct interpretation in relation to the theory. Tait's theory and formula were subsequently assimilated by Avenarius (*Pogg. Ann.*, 149, p. 372, 1873), and are now generally attributed to Avenarius in foreign periodicals.

In accordance with this hypothesis, the curves representing the variations of thermoelectric power, dE/dt, with temperature

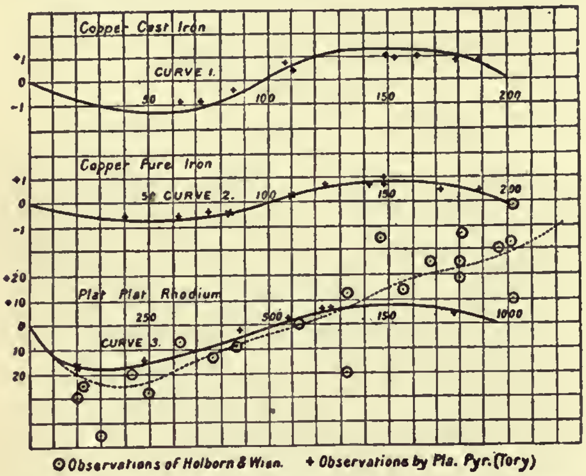

FIG. 2.—Temperature by Thermocouple. Difference from Tait's Formula.

are straight lines, the slope of which for any couple is equal to the difference of the constants $2(c'-c'')$. The diagram constructed by Tait on this principle is fully explained and illustrated in many text-books, and has been generally adopted as embodying in a simple form the fundamental phenomena of thermoelectricity.

14. *Experimental Verification.*—Tait's verification of this hypothesis consisted in showing that the experimental curves of E.M.F. were parabolas in most cases within the limits of error of his observations. He records, however, certain notable divergencies, particularly in the case of iron and nickel, and many others have since come to light from other observations. It should also be remarked that even if the curves were not parabolas, it would always be possible to draw parabolas to agree closely with the observations over a restricted range of temperature. When the question is tested more carefully, either by taking more accurate measurements of temperature, or by extending the observations over a wider range, it is found that there are systematic deviations from the parabola in the majority of cases, which cannot be explained by errors of experiment. A more accurate verification of these relations, both at high and low extremes of temperature, has become possible of late years owing to the development of the theory and application of the platinum resistance thermometer. (See THERMOMETRY.) The curves in fig. 2 illustrate the differences from the parabolic formula, measured in degrees of temperature, as observed by H. M. Tory (*B.A. Report*, 1897). The deviations for the copper-iron couple, and for the copper cast-iron couple over the range 0° to 200° C., appear to be of the order of 1° C., and were carefully verified by repeated and independent series of observations. The deviations of the platinum and platinum-rhodium 10 per cent. couple over the range 0° to 1000° C. are shown on a smaller scale, and are seen to be of a similar nature, but rather greater in proportion. It should be observed that these deviations are continuous, and differ in character from the abrupt changes observed by Tait in special cases. A number of similar deviations at temperatures below 0° C. were found by the writer in reducing the curves representing the observations of Dewar and Fleming (*Phil. Mag.*, July 1895) to the normal scale of temperature from the platinum scale in which they are recorded. In many cases the deviations do not appear to favour any simple hypothesis as to the mode of variation of s with temperature, but as a rule the indication is that s is nearly constant, or even diminishes with rise of temperature. It may be interesting therefore to consider the effect of one or two other simple hypotheses with regard to the mode of variation of s with T.

15. *Other Assumptions.*—If we take the analogy of a perfect gas and assume $s=$constant, we have

$$dE^2/dT^2=-s/T,\ dE/dT=s\log_e T_0/T \quad . \quad . \quad (12)$$
$$E_{(T-T')}=sT\log_e T_0/T-sT''\log_e T_0/T \quad . \quad . \quad (13)$$

where T and T' are the temperatures of the junctions, and T_0 is the neutral temperature. These formulae are not so simple and convenient as Tait's, though apparently founded on a more simple assumption, but they frequently represent the observations more closely. If we suppose that s is not quite constant, but increases or diminishes slightly with change of temperature according to a linear formula $s=s_0+2cT$ (in which s_0 represents the constant part of s, and c may have either sign), we obtain a more general formula which is evidently the sum of the two previous solutions and may be made to cover a greater variety of cases. Another simple and possible assumption is that made by A. Stansfield (*Phil. Mag.*, July 1898), that the value of s varies inversely as the absolute temperature. Putting $s=c/T$, we obtain

$$E_{(T-T')}=c\log_e T/T'-c(T-T')/T_0 \quad . \quad . \quad . \quad (14)$$

which is equivalent to the form given by Stansfield, but with the neutral temperature T_0 explicitly included. According to this formula, the Peltier effect is a linear function of the temperature. It may appear at first sight astonishing that it should be possible to apply so many different assumptions to the solution of one and the same problem. In many cases a formula of the last type would be quite inapplicable, as Stansfield remarks, but the difference between the three is often much less than might be supposed. For instance, in the case of 10 per cent. Rh. Pt.—Pt. couple, if we calculate three formulae of the above types to satisfy the same pair of observations at 0°—445° and 0°—1000° C., we shall find that the formula $s=$constant lies midway between that of Tait and that of Stansfield, but the difference between the formulae is of the same order as that between different observers. In this particular case the parabolic formula appears to be undoubtedly inadequate. The writer's observations agree more nearly with the assumption $s=$constant, those of Stansfield with $s=c/T$. Many other formulae have been suggested. L. F. C. Holborn and A. Day (*Berl. Akad.*, 1899) have gone back to Tait's method at high temperatures, employing arcs of parabolas for limited ranges. But since the parabolic formula is certainly erroneous at low temperatures, it can hardly be trusted for extrapolation above 1000° C.

16. *Absolute Measurement of Thomson Effect.*—Another method of verifying Tait's hypothesis, of greater difficulty but of considerable interest, is to measure the absolute value of the heat absorbed by the Thomson effect, and to observe whether or not it varies with the temperature. Le Roux (*Ann. Chim. Phys.*, x. p. 201, 1867) made a number of relative measurements of the effect in different metals, which agreed qualitatively with observations of the thermoelectric power, and showed that the effect was proportional to the current for a given temperature gradient. Batelli has applied the same method (*Accad. Sci. Turin*, 1886) to the absolute measurement. He observed with a thermocouple the difference of temperature (about ·01° C.) produced by the Thomson effect in twenty minutes between two mercury calorimeters, B_1 and B_2, surrounding the central portions of a pair of rods arranged as in Le Roux's method (see fig. 3). The value of the Thomson

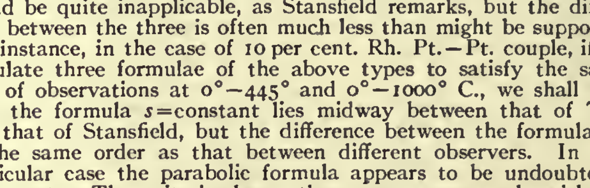

FIG. 3.—Thomson Effect. Batelli (Le Roux's Method).

effect was calculated by multiplying this difference of temperature by the thermal capacity of either calorimeter, and dividing by the current, by the number of seconds in twenty minutes, and by twice the difference of temperature (about 20°) between the ends a and b of either calorimeter. The method appears to be open to the objection that the difference of temperature reached in so long an interval would be more or less independent of the thermal capacities of the calorimeters, and would also be difficult to measure accurately with a thermocouple under the conditions described. The general results of the work appeared to support Tait's hypothesis that the effect was proportional to the absolute temperature, but direct thermoelectric tests do not appear to have been made on the specimens employed, which would have afforded a valuable confirmation by the comparison of the values of d^2E/dT^2, as in Jahn's experiments.

17. *King's Experiments.*—The method employed by the writer, to which allusion has already been made, consisted in observing the change of distribution of temperature in terms of the resistance along a wire heated by an electric current, when the heating current was reversed. It has been fully described by King (*Proc. Amer. Acad.*, June 1898), who applied it most successfully to the case of copper. Although the effect in copper is so small, he succeeded in obtaining changes of temperature due to the Thomson effect of the order of 1° C., which could be measured with satisfactory accuracy. He also determined the effect of change of temperature distribution on the rate of generation of heat by the current; and on the external loss of heat by radiation, convection and conduction. It is necessary to take all these conditions carefully into account in calculating the balance due to the Thomson effect. According to King's experiments, the value of the effect

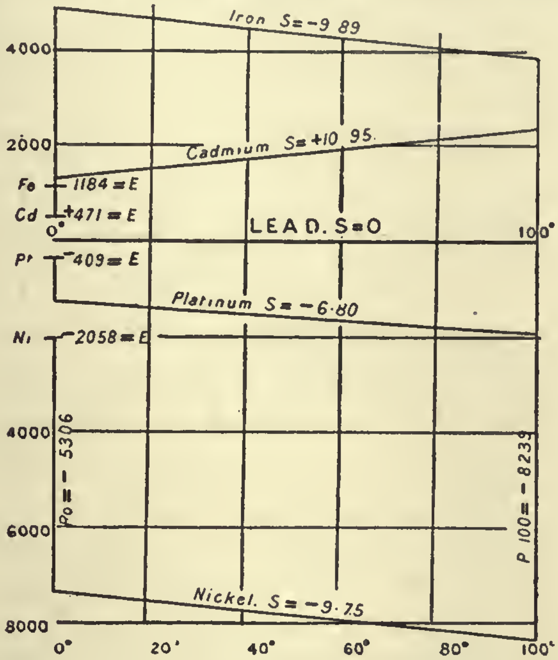

Fig. 4.—Potential Diagrams of Thermocouple on the Contact Theory.

appears to diminish with rise of temperature to a slight extent in copper, but the diminution is so small that he does not regard it as established with certainty. The value found at a temperature of 150° C. was +2·5 microjoules per ampere-second per degree, or +2·5 microvolts per degree in the case of copper, which agrees very fairly with the value deduced from thermoelectric tests. The value found by Batelli for iron was −5·0 microvolts per degree at 108° C., which appears too small in comparison. These measurements, though subject to some uncertainty on account of the great experimental difficulties, are a very valuable confirmation of the accuracy of Thomson's theory, because they show that the magnitude of the effect is of the required order, but they cannot be said to be strongly in support of Tait's hypothesis. A comparison of the results of different observers would also suggest that the law of variation may be different in different metals, although the differences in the values of d^2E/dT^2 may be due in part to differences of purity or errors of observation. It would appear, for instance, according to the observations of Dewar and Fleming, that the value of s for iron is positive below −150° C., at which point it vanishes. At ordinary temperatures the value is negative, increasing rapidly in the negative direction as the temperature rises. This might be appropriately represented, as already suggested, by a linear formula $s=s_0-cT$.

18. *Potential Diagrams on the Contact Theory.*—It is instructive to consider the distribution of potential in a thermoelectric circuit, and its relation to the resultant E.M.F. and to the seat of the E.M.F. In fig. 4, which is given as an illustration, the cold junctions are supposed to be at 0° C. and the hot junctions at 100° C. Noll's values (Table I.) are taken for the E.M.F., and it is supposed that the coefficient of the Thomson effect is zero in lead, *i.e.* that there is no E.M.F. and that the potential is uniform throughout the length of the lead wire. Taking the lead-iron couple as an example, the value of dE/dt at the hot junction 100° C. is 10·305 microvolts per degree, and the value of the Peltier coefficient $P=TdE/dT$ is +3844 microvolts. In other words, we may suppose that there is an E.M.F. of that magnitude situated at the junction which causes positive electricity to flow from the lead to the iron. If the circuit is open, as represented in the diagram, the flow will cease as soon as it has raised the potential of the iron 3844 microvolts above that of the lead. In the substance of the iron itself there is an E.M.F. due to the Thomson effect of about 10 microvolts per degree tending to drive positive electricity from hot to cold, and raising the cold end of the iron 989 microvolts in potential above the hot end on open circuit. At the cold junction the iron is supposed to be connected to a piece of lead at 0° C., and there is a sudden drop of potential due to the Peltier effect of 3648 microvolts. If the circuit is cut at this point, there remains a difference of potential $E=1184$ microvolts, the resultant E.M.F. of the circuit, tending to drive positive electricity from the iron to the lead across the cold junction. If the circuit is closed, there will be a current $C=E/R$, where $R=R'+R''$, the sum of the resistances of the lead and iron. The flow of the current will produce a fall of potential ER'/R in the lead from cold to hot, and ER''/R in the iron from hot to cold, but the potential difference due to the Peltier effect at either junction will not be affected. For simplicity in the diagram the temperature gradient has been taken as uniform, and the specific heat s=constant, but the total P.D. would be the same whatever the gradient.

Similar diagrams are given in fig. 4 for cadmium in which both the specific heat and the Peltier effect are positive, and also for platinum and nickel in which both coefficients are negative. The metals are supposed to be all joined together at the hot junction, and the circuit cut in the lead near the cold junction. The diagram will serve for any selected couple, such as iron-nickel, and is not restricted to combinations with lead. The following table shows the component parts of the E.M.F. in each case:—

Table III.

Thermocouple.	P_{100} —	$-P_0$ —	$-100\times s_{50}$ =	$E_{0\text{-}100}$
Iron-lead .	+3844 −	+3648 −	−988 =	+1184
Cadmium-lead.	+2389 −	+823 −	+1095 =	+471
Platinum-lead .	−1919 −	−828 −	−682 =	−409
Nickel-lead .	−8239 −	−5206 −	−975 =	−2058

The components for any other combination of two are found by taking the algebraic difference of the values with respect to lead.

19. *Relation to the Volta Effect.*—It is now generally conceded that the relatively large differences of potential observable with an electrometer between metals on open circuit, as discovered by Volta, are due to the *chemical* affinities of the metals, and have no direct relation to thermoelectric phenomena or to the Peltier effect. The order of the metals in respect of the two effects is quite different. The potential difference, due to the Volta effect in air, has been shown by Thomson (Lord Kelvin) and his pupils to be of the same order of magnitude, if not absolutely the same, as that produced in a dilute electrolyte in which two metallically connected plates (*e.g.* zinc and copper) are immersed. (On this hypothesis, it may be explained by regarding the air as an electrolyte of infinite specific resistance.) It is also profoundly modified by the state of the exposed surfaces, a coating of oxide on the copper greatly increasing the effect, as it would in a voltaic cell. The Peltier effect and the thermo-E.M.F., on the other hand, do not depend on the state of the surfaces, but only on the state of the substance. An attempt has been made to explain the Volta effect as due to the affinity of the metals *for each other*, but that would not account for the variation of the effect with the state of the surface, except as affecting the actual surface of contact. It is equally evident that chemical affinity between the metals cannot be the explanation of the Peltier E.M.F. This would necessitate chemical action at the junction when a current passed through it, as in an electrolytic cell, whereas the action appears to be purely thermal, and leads to a consistent theory on that hypothesis. The chemical action between metals in the solid state must be infinitesimal, and could only suffice to produce small charges analogous to those of frictional electricity; it could not maintain a permanent difference of potential at a metallic junction through which a current was passing. Although it is possible that differences of potential larger than the Peltier effect might exist between two metals in contact on open circuit, it is certain that the only effective E.M.F. in practice is the

Peltier effect, and that the difference of potential in the substance of the metals when the circuit is complete cannot be greater than the coefficient P. The Peltier effect, it may be objected, measures that part only of the potential difference which depends upon temperature, and can therefore give no information about the absolute potential difference. But the reason for concluding that there is no other effective source of potential difference at the junction besides the Peltier effect, is simply that no other appreciable action takes place at the junction when a current passes except the Peltier generation or absorption of heat.

20. *Convection Theory.*—The idea of convection of heat by an electric current, and the phrase "specific heat of electricity" were introduced by Thomson as a convenient mode of expressing the phenomena of the Thomson effect. He did not intend to imply that electricity really possessed a positive or negative specific heat, but merely that a quantity of heat was absorbed in a metal when unit quantity of electricity flowed from cold to hot through a difference of temperature of 1°. The absorption of heat was considered as representing an equivalent conversion of heat energy into electrical energy in the element. The element might thus be regarded as the seat of an E.M.F., $dE=sdT$, where dT is the difference of temperature between its ends. The potential diagrams already given have been drawn on this assumption, that the Thomson effect is not really due to convection of heat by the current, but is the measure of an E.M.F. located in the substance of the conductor. This view with regard to the seat of the E.M.F. has been generally taken by the majority of writers on the subject. It is not, however, necessarily implied in the reasoning or in the equations given by Thomson, which are not founded on any assumptions with regard to the seat of the E.M.F., but only on the balance of heat absorbed and evolved in all the different parts of the circuit. In fact, the equations themselves are open to an entirely different interpretation in this respect from that which is generally given.

Returning again to the equations already given in § 11 for an elementary thermocouple, we have the following equivalent expressions for the E.M.F. dE, namely,

$$dE=dP+(s'-s'')dT=(P/T)dT=pdT=(p''-p')dT,$$

in which the coefficient, P, of the Peltier effect, and the thermoelectric power, p, of the couple, may be expressed in terms of the difference of the thermoelectric powers, p' and p'', of the separate metals with respect to a neutral standard. So far as these equations are concerned, we might evidently regard the seat of the E.M.F. as located entirely in the conductors themselves, and not at all at the junctions, if p or $(p''-p')$ is the difference of the E.M.F.s per degree in corresponding elements of the two metals. In this case, however, in order to account for the phenomenon of the Peltier effect at the junctions, it is necessary to suppose that there is a *real convection of heat* by an electric current, and that the coefficient P or pT is the difference of the quantities of heat carried by unit quantity of electricity in the two metals. On this hypothesis, if we confine our attention to one of the two metals, say p'', in which the current is supposed to flow from hot to cold, we observe that $p''dT$ expresses the quantity of heat converted into electrical energy per unit of electricity by an E.M.F. p'' per 1° located in the element dT. It happens that the absolute magnitude of p'' cannot be experimentally determined, but this is immaterial, as we are only concerned with differences. The quantity of heat liberated by convection as the current flows from hot to cold is represented in the equation by $dP=d(pT)$. Since $d(p''T)=p''dT+Tdp''$, it is clear that the balance of heat liberated in the element is only $Tdp''=s''dT$, namely, the Thomson effect, and is *not* the equivalent of the E.M.F. $p''dT$, because on this theory the absorption of heat is masked by the convection. If p is constant there is no Thomson effect, but it does not follow that there is no E.M.F. located in the element. The Peltier effect, on the other hand, may be ascribed entirely to convection. The quantity of heat $p''T$ is brought up to one side of the junction per unit of electricity, and the quantity of heat $p'T$ taken away on the other. The balance $(p''-p')T$ is evolved at the junction. If, therefore, we are prepared to admit that an electric current can carry heat, the existence of the Peltier effect is no proof that a corresponding E.M.F. is located at the junction, or, in other words, that the conversion of heat into electrical energy occurs at this point of the circuit, or is due to the contact of dissimilar metals. On the contact theory, as generally adopted, the E.M.F. is due entirely to change of substance $(dP-Tdp)$; on the convection theory, it is due entirely to change of temperature (pdT). But the two expressions are equivalent, and give the same results.

21. *Potential Diagrams on Convection Theory.*—The difference between the two theories is most readily appreciated by drawing the potential diagrams corresponding to the supposed locations of the E.M.F. in each case. The contact theory has been already illustrated in fig. 4. Corresponding diagrams for the same metals on the convection theory are given in fig. 5. In this diagram the metals are supposed to be all joined together and to be at the same time potential at the cold junction at 0° C. The ordinate of the curve at any temperature is the difference of potential between any point in the metal and a point in lead at the same temperature. Since there is no contact E.M.F. on this theory, the ordinates also represent the E.M.F. of a thermocouple metal-

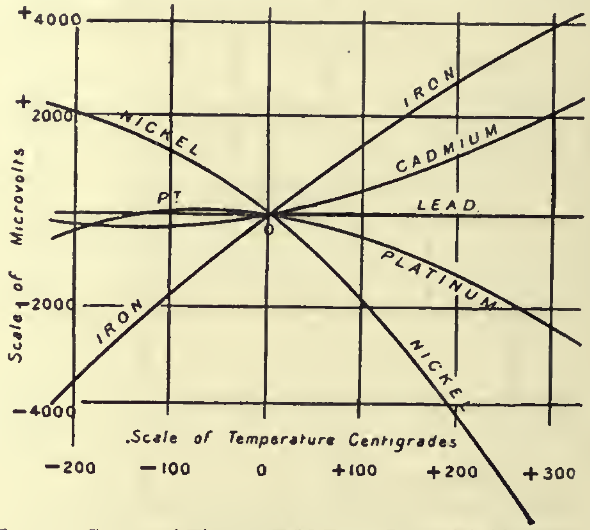

FIG. 5.—Curves of Thermo-E.M.F., or Potential Diagrams, on the Convection Theory.

lead, in which one junction is at 0° C. and the other at t° C. For this reason the potential diagrams on the convection theory are more simple and useful than those on the contact theory. The curves of E.M.F. are in fact the most natural and most convenient method of recording the numerical data, more particularly in cases where they do not admit of being adequately represented by a formula. The line of lead is taken to be horizontal in the diagram, because the thermoelectric power, p, may be reckoned from any convenient zero. It is not intended to imply that there is no E.M.F. in the metal-lead with change of temperature, but that the value of p in this metal is nearly constant, as the Thomson effect is very small. It is very probable that the absolute values of p in different metals are of the same sign and of the same order of magnitude, being large compared with the differences observed. It would be theoretically possible to measure the absolute value in some metal by observing with an electrometer the P.D. between parts of the same metal at different temperatures, but the difference would probably be of the order of only one-hundredth of a volt for a difference of 100° C. It would be sufficiently difficult to detect so small a difference under the best conditions. The difficulty would be greatly increased, if not rendered practically insuperable, by the large difference of temperature.

22. *Conduction Theory.*—In Thomson's theory it is expressly assumed that the reversible thermal effects may be considered separately without reference to conduction. In the conduction theory of F. W. G. Kohlrausch (*Pogg. Ann.*, 1875, vol. 156, p. 601), the fundamental postulate is that the thermo-E.M.F. is due to the conduction of heat in the metal, which is contrary to Thomson's theory. It is assumed that a flow of heat Q, due to conduction, tends to carry with it a proportional electric current $C=aQ$. This is interpreted to mean that there is an E.M.F. $dE=-akr\ dT=-\theta dT$, in each element, where k is the thermal conductivity and

r the specific resistance. The "thermoelectric constant," θ, of Kohlrausch, is evidently the same as the thermoelectric power, p, in Thomson's theory. In order to explain the Peltier effect, Kohlrausch further assumes that an electric current, C, carries a heat-flow, $Q=A\theta C$, with it, where "A is a constant which can be made equal to unity by a proper choice of units." If A and θ are constant, the Peltier effects at the hot and cold junctions are equal and opposite, and may therefore be neglected. The combination of the two postulates leads to a complication. By the second postulate the flow of the current increases the heat-flow, and this by the first postulate increases the E.M.F., or the resistance, which therefore depends on the current. It is difficult to see how this complication can be avoided, unless the first postulate is abandoned, and the heat-flow due to conduction is assumed to be independent of the thermoelectric phenomena. By applying the first law of thermodynamics, Kohlrausch deduces that a quantity of heat, $C\theta dT$, is absorbed in the element dT per second by the current C. He wrongly identifies this with the Thomson effect, by omitting to allow for the heat carried. He does not make any application of the second law to the theory. If we apply Thomson's condition $P=TdE/dT=Tp$, we have $A=T$. If we also assume the ratio of the current to the heat-flow to be the same in both postulates, we have $a=1/T\theta$, whence $\theta^2=kr/T$. This condition was applied in 1899 by C. H. J. B. Liebenow (*Wied. Ann.*, 68, p. 316). It simplifies the theory, and gives a possible relation between the constants, but it does not appear to remove the complication above referred to, which seems to be inseparable from any conduction theory.

L. Boltzmann (*Sitz. Wien. Akad.*, 1887, vol. 96, p. 1258) gives a theoretical discussion of all possible forms of expression for thermoelectric phenomena. Neglecting conduction, all the expressions which he gives are equivalent to the equations of Thomson. Taking conduction into account in the application of the second law of thermodynamics, he proposes to substitute the inequality, $Td/dET-P\leq 2\sqrt{T}(\sqrt{k'r'}+\sqrt{k''r''})$, instead of the equation given by Thomson, namely, $P=TdE/dT$. Since, however, Thomson's equation has been so closely verified by Jahn, it is probable that Boltzmann would now consider that the reversible effects might be treated independently of conduction.

23. *Thermoelectric Relations.*—A number of suggestions have been made as to the possible relations between heat and electricity, and the mechanism by which an electric current might also be a carrier of heat. The simplest is probably that of W. E. Weber (*Wied. Ann.*, 1875), who regarded electricity as consisting of atoms much smaller than those of matter, and supposed that heat was the kinetic energy of these electric atoms. If we suppose that an electric current in a metal is a flow of negative electric atoms in one direction, the positive electricity associated with the far heavier material atoms remaining practically stationary, and if the atomic heat of electricity is of the same order as that of an equivalent quantity of hydrogen or any other element, the heat carried per ampere-second at 0° C., namely P, would be of the order of ·030 of a joule, which would be ample to account for all the observed effects on the convection theory. Others have considered conduction in a metal to be analogous to electrolytic conduction, and the observed effects to be due to "migration of the ions." The majority of these theories are too vague to be profitably discussed in an article like the present, but there can be little doubt that the study of thermoelectricity affords one of the most promising roads to the discovery of the true relations between heat and electricity.

Alphabetical Index of Symbols.

a, b, c = Numerical constants in formulae.
C = Electric Current.
E = E.M.F. = Electromotive Force.
k = Thermal Conductivity.
P = Coefficient of Peltier Effect.
$p = dE/dt$ = Thermoelectric Power.
Q = Heat-flow due to Conduction.
R = Electrical Resistance; r, Specific Resistance.
s = Specific Heat, or Coefficient of Thomson Effect.
t = Temperature on the Centigrade Scale.
T = Temperature on the Absolute Scale.

(H. L. C.)

THERMOMETRY (Gr. θερμός, warm; μέτρον, a measure), the art of measuring temperature or degree of heat. The instruments used for this purpose are known as thermometers, or sometimes, when the temperatures to be measured are high, as pyrometers.

1. A brief sketch of the evolution of the thermometer is included in the article HEAT, §§ 2 and 3. The object of the present article is to discuss the general principles on which the accurate measurement of temperature depends, and to describe the application of these principles to the construction and use of the most important types of thermometer. Special attention will be devoted to more recent advances in scientific methods of testing thermometers and to the application of electrical and optical methods to the difficult problem of measuring high temperatures. In the article PYROMETER an account will be found of some of the thermoscopic methods employed in the arts for determining high temperatures.

2. *Zero: Fundamental Interval.*—In all systems of measuring temperature it is necessary (1) to choose a zero or starting-point from which to reckon, (2) to determine the size of the degree by subdividing the interval between two selected fixed points of the scale (called the "fundamental interval") into a given number of equal parts. The fundamental interval selected is that between the temperature of melting ice and the temperature of condensing steam, under standard atmospheric pressure. On the Centigrade system the fundamental interval is divided into 100 parts, and the melting-point of ice is taken as the zero of the scale. We shall denote temperature reckoned on this system by the letter t, or by affixing the letter C. It is often convenient to reckon temperature, not from the melting-point of ice, but from a theoretical or absolute zero representing the lowest conceivable temperature. We shall denote temperature reckoned in this manner by the letter T, or θ, or by affixing the letters *Abs*. In practice, since the absolute zero is unattainable, the absolute temperature is deduced from the Centigrade temperature by adding a constant quantity, T_0, representing the interval between the absolute zero and the melting-point of ice; thus $T=t+T_0$.

3. *Arbitrary Scales.*—An arbitrary scale can be constructed by selecting any physical property of a substance which varies regularly with the temperature, such as the volume of a liquid, or the pressure or density of a gas, or the electrical resistance of a metal. Thus if V denote the volume of a given mass at the temperature t, and if V_0, V_1 represent the volumes of the same mass at the temperatures 0° and 100° C., the size of 1° C. on the scale of this arbitrary thermometer is one hundredth part of the fundamental interval, namely $(V_1-V_0)/100$, and the temperature t at volume V is the number of these degrees contained in the expansion $V-V_0$ between 0° and t° C. We thus arrive at the formula

$$t=100\ (V-V_0)/(V_1-V_0) \quad . \quad . \quad . \quad (1),$$

which is the general expression for the temperature Centigrade on any such arbitrary scale, provided that we substitute for V the particular physical property selected as the basis of the scale. If we prefer to reckon temperature from an arbitrary zero defined by the vanishing of V, which may conveniently be called the *fundamental zero* of the scale considered, we have, putting V = 0 in equation (1), the numerical values of the fundamental zero T_0, and of the temperature T reckoned from this zero

$$T_0=100V_0/(V_1-V_0), \text{ and } T=T_0V/V_0=t+T_0 \quad . \quad . \quad . \quad (2).$$

It is frequently convenient to measure temperature in this manner when dealing with gases, or electrical resistance thermometers.

4. *Absolute Scale.*—It is necessary for theoretical purposes to reduce all experimental results as far as possible to the absolute scale, defined as explained in HEAT, § 21, on the basis of Carnot's principle, which is independent of the properties of any particular substance. Temperature on this scale measured from the absolute zero will be denoted by the letter θ. This scale can be most nearly realized in practice by observing the temperature T on the scale of a gas-thermometer, and making special experiments on the gas to determine how far its scale deviates from that of the thermodynamical engine. In the case of the gases hydrogen and helium, which can exist in the liquid state only at very low temperatures, the deviations from the absolute scale at ordinary temperatures are so small that

they cannot be certainly determined. Thermometers containing these gases are generally taken as the ultimate standards of reference in practical thermometry.

Mercurial Thermometry

5. The most familiar type of thermometer depends on the apparent expansion of a liquid hermetically sealed in a glass bulb attached to a graduated stem of fine bore. Of all liquid-in-glass thermometers those containing mercury are almost invariably selected for scientific purposes, although at first sight mercury would appear to be the least suitable liquid, on account of its small coefficient of expansion. The smallness of the expansion necessitates an extremely fine bore for the stem, which introduces errors in consequence of the high surface tension of mercury. The considerable density of the liquid also tends to exaggerate the effects of change of position due to variation of the pressure exerted on the interior of the bulb by the liquid column. These errors are small and fairly regular, and can be corrected within certain limits. A much more serious source of trouble, especially at high temperatures, is the imperfect elasticity of the glass, which causes more or less irregular changes in the volume of the bulb. The effect of these changes on the readings of the thermometer is enhanced by the smallness of the expansion of mercury, and might be reduced by employing a more expansible liquid. It is more likely, however, that the defect will be remedied by the construction of thermometers of fused quartz, which is the most perfectly elastic solid hitherto discovered. For work at low temperatures the range of a mercury thermometer is limited by its freezing-point (−39° C.).

These are the serious disadvantages attending the use of mercury, but in other respects it possesses so many advantages over alcohol or other substitutes, that it will in all probability continue to be used almost exclusively in thermometers of this type for scientific work. Among its chief advantages may be reckoned its high boiling-point (357° C.), and the absence of evaporation from the top of the thread, which is so serious a source of error with the alcohol thermometer. With mercury the evaporation is almost inappreciable at 100° C., and can in all cases be avoided by exposing the upper parts of the emergent thread to the temperature of the air. Although an evacuated mercury thermometer cannot be safely used at temperatures over 300° C., owing to the breaking up of the thread of liquid in the stem, it has been found possible, by filling the upper part of the stem with nitrogen or carbon dioxide under high pressure, to extend the range to 550° C. A more important advantage for accurate work is the fact that mercury does not wet glass, and avoids any possible errors due to adherent films of liquid on the walls of the tube. This greatly facilitates observations, and also renders it possible to calibrate the thermometer *after* construction, which cannot be satisfactorily accomplished with other liquids. The process of construction and calibration is further facilitated by the fact that mercury does not dissolve air to any appreciable extent. In consequence of the regularity of expansion of mercury at ordinary temperatures, the scale of the mercury thermometer agrees very closely with that of the gas thermometer. The liquid is very easily obtained in a high state of purity by distillation, and has practically no chemical action on glass. In this respect it is superior to the liquid alloy of potassium and sodium, which has been employed in some high-temperature thermometers, but which rapidly reduces silica at high temperatures. The high conductivity and low specific heat of mercury as compared with most other liquids tend to render the thermometer quick and sensitive in action. Its opacity considerably facilitates accurate reading, and even the smallness of its expansion has one great countervailing advantage, in that the correction for stem-exposure is proportionately reduced. This correction, which (even in the case of mercury) may amount to as much as 40° C. at 550° C., is far the most uncertain in its application, and is the most serious objection to the use of the liquid-in-glass thermometer at high temperatures.

6. *Construction.*—The construction of the most accurate type of mercury thermometer has undergone some changes of detail in recent years. The range of the most accurate standards is generally restricted to the fundamental interval. The length of a degree on the stem can be increased to any extent by enlarging the bulb or diminishing the bore of the stem, but it is found in practice that there is no advantage in making the scale more open than one centimetre to the degree C. in standard instruments, or in increasing the number of divisions beyond ten or at most twenty to the degree. Enlarging the bulb makes the instrument sluggish, and exaggerates the errors due to imperfect elasticity. Diminishing the bore of the tube increases the errors due to capillary friction. Even one centimetre to the degree is an impracticable scale for thermometers graduated continuously from 0° to 100° C., owing to the excessive length of the stem. In order to secure so open a scale, it is necessary to limit the range to 35°, or at most 50°. The fixed points 0° and 100° may still be retained, for purposes of testing and reference, by the device, now commonly employed, of blowing auxiliary bulbs or *ampoules* on the stem, the volume of which is carefully adjusted to correspond with the number of degrees that it is desired to suppress.

In the best instruments for work of precision the bulb is not blown on the capillary tube itself, but is formed of a separate piece of tube fused on the stem. It is possible in this manner to secure greater uniformity of strength and regularity of dimensions. The thickness of the glass is generally between half a millimetre and one millimetre. The advantage in point of quickness gained by making the glass thin is more than counterbalanced by increased fragility and liability to distortion. The best form of bulb is cylindrical, of the same external diameter as the stem. The bore of the stem should also be cylindrical, and not oval or flattened, in order to diminish errors due to capillarity, and to secure the greatest possible uniformity of section. The glass should be clear, and not backed with opal, both to admit of reading from either side, and to minimize risk of bending or distortion. In the commoner sorts of thermometers, which are intended for rough purposes and to be read without the application of minute corrections, it is not unusual to divide the tube into divisions of equal volume by a preliminary calibration. In the most accurate instruments it is preferable to divide the tube into divisions of equal length, as this can be more accurately effected. The corrections to be applied to the readings to allow for inequalities of bore can be most satisfactorily determined in the case of mercury thermometers by calibrating the tube after the instrument is completed (see Calibration). This correction is known as the "calibration correction." Instead of being separately determined it may be included in the scale correction by comparison with a standard instrument, such as a platinum-resistance thermometer.

7. *Corrections.*—The corrections to be applied to the readings of a mercury thermometer, in addition to the calibration correction, may be summarized under the following heads: (i.), Zero. (ii.) Fundamental Interval. (iii.) Internal and External Pressure. (iv.) Stem Exposure. (v.) Scale Correction, including Poggendorff's correction.

(1) The *changes of zero* are of two kinds. (*a*) *Secular rise* of zero due to gradual recovery from changes or strains acquired by the bulb during the process of manufacture. This process may be hastened and subsequent changes practically eliminated by annealing the bulb after manufacture, and before final adjustment, at a high temperature, such as that of boiling sulphur (about 450° C.). A thermometer which has not been so treated may show a rise of zero amounting to as much as 20° or 30° when exposed for some time to a temperature of 350° C. (*b*) *Temporary depression* of zero after each exposure to a high temperature, followed by a slow recovery which may last for days or weeks. The best thermometers of hard glass show a depression of zero amounting to about one-tenth of 1° C. after exposure to 100° C. In softer glass the depression is usually greater and more persistent, and may amount to half a degree after 100° C. At higher temperatures the depression generally increases roughly as the square of the temperature above 0° C. It may amount to 2° or 3° at 300° C. The effect cannot be calculated or predicted in any series of observations,

because it depends in so complicated a manner on the past history and on the time. It is a most serious difficulty in accurate mercurial thermometry, especially at high temperatures. The most satisfactory method of correction appears to be to observe the zero *immediately after each reading*, and to reckon the temperature from the variable zero thus observed. The rationale of this procedure is that the depression is produced at the high temperature much more rapidly than the subsequent recovery at the low temperature. The thermometer is taken from the bath and allowed to cool rapidly by free exposure to the air. As soon as it reaches 40° or 50° C., it is plunged in the melting ice, and the lowest point reached is taken as the temporary zero.

The following formulae have been proposed by various observers to represent the depression of zero for different kinds of glass:—

$$\left.\begin{array}{l}\text{Pernet, French } \textit{cristal},\ dz=0{\cdot}0040(t/100)^2 \\ \text{Guillaume, } \textit{Verre dur},\ 0-100^\circ\text{ C.},\ dz=(8886t+10{\cdot}84t^2)\,10^{-7} \\ \text{Bottcher, } \textit{Cristal dur},\ 0-190^\circ\text{ C.},\ dz=(7970t+329t^2)10^{-7} \\ \quad\text{,, Jena, 16, iii., } dz=(7100t-8t^2)\,10^{-7}\end{array}\right\} \quad (4)$$

The symbol dz in these formulae stands for the depression of zero produced by an exposure to a temperature t. The depression is about three times as large in French crystal as in English flint glass, and varies roughly as the square of t. *Verre dur* and Jena, 16, iii., are varieties of hard glass chosen as standards in France and Germany respectively, on account of the comparatively small depression of zero to which they are liable. At low temperatures, up to 50° C., the depression is very nearly proportional to t, but at temperatures above 100° C. it is necessary to adopt another formula in which the term depending upon t^2 is more important. These formulae are useful as giving an idea of the probable size of the correction in any case, but they cannot be employed in practice except in the simplest cases and at low temperatures. On account of these temporary changes of zero, a mercury thermometer intended for the most accurate work at ordinary temperatures (as in calorimetry) should preferably never be heated above 40° or 50° C., and certainly never above 100° C. Above 100° C. the changes of zero become more irregular and more variable, depending on the rate of cooling and on the sequence of previous observations, so that even if the method of observing the zero after each reading is adopted, the order of precision attainable rapidly diminishes.

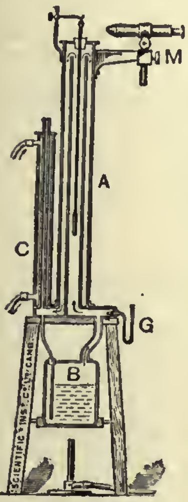

FIG. 1.—Hypsometer.

(II) *Fundamental Interval.*—The thermometer to be tested is exposed to steam condensing at atmospheric pressure in an apparatus which is often called a "hypsometer," constructed with double walls to protect the inner tube containing the thermometer from any cooling by radiation. The standard atmospheric pressure at which the temperature of the steam is by definition equal to 100° C. is equivalent to that produced by a column of mercury at 0° C. and 760 millimetres high, the force of gravitation being equal to that at sea-level in latitude 45°. The atmospheric pressure at the time of observation is reduced to these units by applying the usual corrections for temperature and gravitation. If the pressure is near 760 mm., the temperature of the steam may be deduced by assuming that it increases at the rate of 1° C. for 27·2 mm. of pressure. If the pressure is not near 760 mm., the application of the correction is less certain, but is generally taken from Regnault's tables, from which the following data are extracted. Thermometers cannot be satisfactorily tested at an elevated station where the height of the barometer H is less than 700 mm., as the steam point is too uncertain.

A convenient type of hypsometer is shown in fig. 1. The boiler B is separate from the steam-jacket A surrounding the thermometer. A gauge G is provided for indicating the steam pressure (difference from atmospheric) and a condenser C for returning the condensed steam to the boiler. The thermometer is observed by the microscope M.

steam point. If n be the interval in degrees of the scale between the two observations, and if t_1 be the temperature of the steam, the fundamental interval of the thermometer may be taken as $100\ n/t_1$, provided that t_1 is nearly 100° C. Since all the readings of a thermometer have to be corrected for the error of the fundamental interval, by dividing by the fundamental interval thus observed and multiplying by 100, it is a matter of some convenience in practice to have the instrument graduated so that the difference between the readings in ice and at 100° C. is very nearly 100° of the stem. The correction can then be applied as a small percentage independently of the other corrections. The method of determining the fundamental interval above described applies to all other kinds of thermometers, except that it is not generally necessary to observe the zero *after* the steam point. The temperature of the steam t_1 should be expressed in the scale of the thermometer tested, if the scale differs appreciably from that of Regnault.

(III) *Pressure Correction.*—The corrections for variations of internal and external pressure on the bulb are of some importance in accurate thermometry, but can be applied with considerable certainty at moderate temperatures. The correction for external pressure is assumed to be proportional to the change of pressure, and to be independent of the temperature. It is generally determined by enclosing the thermometer to be tested in a vessel of water, and observing the change of reading on exhausting or readmitting the air. The correction is generally between one and two thousandths of a degree per centimetre of mercury change of pressure, but must be determined for each thermometer, as it depends on the nature of the glass and on the form and thickness of the walls of the bulb. The coefficient of the correction for internal pressure is greater than that for external pressure by the difference between the compressibility of mercury and that of glass, and may be calculated from it by assuming this relation. If b_0, b_1, are the external and internal coefficients, expressed in degrees of temperature per centimetre of mercury, we have the relation

$$b_1=b_0+0{\cdot}00015,\ \text{degrees per cm. of mercury} \quad . \quad . \quad (6)$$

The coefficient of internal pressure can also be determined by taking readings in the horizontal and vertical positions when the thermometer is at some steady temperature such as that of ice or steam. The reading of the thermometer is generally reduced to an external pressure of one standard atmosphere, and to an internal pressure corresponding to the horizontal position. It is also possible to include the internal pressure correction in the scale correction, if the thermometer is always read in the vertical position. In addition to the variations of internal pressure due to the column of mercury in the stem, there are variations due to capillarity. The internal pressure is greater when the mercury is rising than when it is falling, and the reading is depressed to an extent depending on the fineness of the bore and the thinness of the walls of the bulb. The capillary pressure does not depend only on the bore of the tube, but also apparently to an even greater extent on the state of the walls of the tube. The least trace of dirt on the glass or on the mercury is capable of producing capillary pressures much greater than would be calculated from the diameter of the tube. Even in the best thermometers, when there are no inequalities of bore sufficient to account for the observed variations, it is seldom found that the mercury runs equally easily in all parts of the stem. These variations of capillary pressure are somewhat capricious, and set a limit to the order of accuracy attainable with the mercury thermometer. It appears that the difference of reading of a good thermometer between a rising and falling meniscus may amount to five or ten thousandths of a degree. The difference may be reduced by continuous tapping, but it is generally best to take readings always on a rising column, especially as the variations in the angle of contact, and therefore in the capillary pressure, appear to be much smaller for the rising meniscus. In ordinary work the zero reading and the steam reading would both generally correspond to a falling meniscus; the former necessarily, the latter on account of the phenomenon of the temporary depression of zero, which causes the thermometer to read higher during the first moments of its exposure to steam than it does when the expansion of the bulb has reached its limit. It is easy to secure a rising meniscus at the steam point by momentarily cooling the thermometer. At the zero point the meniscus generally begins to rise

TABLE I.—*Temperature of Steam at pressures from 790 to 710 mm.*

Pressure (corrected) . . .	790	780	770	760	750	740	730	720	710
Steam temp. = 100° C.+ . .	+1·083	+·726	+·365	0	−·369	−·742	−1·120	−1·502	−1·888

$$\text{Approximate formula } dt_1=\cdot0367(\text{H}-760)-\cdot000020(\text{H}-760)^2 \quad (5)$$

If the barometer has a brass scale correct at 0° C., and H be the reading in millimetres, the correction for temperature is made approximately by subtracting 0·00163 H mm.

If L is the latitude and M the height of the station in metres above the sea-level, the correction for gravitation is approximately made by subtracting (0·0026 cos 2L+0·0000002M) H mm.

The zero of the thermometer is observed immediately after the after five or ten minutes. The question, however, is not of much importance, as the error, if any, is regular, and the correction for capillarity is necessarily uncertain.

(IV) *Stem-Exposure Correction.*—When the bulb of a mercury thermometer is immersed in a bath at a temperature t, and a part of the column of mercury having a length of n degrees is exposed to a lower temperature t_2, the reading of the thermometer will be lower by $a \times n \times (t-t_2)$ degrees (nearly) than it would have been if the whole of the mercury and stem had been at the temperature t. The factor a in this expression is the apparent coefficient of expansion of mercury in glass, and varies from ·000150 to ·000165 for different kinds of glass. In order to apply this correction, it is usual to observe t_2 by means of an auxiliary "stem-thermometer" with its bulb placed near the middle of the emergent column n. Occasionally stem-thermometers with long thin bulbs are employed to give more nearly the average temperature of the whole emergent column. Owing to conduction along the stem of the thermometer, and to heated vapours near the bath, the mean temperature determined in this manner is generally too low. To allow for this empirically, an arbitrary reduction is often made in the value taken for n or a, but this cannot be regarded as satisfactory for work of precision. The only practical method of reducing the correction is to limit the number of degrees n exposed, or, in other words, to work with thermometers of "limited range." Each of these thermometers must then be corrected by comparison with a standard thermometer free from stem-exposure correction, such as a platinum-resistance thermometer. To secure results of any value the correction must be determined at each point under the actual conditions of observation under which the thermometer is to be used. In work of precision it is necessary to use ten or twenty thermometers to cover a range of 300°, as this is the only method of securing an open scale and reasonable accuracy as regards stem-exposure. To quote the opinion of C. E. Guillaume, one of the leading authorities on mercurial thermometry: "When this correction is large, it cannot generally be determined with sufficient approximation for measurements of precision. The mercury thermometer should then be replaced by other instruments, among which those based on the variation of the electrical resistance of metals hold the first rank."

(V) *Scale Correction.*—The correction required to reduce the readings of a mercurial thermometer to the normal scale may appropriately be called the "scale correction." One of the chief advantages of the mercurial thermometer for scientific purposes is that its scale agrees very closely with the thermodynamical scale between 0° and 200° C. The scale corrections of the standard French thermometers of *verre dur* have been very carefully determined over the range 0° to 80° C. by P. Chappuis using a constant-volume gas thermometer containing hydrogen (at an initial pressure of one metre of mercury at 0° C.) as the representative of the normal scale. His observations between 0° and 80° C. are represented by the quartic equation

$$t_h - t_m = t(t-100)\ (-61{\cdot}859 + 0{\cdot}47351\ t - 0{\cdot}0011577\ t^2) \times 10^{-6}, \quad (7)$$

in which t_h and t_m represent temperature on the scales of the hydrogen and mercury thermometers respectively. The *verre dur* mercury thermometer reads 0·112° C. above the hydrogen thermometer at 40° C. where the difference of the scales is a maximum. The scale corrections of the Jena-glass thermometers, deduced by comparison with the French *verre dur*, appear to be practically of the same magnitude, but show differences of as much as 0·010° C. on either side of the mean. It may be questioned whether it is possible to construct mercury thermometers with scales agreeing more closely than this, owing to inevitable variations in the quality and treatment of the glass. According to Guillaume, the scale of a French *cristal* thermometer t_c differs from that of the standard *verre dur* t_m between 0° and 50° C., according to the cubic formula

$$t_c - t_m = t(100-t)(14{\cdot}126 - 0{\cdot}0311t) \times 10^{-6} \quad . \quad . \quad (8)$$

According to some unpublished observations made by the writer in 1893–1894, the scale of an English flint-glass thermometer, tested by comparison with a platinum thermometer, does not differ from that of the constant-pressure air thermometer by more than one or two hundredths of a degree between 0° and 100° C. But for the comparison of the scales to be of any value, it would be necessary to study a large number of such thermometers. It is possible to obtain much more consistent results if the thermometers are not heated above 50° C.

The comparisons of the *verre dur* thermometers with the normal scale at the International Bureau at Paris have not as yet extended beyond 100° C. The most important observations on the mercury thermometer above these limits appear to be those of Regnault. The later observations of J. M. Crafts were confined to French thermometers of *cristal dur* (*Comptes Rendus*, 1882, 95, p. 863). He found the following deviations from the hydrogen scale:—

t_h	150°	170°	200°	230°	250°	280°	300°	330°
$t_h - t_m$	+·25	+·35	+·27	−·02	−·26	−·63	−1·21	−2·48

The correction changes sign at about 230° C., owing to the rapid increase in the expansion of mercury. Between 0° and 150° C. it would appear that the coefficient of expansion of glass increases more rapidly than that of mercury.

Poggendorff's Correction.—It should be observed that, since in the construction of a mercury thermometer the tube is divided or calibrated so as to read in divisions of equal volume when the whole of the tube is at one temperature, the degrees do not as a matter of fact correspond to equal increments of the apparent expansion of mercury. The scale does not therefore agree in practice with the theoretical formula (1) for the scale of the expansion of mercury, since the expansion is measured in a tube which itself is expanding. A similar argument applies to the method of the weight thermometer, in which the overflow is measured by weight. Even if the expansion of mercury and glass were both uniform, as measured on the thermodynamical scale, the scale of the mercury thermometer, as ordinarily calibrated, would not agree with the thermodynamical scale. The difference can be easily calculated if the actual expansion of mercury and glass is known. The correction is known as Poggendorff's, but is generally included in the scale correction, and is not applied separately. It has the effect of making the thermometer read higher at temperatures between 0° and 100° than it would if the divisions of the stem did

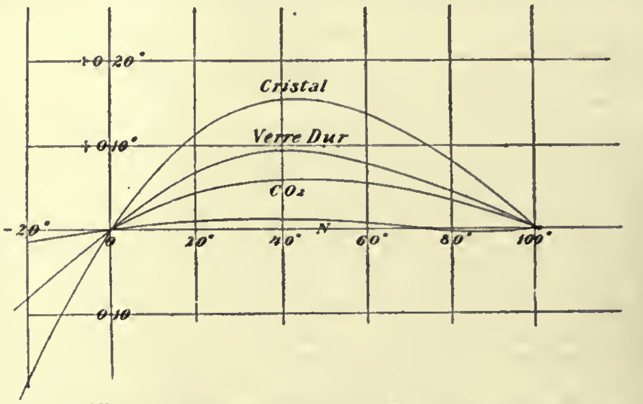

FIG. 2.—Differences between Scales of Mercury, and Gas Thermometers and Hydrogen Scale, according to Guillaume and Chappuis.

not expand as the temperature rose. The amount of the correction for *verre dur* is given by Guillaume as

$$\text{P.C.} = t(100-t)(23{\cdot}920 + 0{\cdot}0240t) \times 10^{-6} \quad . \quad . \quad (9)$$

The value of this correction is between ·060° and ·080° at 50° C. for different thermometers.

GAS THERMOMETRY

8. The deviations of the gas thermometer from the absolute scale are so small that this instrument is now universally regarded as the ultimate standard in thermometry. It had, in fact, already been adopted for this purpose by Regnault and others, on a priori considerations, before the absolute scale itself had been invented. Although the indications of a gas thermometer are not absolutely independent of the changes of volume of the envelope or bulb in which the gas is contained, the effect of any uncertainty in this respect is minimized by the relatively large expansibility of the gas. The capricious changes of volume of the bulb, which are so great a difficulty in mercurial thermometry, are twenty times less important in the case of the gas thermometer. As additional reasons for the choice we have the great simplicity of the laws of gases, and the approximate equality of expansion and close agreement of the thermometric scales of all gases, provided that they are above their critical temperatures. Subject to this condition, at moderate pressures and provided that they are not dissociated or decomposed, all gases satisfy approximately the laws of Boyle and Charles. These two laws are combined in the characteristic equation of the gaseous state, viz., $pv = \text{R}T$, in which p is the pressure and v the volume of unit mass of the gas in question, and R is a constant which varies inversely as the molecular weight of the gas, and is approximately equal to the difference of the specific heats.

9. *Practical Conditions.*—In practice it is not convenient to deal with unit mass, but with an arbitrary mass M occupying a space V, so that the specific volume $v = \text{V/M}$. It is also necessary to measure the pressure p in terms of mercury columns, and not in absolute units. The numerical value of the constant R is adjusted to suit these conditions, but is of no consequence in thermometry, as we are concerned with ratios and differences only. The equation may be written in the form $\text{T} = p\text{V/RM}$, but in order to satisfy the essential condition that T shall be a definite function of the temperature in the case of a gas which does not satisfy Boyle's law exactly, it is necessary to limit

the application of the equation to special cases which lead to definite, but not necessarily identical, thermometric scales. There are three special cases of practical importance, corresponding to three essentially distinct experimental methods.

(i.) *Volumetric Method* (constant-pressure).—In this method V is variable and p and M are constant. This method was employed by Gay-Lussac, and is typified in the ideal thermometer with reservoir of variable capacity designed by Lord Kelvin (*Ency. Brit.*, ed. ix., vol. xi. p. 575, fig. 10). It corresponds to the method ordinarily employed in the common liquid-in-glass thermometer, but is not satisfactory in practice, owing to the difficulty of making a bulb of variable and measurable volume the whole of which can be exposed to the temperature to be measured.

(ii.) *Manometric Method* (constant-volume or density).—In this method p is variable and V and M are constant. Variations of temperature are observed and measured by observing the corresponding variations of pressure with a mercury manometer, keeping a constant mass, M, of gas enclosed in a volume, V, which is constant except for the unavoidable but small expansion of the material of which the bulb is made.

(iii.) *Gravimetric Method* (constant-pressure).—In this method M is variable and p and V are constant. This method is generally confounded with (i.) under the name of the constant-pressure method, but it really corresponds to the method of the weight thermometer, or the "overflow" method, and is quite distinct from an experimental standpoint, although it leads to the same thermometric scale. In applying this method, the weight M of the vapour itself may be measured, as in Regnault's mercury-vapour thermometer, or in Deville and Troost's iodine-vapour thermometer. The best method of measuring the overflow is that of weighing mercury displaced by the gas. The mass of the overflow may also be estimated by observing its volume in a graduated tube, but this method is much less accurate.

In addition to the above, there are mixed methods in which both p and V or M are variable, such as those employed by Rudberg or Becquerel; but these are unsatisfactory for precision, as not leading to a sufficiently definite thermometric scale. There is also a variation of the constant-volume method (ii.), in which the pressure is measured by the volumetric compression of an equal mass of gas kept at a constant temperature, instead of by a manometer. This method is experimentally similar to (iii.), and gives the same equations, but a different thermometric scale from either (ii.) or (iii.). It will be considered with method (iii.), as the apparatus required is the same, and it is useful for testing the theory of the instrument. We shall consider in detail methods (ii.) and (iii.) only, as they are the most important for accurate work.

10. *Construction of Apparatus.*—The manometric or constant-volume method was selected by Regnault as the standard, and has been most generally adopted since his time. His apparatus has not been modified except in points of detail. A description of his instrument will be found in most text-books on heat.

A simple and convenient form of the instrument for general use is Jolly's (described in Poggendorff's *Jubelband*, p. 82, 1874), and represented in fig. 3. The two vertical tubes of the manometer are connected by an india-rubber tube properly strengthened by a cotton covering, and they can be made to slide vertically up and down a wooden pillar which supports them; they are provided with clamps for fixing them in any position and a tangent screw for fine adjustment. The connexion between the bulb and the manometer is made by means of a three-way tap. The scale of the instrument is engraved on the back of a strip of plane mirror before silvering, and the divisions are carried sufficiently far across the scale for the reflections of the two surfaces of the mercury to be visible behind the scale. Parallax can thus be avoided and an accurate reading obtained without the necessity of using a cathetometer. In order to allow for the expansion of the glass of the reservoir a weight-thermometer bulb is supplied with the instrument, made from another specimen of the same kind of glass, and the relative expansion of the mercury and the glass can thus be determined by the observer himself. The volume of the air-bulb and that of the capillary tube and the small portion of the manometer tube above the small beak of glass, the point of which serves as the fiducial mark, are determined by the instrument-makers. The improvements introduced by Chappuis, of the International Bureau at Sèvres, in the construction of the constant-volume hydrogen thermometer selected by the committee for the determination of the normal scale, are described in the text-books (*e.g.* Watson's *Physics*). The most important is the combination of the manometer and the barometer into a single instrument with a single scale, thus reducing the number of readings required. The level of the mercury in the branch of the manometer communicating with the bulb of the gas thermometer is adjusted in the usual manner up to a fixed contact-point, so as to reduce the contained gas to a constant volume. Simultaneously the barometer branch of the manometer is adjusted so that the surface of the mercury makes contact with another point fixed in the upper end of the barometer tube. The distance between the two contact-points, giving the pressure of the gas in the thermometer, is deduced from the reading of a vernier fixed relatively to the upper contact-point. This method of reading the pressure is probably more accurate than the method of the cathetometer which is usually employed, but has the disadvantage of requiring a double adjustment.

FIG. 3.

11. *Pressure Correction.*—In the practical application of the manometric method there are certain corrections peculiar to the method, of which account must be taken in work of precision. The volume of the bulb is not accurately constant, but varies with change of pressure and temperature. The thermal expansion of the bulb is common to all methods, and will be considered in detail later. The pressure correction is small, and is determined in the same manner as for a mercury thermometer. The value so determined, however, does not apply strictly except at the temperature to which it refers. If the pressure-coefficient were constant at all temperatures and equal to e, the pressure correction, dt, at any point t of the scale would be obtainable from the simple formula

$$dt = ep_0t(t-100)/T_0 \quad . \quad . \quad . \quad . \quad (10)$$

where p_0 is the initial pressure at the temperature T_0. But as the coefficient probably varies in an unknown manner, the correction is somewhat uncertain, especially at high temperatures. Another very necessary but somewhat troublesome correction is the reduction of the manometer readings to allow for the varying temperatures of the mercury and scale. Since it is generally impracticable to immerse the manometer in a liquid bath to secure certainty and uniformity of temperature, the temperature must be estimated from the readings of mercury thermometers suspended in mercury tubes or in the air near the manometer. It is therefore necessary to work in a room specially designed to secure great constancy of temperature, and to screen the manometer with the utmost care from the source of heat in measurements of high temperature. Regnault considered that the limit of accuracy of correction was one-tenth of a millimetre of mercury, but it is probably possible to measure to one-hundredth as a mean of several readings under the best conditions, at ordinary temperatures.

12. *Stem-Exposure.*—In all gas thermometers it is necessary in practice that the part of the gas in contact with the mercury or other liquid in the manometer should not be heated, but kept at a nearly constant temperature. The space above the mercury, together with the exposed portion of the capillary tube connecting the manometer with the thermometric bulb, may be called the "dead space." If the volume of the dead space is kept as nearly as possible constant by adjusting the mercury always up to a fixed mark, the quantity of air in this space varies nearly in direct proportion to the pressure, *i.e.* in proportion to the temperature of the thermometric bulb

at constant volume. This necessitates the application of a stem-exposure correction, the value of which is approximately given by the formula

$$dt = rt(t-100)/T_2, \quad . \quad . \quad . \quad . \quad (11)$$

where r is the ratio of the volume of the dead space to the volume of the thermometric bulb, and T_2 is the mean temperature of the dead space, which is supposed to be constant. The magnitude of the correction is proportional to the ratio r, and increases very rapidly at high temperatures. If the dead space is 1 per cent. of the bulb, the correction will amount to only one-tenth of a degree at 50° C., but reaches 5° at 445° C., and 30° at 1000° C. It is for this reason important in high-temperature work to keep the dead space as small as possible and to know its volume accurately. With a mercury manometer, the volume is liable to a slight uncertainty on account of changes of shape in the meniscus, as it is necessary to use a wide tube in order to secure accurate measurements of pressure.

13. *Compensation Method with Oil-Gauge.*—It is possible to avoid this difficulty, and to make the dead space very small, by employing oil or sulphuric acid or other non-volatile liquid to confine the gas in place of mercury (*Phil. Trans.*, A. 1887, p. 171). The employment of a liquid which wets the tube makes it possible to use a much smaller bore, and also greatly facilitates the reading of small changes of pressure. At the same time the instrument may be arranged so that the dead space correction is automatically eliminated with much greater accuracy than it can be calculated. This is effected as shown diagrammatically in fig. 4, by placing side by side with the tube AB, connecting the bulb B to the manometer A, an exact duplicate CD, closed at the end D, and containing liquid in the limb C, which is of the same size as the branch A of the manometer and in direct communication with it. The tube CD, which is called the compensating tube, contains a constant mass of gas under exactly similar conditions of volume and temperature to the tube AB. If therefore the level of the liquid is always adjusted to be the same in both tubes AB and CD, the mass of gas contained in the dead space AB will also be constant, and is automatically eliminated from the equations, as they contain differences only.

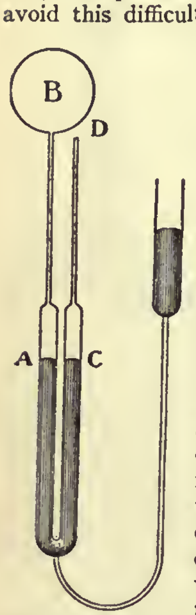

FIG. 4.—Method of Compensation.

14. *Gravimetric Method.*—In the writer's opinion, the gravimetric or overflow method, although it has seldom been adopted, and is not generally regarded as the most accurate, is much to be preferred to the manometric method, especially for work at high temperatures. It is free from the uncertain corrections above enumerated as being peculiar to the manometric method. The apparatus is much simpler to manipulate and less costly to construct. If the pressure is kept constant and equal to the external atmospheric pressure, there is no strain of the bulb, which is particularly important at high temperatures. There is no dead space correction so long as the temperature of the dead space is kept constant. The troublesome operation of reading and adjusting the mercury columns of the manometer is replaced by the simpler and more accurate operation of weighing the mercury displaced, which can be performed at leisure. The uncertain correction for the temperature of the mercury in the manometer is entirely avoided.

The reasons which led Regnault to prefer the constant-volume thermometer are frequently quoted, and are generally accepted as entirely conclusive, but it is very easy to construct the constant-pressure or gravimetric instrument in such a manner as to escape the objections which he urges against it. Briefly stated, his objections are as follows: (1) Any error in the observation of the temperature of the gas in the overflow space produces a considerable error in the temperature deduced, when the volume of the overflow is large. This source of error is very simply avoided by keeping the whole of the overflow in melting ice, an expedient which also considerably simplifies the equations. It happened that Regnault's form of thermometer could not be treated in this manner, because he had to observe the level of the mercury in order to measure the pressure and the volume. It is much better, however, to use a separate gauge, containing oil or sulphuric acid, for observing small changes of pressure. The use of ice also eliminates the correction for the variation of density of the mercury by which the overflow is measured. (2) Regnault's second objection was that an error in the measurement of the pressure, or in reading the barometer, was more serious at high temperatures in the case of the constant-pressure thermometer than in the constant-volume method. Owing to the incessant variations in the pressure of the atmosphere, and in the temperature of the mercury columns, he did not feel able to rely on the pressure readings (depending on observations of four mercury surfaces with the cathetometer) to less than a tenth of a millimetre of mercury, which experience showed to be about the limit of accuracy of his observations. This would be equivalent to an error of 0·036° with the constant-volume thermometer at any point of the scale, but with the constant-pressure thermometer the error would be larger at higher temperatures, since the pressure does not increase in proportion to the temperature. This objection is really unsound, because the ideal condition to be aimed at is to keep the *proportionate error* dT/T constant. That the proportionate error diminishes with rise of temperature, in the case of the constant-volume thermometer, is really of no advantage, because we can never hope to be able to measure high temperatures with greater proportionate accuracy than ordinary temperatures. The great increase of pressure at high temperatures in the manometric method is really a serious disadvantage, because it becomes necessary to work with much lower initial pressures, which implies inferior accuracy at ordinary temperatures and in the determination of the initial pressure and the fundamental interval.

15. *Compensated Differential Gas Thermometer.*—The chief advantage of the gravimetric method, which Regnault and others appear to have missed, is that it is possible to make the measurements altogether independent of the atmospheric pressure and of the observation of mercury columns. This is accomplished by using, as a standard of constant pressure, a bulb S, fig. 5, containing a constant mass of gas in melting ice, side by side with the bulb M, in which the volume of the overflow is measured. The pressure in the thermometric bulb T is adjusted to equality with the standard by means of a delicate oil-gauge G of small bore, in which the difference of pressure is observed by means of a cathetometer microscope. This kind of gauge permits the rapid observation of small changes of pressure, and is far more accurate and delicate than the mercury manometer. The fundamental measurement of the volume of the overflow in terms of the weight of mercury displaced at 0° C. involves a single weighing made at leisure, and requires no temperature correction. The accuracy obtainable at ordinary temperatures in this measurement is about ten times as great as that attainable under the best conditions with the mercury manometer. At higher temperatures the relative accuracy diminishes in proportion to the absolute temperature, or the error dt increases according to the formula

$$dt/t = -(T/T_0)\, dw/w, \quad . \quad . \quad . \quad . \quad (12)$$

where w is the weight of the overflow and dw the error. This diminution of the sensitiveness of the method at high temperatures is commonly urged as a serious objection to the method, but the objection is really without weight in practice, as the possible accuracy of measurement is limited by other conditions. So far as the weighing alone is concerned, the method is sensitive to one-hundredth of a degree at 1000° C., which is far beyond the order of accuracy attainable in the application of the other corrections.

16. *Method of Using the Instrument.*—A form of gas thermometer constructed on the principles above laid down, with the

addition of a duplicate set of connecting tubes C for the elimination of the stem-exposure correction by the method of automatic compensation already explained, is shown in fig. 5 (*Proc. R. S.* vol. 50, p. 243; Preston's *Heat*, p. 133).

In setting up the instrument, after cleaning, and drying and calibrating the bulbs and connecting tubes, the masses of gas on the two sides are adjusted as nearly as possible to equality, in order that any changes of temperature in the two sets of connecting tubes may compensate each other. This is effected with all the bulbs in melting ice, by adjusting the quantities of mercury in the bulbs M and S and equalizing the pressures. The bulb T is then heated in steam to determine the fundamental interval. A weight w_1 of mercury is removed from the overflow bulb M in order to equalize the pressures again. If W is the weight of the mercury at 0° C. which would be required to fill the bulb T at 0° C., and if $W+dW_1$ is the weight of mercury at 0° which would be required to fill a volume equal to that of the bulb in steam at t_1, we have the following equation for determining the coefficient of expansion a, or the fundamental zero T_0,

$$at_1 = t_1/T_0 = (w_1+dW_1)/(W-w_1), \quad . \quad . \quad . \quad (13)$$

Similarly if w is the overflow when the bulb is at any other temperature t, and the expansion of the bulb is dW, we have a precisely similar equation for determining t in terms of T_0, but with t and w and dW substituted for t_1 and w_1 and dW_1. In practice, if the pressures are not adjusted to exact equality, or if the volumes of

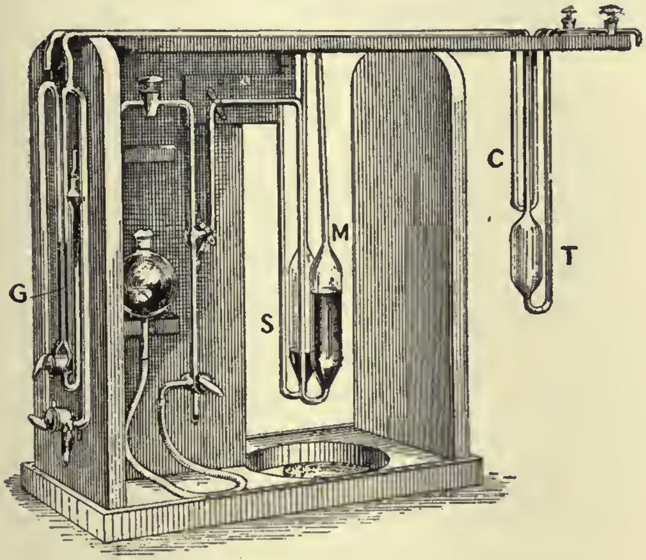

FIG. 5.—Compensated Differential Gas Thermometer.

the connecting tubes do not exactly compensate, it is only necessary to include in w a small correction dw, equivalent to the observed difference, which need never exceed one part in ten thousand.

It is possible to employ the same apparatus at constant volume as well as at constant pressure, but the manipulation is not quite so simple, in consequence of the change of pressure. Instead of removing mercury from the overflow bulb M in connexion with the thermometric bulb, mercury is introduced from a higher level into the standard bulb S so as to raise its pressure to equality with that of T at constant volume. The equations of this method are precisely the same as those already given, except that w now signifies the "inflow" weight introduced into the bulb S, instead of the overflow weight from M. It is necessary, however, to take account of the pressure-coefficient of the bulb T, and it is much more important to have the masses of gas on the two sides of the apparatus equal than in the other case. The thermometric scale obtained in this method differs slightly from the scale of the manometric method, on account of the deviation of the gas compressed at 0° C. from Boyle's law, but it is easy to take account of this with certainty.

Another use to which the same apparatus may be put is the accurate comparison of the scales of two different gases at constant volume by a differential method. It is usual to effect this comparison indirectly, by comparing the gas thermometers separately with a mercury thermometer, or other secondary standard. But by using a pair of bulbs like M and S simultaneously in the same bath, and measuring the small difference of pressure with an oil-gauge, a higher order of accuracy may be attained in the measurement of the small differences than by the method of indirect comparison. For instance, in the curves representing the difference between the nitrogen and hydrogen scales (fig. 1), as found by Chappuis by comparison of the nitrogen and hydrogen thermometers with the mercury thermometer, it is probable that the contrary flexure of the curve between 70° and 100° C. is due to a minute error of observation, which is quite as likely to be caused by the increasing aberrations of the mercury thermometer at these temperatures as by the difficulties of the manometric method. It may be taken as an axiom in all such cases that it is better to measure the small difference itself directly than to deduce it from the much more laborious observations of the separate magnitudes concerned.

17. *Expansion Correction.*—In the use of the mercury thermometer we are content to overlook the modification of the scale due to the expansion of the envelope, which is known as Poggendorff's correction, or rather to include it in the scale correction. In the case of the gas thermometer it is necessary to determine the expansion correction separately, as our object is to arrive at the closest approximation possible to the absolute scale. It is a common mistake to imagine that if the rate of expansion of the bulb were uniform, the scale of the apparent expansion of the gas would be the same as the scale of the real expansion—in other words, that the correction for the expansion of the bulb would affect the value of the coefficient of expansion $1/T_0$ only, and would be without effect on the value of the temperature t deduced. A result of this kind would be produced by a constant error in the initial pressure on the manometric method, or by a constant error in the initial volume on the volumetric method, or by a constant error in the fundamental interval on any method, but *not* by a constant error in the coefficient of expansion of the bulb, which would produce a modification of the scale exactly analogous to Poggendorff's correction. The correction to be applied to the value of t in any case to allow for any systematic error or variation in the data is easily found by differentiating the formula for t with respect to the variable considered. Another method, which is in some respects more instructive, is the following :—

Let T be the function of the temperature which is taken as the basis of the scale considered, then we have the value of t given by the general formula (1), already quoted in § 3. Let dT be the correction to be added to the observed value of T to allow for any systematic change or error in the measurement of any of the data on which the value of T depends, and let dt be the corresponding correction produced in the value of t, then substituting in formula (1) we have,

$$t+dt = 100(T-T_0+dT-dT_0)/(T_1-T_0+dT_1-dT_0),$$

from which, provided that the variations considered are small, we obtain the following general expression for the correction to t,

$$dt = (dT-dT_0)-(dT_1-dT_0)t/100. \quad . \quad . \quad (14)$$

It is frequently simpler to estimate the correction in this manner, rather than by differentiating the general formula.

In the special case of the gas thermometer the value of T is given by the formula

$$T = pV/RM = pV/R(M_0-M_2), \quad . \quad . \quad . \quad (15)$$

where p is the observed pressure at any temperature t, V the volume of the thermometric bulb, and M the mass of gas remaining in the bulb. The quantity M cannot be directly observed, but is deduced by subtracting from the whole mass of gas M_0 contained in the apparatus the mass M_2 which is contained in the dead space and overflow bulb. In applying these formulae to deduce the effect of the expansion of the bulb, we observe that if dV is the expansion from 0° C., and V_0 the volume at 0° C., we may write

$$V=V_0+dV, \quad T=p(V_0+dV)/RM=(pV_0/RM)\ (1+dV/V_0),$$

whence we obtain approximately

$$dT = TdV/V_0 \quad . \quad . \quad . \quad . \quad . \quad (16)$$

If the coefficient of expansion of the bulb is constant and equal to the fundamental coefficient f (the mean coefficient between 0° and 100° C.), we have simply $dV/V_0=ft$; and if we substitute this value in the general expression (14) for dt, we obtain

$$dt=(T-T_1)ft=ft(t-100) \quad . \quad . \quad . \quad (17)$$

Provided that the correction can be expressed as a rational integral function of t, it is evident that it must contain the factors t and $(t-100)$, since by hypothesis the scale must be correct at the fixed points 0° and 100° C., and the correction must vanish at these points. It is clear from the above that the scale of the gas thermometer is not independent of the expansion of the bulb even in the simple case where the coefficient is constant. The correction is by no means unimportant. In the case of an average glass or platinum reservoir, for which f may be taken as 0·000025 nearly, the correction amounts to $-0{\cdot}0625°$ at 50° C., to 3·83° at 445° C., and to 22·5° at 1000° C.

The value of the fundamental coefficient f can be determined with much greater accuracy than the coefficient over any other range of temperature. The most satisfactory method is to use the bulb itself as a mercury weight thermometer, and deduce the cubical expansion of the glass from the absolute expansion of mercury as determined by Regnault. Unfortunately the reductions of Regnault's observations by different calculators differ considerably even for the fundamental interval. The values of the fundamental coefficient range from ·00018153 Regnault, and ·00018210 Broch, to ·00018253 Wüllner. The extreme difference represents an uncertainty of about 4 per cent. (1 in 25) in the expansion of the glass. This uncertainty is about 100 times as great as the probable error of the weight thermometer observations. But the expansion is even less certain beyond the limits of the fundamental interval. Another method of determining the expansion of the bulb is to observe the linear expansion of a tube or rod of the same material, and deduce the cubical expansion on the assumption that the expansion is isotropic. It is probable that the uncertainty involved in this assumption is greater in the case of glass or porcelain bulbs, on account of the difficulty of perfect annealing, than in the case of metallic bulbs.

Except for small ranges of temperature, the assumption of a constant coefficient of expansion is not sufficiently exact. It is therefore usual to assume that the coefficient is a linear function of the temperature, so that the whole expansion from 0° C. may be expressed in the form $dV=t(a+bt)V_0$, in which case the fundamental coefficient $f=a+100b$. Making this substitution in the formula already given, we obtain the whole correction

$$dt=(f+bT)t(t-100) \qquad . \quad . \quad . \quad . \quad (18)$$

It will be observed that the term involving b becomes of considerable importance at high temperatures. Unfortunately, it cannot be determined with the same accuracy as f, because the conditions of observation at the fixed points are much more perfect than at other temperatures. Provided that the range of the observations for the determination of the expansion is co-extensive with the range of the temperature measurements for which the correction is required, the uncertainty of the correction will not greatly exceed that of the expansion observed at any point of the range. It is not unusual, however, to deduce the values of b and f from observations confined to the range 0° to 100° C., in which case an error of 1 per cent., in the observed expansion at 50° C., would mean an error of 60 per cent. at 445°, or of 360 per cent. at 1000° C. (Callendar, *Phil. Mag.* December 1899). Moreover, it by no means follows that the average value of b between 0° and 100° C. should be the same as at higher or lower temperatures. The method of extrapolation would therefore probably lead to erroneous results in many cases, even if the value could be determined with absolute precision over the fundamental interval. It is probable that this expansion correction, which cannot be reduced or eliminated like many of the other corrections which have been mentioned, is the chief source of uncertainty in the realization of the absolute scale of temperature at the present time. The uncertainty is of the order of one part in five or ten thousand on the fundamental interval, but may reach 0·5° at 500° C., and 2° or 3° at 1000° C.

18. *Thermodynamical Correction.*—Of greater theoretical interest, but of less practical importance on account of its smallness, is the reduction of the scale of the gas thermometer to the thermodynamical scale. The deviations of a gas from the ideal equation $pv=R\theta$ may be tested by a variety of different methods, which should be employed in combination to determine the form of the characteristic equation. The principal methods by which the problem has been attacked are the following:—

(1) By the comparison of gas thermometers filled with different gases or with the same gas at different pressures (employing both gravimetric and manometric methods) the differences in their indications are observed through as wide a range of temperature as possible. Regnault, employing this method, found that the differences in the scales of the permanent gases were so small as to be beyond the limits of accuracy of his observations. Applying greater refinements of measurement, Chappuis and others have succeeded in measuring small differences, which have an important bearing on the type of the characteristic equation. They show, for instance, that the equation of van der Waals, according to which all manometric gas thermometers should agree exactly in their indications, requires modification to enable it to represent the behaviour of gases even at moderate pressures.

(2) By measuring the pressure and expansion coefficients of different gases between 0° and 100° C. the values of the fundamental zero (the reciprocal of the coefficient of expansion or pressure) for each gas under different conditions may be observed and compared. The evidence goes to show that the values of the fundamental zero for all gases tend to the same limit, namely, the absolute zero, when the pressures are indefinitely reduced. The type of characteristic equation adopted must be capable of representing the variations of these coefficients.

(3) By observing the variations of the product pv with pressure at constant temperature the deviations of different gases from Boyle's law are determined. Experiment shows that the rate of change of the product pv with increase of pressure, namely $d(pv)/dp$, is very nearly constant for moderate pressures such as those employed in gas thermometry. This implies that the characteristic equation must be of the type

$$v=F(\theta)/p+f(\theta) \qquad . \quad . \quad . \quad . \quad (19)$$

in which $F(\theta)$ and $f(\theta)$ are functions of the temperature only to a first approximation at moderate pressures. The function $F(\theta)$, representing the limiting value of pv at zero pressure, appears to be simply proportional to the absolute temperature for all gases. The function $f(\theta)$, representing the defect of volume from the ideal volume, is the slope of the tangent at $p=0$ to the isothermal of θ on the pv, p diagram, and is sometimes called the "angular coefficient." It appears to be of the form $b-c$, in which b is a small constant quantity, the "co-volume," of the same order of magnitude as the volume of the liquid, and c depends on the cohesion or co-aggregation of the molecules, and diminishes for all gases continuously and indefinitely with rise of temperature. This method of investigation has been very widely adopted, especially at high pressures, but is open to the objection that the quantity $b-c$ is a very small fraction of the ideal volume in the case of the permanent gases at moderate pressures, and its limiting value at $p=0$ is therefore difficult to determine accurately.

(4) By observing the cooling effect $d\theta/dp$, or the ratio of the fall of temperature to the fall of pressure under conditions of constant total heat, when a gas flows steadily through a porous plug, it is possible to determine the variation of the total heat with pressure from the relation

$$Sd\theta/dp=\theta dv/d\theta-v \qquad . \quad . \quad . \quad . \quad (20)$$

(See THERMODYNAMICS, § 10, equation 15.) This method has the advantage of directly measuring the deviations from the ideal state, since $\theta dv/d\theta=v$ for an ideal gas, and the cooling effect vanishes. But the method is difficult to carry out, and has seldom been applied. Taken in conjunction with method (3), the observation of the cooling effect at different temperatures affords most valuable evidence with regard to the variation of the defect of volume $c-b$ from the ideal state. The formula assumed to represent the variations of c with temperature must be such as to satisfy both the observations on the compressibility and those on the cooling effect. It is possible, for instance, to choose the constants in van der Waals's formula to satisfy either (3) or (4) separately within the limits of experimental error, but they cannot be chosen so as to satisfy both. The simplest assumption to make with regard to c is that it varies inversely as some power n of the absolute temperature, or that $c=c_0(\theta_0/\theta)^n$, where c_0 is the value of c at the temperature θ_0. In this case the expression $\theta dv/d\theta-v$ takes the simple form $(n+1)c-b$. The values of n, c and b could be calculated from observations of the cooling effect $Sd\theta/dp$ alone over a sufficient range of temperature, but, owing to the margin of experimental error and the paucity of observations available, it is better to make use of the observations on the compressibility in addition to those on the cooling effect. It is preferable to calculate the values of c and b directly from equation (20), in place of attempting to integrate the equation according to Kelvin's method (*Ency. Brit.* ed. ix. vol. xi. p. 573), because it is then easy to take account of the variation of the specific heat S, which is sometimes important.

Calculation of the Correction.—Having found the most probable values of the quantities c, b and n from the experimental data, the calculation of the correction may be very simply effected as follows: The temperature by gas thermometer is defined by the relation $T=pv/R$, where the constant R is determined from the observations at 0° and 100° C. The characteristic equation in terms of absolute temperature θ may be put in the form $\theta=pv/R'+q$, where q is a small quantity of the same dimensions as temperature, given by the relation

$$q=(c-b)p/R \qquad . \quad . \quad . \quad . \quad (21)$$

The constant R′ is determined, as before, by reference to the fundamental interval, which gives the relation $R'/R=1+(q_1-q_0)/100$, where q_1, q_0 are the values of q at 100° and 0° C. respectively.

The correction to be added to the fundamental zero T_0 of the gas thermometer in order to deduce the value of the absolute zero θ_0 (the absolute temperature corresponding to 0° C.) is given by the equation,

$$\theta_0-T_0=q_0-(q_1-q_0)\theta_0/100 \qquad . \quad . \quad . \quad (22)$$

The correction dt to be added to the centigrade temperature t by gas thermometer reckoned from 0° C. in order to deduce the corresponding value of the absolute temperature also reckoned from 0° C. is given by the relation, deduced from formula (14),

$$dt=(q-q_0)-(q_1-q_0)t/100, \qquad . \quad . \quad . \quad (23)$$

where q is the value at t° C. of the deviation $(c-b)p/R$. The formulae may be further simplified if the index n is a simple integer such as 1 or 2. The values of the corrections for any given gas at different initial pressures are directly proportional to the pressure.

Values of the Corrections.—If we take for the gas hydrogen the values $c=1\cdot5$ c.c. at 0° C., $b=8\cdot0$ c.c., with the index $n=1\cdot5$, which satisfy the observations of Joule and Thomson on the cooling effect, and those of Regnault, Amagat and Chappuis on the compressibility, the values of the absolute zero θ_0, calculated from Chappuis's values of the pressure and expansion coefficients at 100 cms. initial pressure, are found to be 273·10° and 273·05° respectively, the reciprocals of the coefficients themselves being 273·03 and 273·22. The corrections are small and of opposite signs. For nitrogen, taking $c_0=1\cdot58$, $b=1\cdot14$, $n=1\cdot5$, we find similarly 273·10° and 273·13° for the absolute zero, the correction θ_0-T_0 in this case amounting to nearly 1°. The agreement is very good considering the difficulty of determining the small deviations c and b, and the possible errors of the expansion and pressure-coefficients. It appears certain that the value of the absolute zero is within a few hundredths of a degree of 273·10°. Other observations confirm this result within the limits of experimental error. The value of the index n has generally been taken as equal to 2 for diatomic gases, but this does not satisfy either the observations on the cooling effect or those on the compressibility so well as $n=1\cdot5$, although it makes comparatively little difference to the value of the absolute zero. The value deduced from Travers's observation of the pressure-coefficient of helium is 273·13°, taking $n=\frac{1}{2}$, which is the probable value of the index for a monatomic gas. The application of the method to the condensible gas carbonic acid is interesting as a test of the method (although the gas itself is not suited for thermometry), because its deviations from the ideal state are so large and have been so carefully studied. The observations of Joule and Thomson on the cooling effect give $c_0=3\cdot76$ c.c., $b=0\cdot58$ c.c., $n=2$, provided that allowance is made for the variation of the specific heat with temperature as determined by Regnault and Wiedemann. Chappuis's values of the pressure and expansion coefficients agree in giving 273·05° for the absolute zero, the values of the corrections θ_0-T_0 being 4·6° and 5·8° respectively.

The values of the scale correction dt deduced from these formulae agree with those experimentally determined by Chappuis in the case of carbonic acid within the limits of agreement of the observations themselves. The calculated values for nitrogen and hydrogen give rather smaller differences than those found experimentally, but the differences themselves are of the same order as the experimental errors. The deviations of hydrogen and helium from the absolute scale between 0° and 100° C. are of the order of ·001° only, and beyond the limits of accuracy of experiment. Even at −250° C. (near the boiling-point of hydrogen) the corrections of the constant volume hydrogen and helium thermometers are only a tenth of a degree, but, as they are of opposite signs, the difference amounts to one-fifth of a degree at this point, which agrees approximately with that observed by Travers. For a fuller discussion of the subject, together with tables of corrections, the reader may refer to papers by Callendar, *Phil. Mag.* v. p. 48 (1903), and D. Berthelot, *Trav. et Mém. Bur. Int. Paris*, xiii. (1903). Berthelot assumes a similar type of equation to that given above, but takes $n=2$ in all cases, following the so-called law of corresponding states. This assumption is of doubtful validity, and might give rise to relatively large errors in the case of monatomic gases.

19. *Limitations.*—In the application of the gas thermometer to the measurement of high temperatures certain difficulties are encountered which materially limit the range of measurement and the degree of accuracy attainable. These may be roughly classified under the heads—(1) changes in the volume of the bulb; (2) leakage, occlusion and porosity; (3) chemical change and dissociation. The difficulties arise partly from defects in the materials available for the bulb, and partly from the small mass of gas enclosed. The troubles due to irregular changes of volume of glass bulbs, which affect the mercury thermometer at ordinary temperatures, become so exaggerated at higher points of the scale as to be a serious source of trouble in gas thermometry in spite of the twentyfold larger expansion. For instance, the volume of a glass bulb will be diminished by from one-quarter to one-half of 1 per cent. the first time it is heated to the temperature of boiling sulphur (445° C.). This would not matter so much if the volume then remained constant. Unfortunately, the volume continues to change, especially in the case of hard glass, each time it is heated, by amounts which cannot be predicted, and which are too large to neglect. The most accurate method of taking account of these variations in a series of observations, without recalibrating and refilling and cleaning the bulb, is to assume the known constant value of the coefficient of expansion of the gas, and to calculate the volume of the bulb at any time by taking observations in ice and steam (*Phil. Trans.* A. 1891, vol. 182, p. 124). Similar changes take place with porcelain at higher temperatures. Metallic bulbs are far more perfect than glass bulbs in this respect. It is probable that silica bulbs would be the most perfect. The writer suggested the use of this material (in the *Journ. Iron and Steel Inst.* for 1892), but failed to construct bulbs of sufficient size. W. A. Shenstone, however, subsequently succeeded, and there seems to be a good prospect that this difficulty will soon be minimized. The difficulties of leakage and porosity occur chiefly with porcelain bulbs, especially if they are not perfectly glazed inside. A similar difficulty occurs with metallic bulbs of platinum or platinum-iridium, in the case of hydrogen, which passes freely through the metal by occlusion at high temperatures. The difficulty can be avoided by substituting either nitrogen or preferably argon or helium as the thermometric material at high temperatures. With many kinds of glass and porcelain the chemical action of hydrogen begins to be appreciable at temperatures as low as 200° or 300° C. In any case, if metallic bulbs are used, it is absolutely necessary to protect them from furnace gases which may contain hydrogen. This can be effected either by enclosing the bulb in a tube of porcelain, or by using some method of electric heating which cannot give rise to the presence of hydrogen. At very high temperatures it is probable that the dissociation of diatomic gases like nitrogen might begin to be appreciable before the limit of resistance of the bulb itself was reached. It would probably be better, for this reason, to use the monatomic and extremely inert gases argon or helium.

20. *Other Methods.*—Many attempts have been made to overcome the difficulties of gas pyrometry by adopting other methods of measurement. Among the most interesting may be mentioned: (i.) The variation in the wave-length of sound. The objection to this method is the difficulty of accurately observing the wave-length, and of correcting for the expansion of the material of the tubes in which it is measured. There is the further objection that the velocity varies as the square root of the absolute temperature. (ii.) A similar method, but more promising, is the variation of the refractivity of a gas, which can be measured with great accuracy by an interference method. Here again there is difficulty in determining the exact length of the heated column of gas, and in maintaining the temperature uniform throughout a long column at high temperatures. These difficulties have been ingeniously met by D. Berthelot (*Comptes Rendus*, 1895, 120, p. 831). But the method is not easy to apply, and the degree of accuracy attainable is probably inferior to the bulb methods. (iii.) Methods depending on the effusion and transpiration of gases through fine orifices and tubes have been put in practice by Barus and by the writer. The method of transpiration, when the resistance of the tube through which the current of gas is passed is measured on the Wheatstone bridge principle (*Nature*, 23rd March 1899), is extremely delicate, and the apparatus may be made very small and sensitive, but the method cannot be used for extrapolation at high temperatures until the law of increase of resistance has been determined with certainty. This may be successfully accomplished in the near future, but the law is apparently not so simple as is usually supposed.

On account of these and similar difficulties, the limit of gas thermometry at the present time must be placed at 1500° C., or even lower, and the accuracy with which temperatures near 1000° C. are known does not probably exceed 2° C. Although measurements can be effected with greater consistency than this by means of electrical pyrometers, the absolute values corresponding to those temperatures must remain uncertain to this extent, inasmuch as they depend on observations made with the gas thermometer.

Electrical Thermometry

21. The convenience of the mercurial thermometer lies in the fact that it is complete in itself, and can be read without subsidiary appliances beyond a magnifying glass. Its weakness lies in the very limited range of each single instrument, and in the troublesome and often uncertain corrections which must be applied to its readings in all work of precision. Electrical

thermometers have the disadvantage of requiring auxiliary apparatus, such as galvanometers and resistances, the use of which involves some electrical training. But they far surpass the mercurial thermometer in point of range, delicacy and adaptability, and can be applied to many investigations in which ordinary thermometers are quite useless.

There are two kinds of electrical thermometers, which depend on different effects of heat on the electrical properties of metals: (1) The *Thermocouple*, or *Thermopile*, which depends on the production of a thermoelectric force when the junctions of different metals in an electric circuit are at different temperatures; and (2) the *Electrical Resistance Thermometer*, the action of which depends on the fact that the resistance of a pure metal to the passage of an electric current increases very considerably when the temperature is raised. The theory of the thermocouple is discussed in the article THERMOELECTRICITY, as it possesses many points of interest, and has been studied by many skilful experimentalists. The electrical resistance thermometer is of more recent origin; but although the theory has been less fully developed, the practice of the method bids fair to surpass all others in the variety and accuracy of its applications. In order to secure the widest possible range and the greatest constancy, in either variety of electrical thermometer, advantage is taken of the great stability and infusibility characteristic of the metals of the platinum group. Other metals are occasionally used in work at low temperatures with thermocouples for the sake of obtaining a larger electromotive force, but the substitution is attended with loss of constancy and uncertainty of reduction, unless the range is greatly restricted.

22. *Applications of the Thermocouple.*—The principal uses of the thermocouple in thermometry are for measuring high temperatures, and for measuring small differences of temperature, more particularly when the temperature is required to be measured *at a point*, or in a very small space. The electromotive force of the couple depends only on the temperature at the plane of junction of the two metals, which can be very exactly located. A typical instance of a measurement to which the thermocouple is peculiarly suited, is the determination of the cyclical variations of temperature at accurately measured depths from one-tenth to one-hundredth of an inch in the metal of the cylinder of a heat engine, the interior surface of which is exposed to cyclical variations of temperature in the working of the engine.[1] The exact depth of the plane of junction can be measured without difficulty to the thousandth of an inch. The insertion of the wire makes the least possible disturbance of the continuity of the metal. There is no lag, as the thermometer itself is part of the metal. The instantaneous value of the temperature at any particular point of the stroke can be measured separately by setting a periodic contact to close the circuit of the galvanometer at the desired point. A further advantage is gained by measuring only the difference of temperature between two junctions of a thermocouple at different depths, instead of the whole interval from some fixed point. None of these advantages could be secured by the use of any ordinary thermometer; some depend on the fact that the method is electrical, but some are peculiar to the thermocouple, and could not be otherwise attained.

On the other hand, the thermocouple is not well suited for thermometry of precision on account of the smallness of the electromotive force, which is of the order of ten microvolts only per degree for the most constant couples. By the use of very delicate galvanometers it is possible to read to the hundredth or even in special cases to the thousandth of a degree on this small difference, but unfortunately it is not possible to eliminate accidental thermal effects in other parts of the circuit due to small differences of temperature and material. These accidental effects seldom amount to less than one or two microvolts even in the best work, and limit the accuracy attainable in temperature measurement to about the tenth of a degree with a single platinum thermocouple. This limit can be surpassed by using couples of greater thermoelectric power and less permanence, or by using a pile or series of couples, but in either case it is doubtful whether the advantage gained in power is not balanced by loss of simplicity and constancy. A method of avoiding these effects, which the writer has found to be of great use in delicate thermoelectric researches, is to make the whole circuit, including all the terminals and even the slide-wire itself, of pure copper. Platinoid, german silver, constantan and other alloys most commonly used for resistances and slide-wires, are particularly to be avoided, on account of their great thermoelectric power when connected to copper. Manganin and platinum-silver are the least objectionable, but the improvement effected by substituting copper is very marked. It is clear that this objection to the use of the couple does not apply so strongly to high temperatures, because the electromotive force of the couple itself is greater, and the accuracy attainable is limited by other considerations.

23. *The Resistance Thermometer.*—In practice the resistance thermometer is almost invariably made of platinum, since there is very seldom any advantage to be gained by the substitution of baser metals. The instrument is for this reason often referred to simply as the "platinum thermometer." It is important that the platinum should be pure, both for the sake of uniformity and also because the change of electrical resistance with temperature is greatly diminished by impurities. The observation of the fundamental coefficient, which is ·00390 (or rather larger than the coefficient of expansion of a gas) for the purest metal hitherto obtained, is one of the most delicate tests of the purity of the metal. In addition to the constancy and infusibility of the metal, a special advantage which is secured by the use of platinum is the close agreement of the thermodynamical scale with the platinum scale of temperature, as defined by the formula

$$pt = 100(R - R_0)/(R_1 - R_0), \quad . \quad . \quad . \quad (24)$$

in which the symbol pt stands for the temperature on the platinum scale centigrade, and R, R_1 and R_0 are the observed resistances of the thermometer at the temperatures pt, 100° and 0° C. respectively. A platinum thermometer is generally arranged to read directly in degrees of temperature on the platinum scale, just as a mercury thermometer is graduated in degrees of the mercury scale. The reduction to the scale of the gas thermometer is most conveniently effected by the difference formula

$$t - pt = dt(t - 100)/10{,}000, \quad . \quad . \quad . \quad (25)$$

in which d is a constant, called the difference-coefficient, the value of which for pure platinum is about 1·50, but varies slightly for different specimens. This formula was first given by the writer as the result of a series of comparisons of different platinum wires with each other and with other metals, and also with an air thermometer over the range 0° to 625° C. The platinum wire in these comparisons was enclosed inside the bulb of the air thermometer itself, and disposed in such a manner as to be at the mean temperature of the bulb in case the temperature was not quite uniform throughout (*Phil. Trans.* A. 1887, p. 161). The formula was subsequently verified by C. T. Heycock and F. H. Neville (*Journ. Chem. Soc.* February 1895), by the observation of a number of higher points up to the freezing-point of copper at 1082° C., which they showed to agree with the most probable mean of all the best determinations by various methods of gas thermometry. At still higher temperatures, beyond the present range of the gas thermometer, the writer has succeeded in obtaining presumptive evidence of the validity of the same formula by comparison with the scales of the expansion and the specific heat of platinum, which appear to follow similar laws (*Phil. Mag.* December 1899). If we assume that the coefficient of expansion of platinum, the coefficient of increase of resistance, and the specific heat are all three linear functions of the temperature, we obtain results which are in agreement within the limits of error of observation up to the fusing-point of platinum itself. The same formula has been independently verified by

[1] Hall, *Trans. Amer. Inst. Elect. Eng.* 1891, vol. viii. p. 226; Callendar and Nicolson, *Proc. Inst. C. E.* vol. cxxxi. p. 1.

the comparison of platinum thermometers with the constant-volume nitrogen thermometer by Harker and Chappuis (*Phil. Trans.* A. 1900), working at the International Bureau at Sèvres, over the range 0° to 650° C. It has also been shown to satisfy very closely the observations on the variation of electrical resistance of other metals over wide ranges of temperature. Although the theoretical explanation of the formula has not yet been given, owing to our ignorance of the true nature of electrical conduction and of the molecular constitution of metals, it may be regarded from an empirical point of view as being one of the most accurately established of all thermometric formulae. It will be observed that it also represents the simplest possible type of divergence from the thermodynamical scale.

24. *Methods and Apparatus.*—The methods of electrical thermometry may be roughly classified under two heads as (1) deflection methods, in which the temperature is deduced from the observed deflection of a galvanometer; and (2) balance methods, in which the resistance or the electromotive force is balanced against a known adjustable resistance or potential difference. The former methods are most suitable for rough work and rapid reading, the latter for accurate measurements. In the practice of the deflection method it is customary to use a movable-coil galvanometer, the sensitiveness of which can be varied by varying the resistance in circuit, or by varying the stiffness of the suspension. The accuracy attainable is of the order of one-half of 1 per cent. on the deflection, and is limited by variations of resistance of the galvanometer, and by the imperfect elasticity of the suspension. In any case the scale of the galvanometer should be calibrated or tested for uniformity. In this kind of work the thermocouple has the advantage over the resistance thermometer in that the latter requires an auxiliary battery to supply the current; but in many cases this is no disadvantage, because it permits a greater latitude of adjustment, and makes it possible to obtain greater power than with the thermocouple.

In cases where it is desired to obtain greater accuracy without abandoning the quickness of reading which is the principal advantage of the deflection method, it is possible to combine the two methods by balancing part of the potential difference by means of a potentiometer and using the galvanometer for the small changes only. In cases where the greatest accuracy is required, a very sensitive galvanometer should be used, and the whole of the potential difference should be balanced as nearly as possible, leaving very little to depend on the deflection of the galvanometer. The degree of sensitiveness and accuracy obtainable depends primarily on the delicacy of the galvanometer, on the power available, and on the steadiness of the conditions of experiment. For thermometry of precision the resistance thermometer possesses three very great advantages over the thermocouple: (1) The power available, owing to the use of a battery, is much greater; (2) it is possible completely to eliminate the errors due to accidental thermal effects by reversing the battery; (3) the Wheatstone bridge method can be employed in place of the potentiometer, so that the constancy of the battery is immaterial, and it is not necessary to use a standard cell. The conditions to be satisfied in the attainment of the greatest possible accuracy in the measurement of temperature by this method differ somewhat from those which obtain in ordinary measurements of resistance, so that a special type of apparatus has been evolved for the purpose, a brief description of which will be given.

25. *Compensated Bridge Apparatus.*—It is necessary that the thermometer should be connected to the measuring apparatus by wires or "leads" of considerable length, generally at least two or three metres, in order to avoid exposing the galvanometer and resistance box, or other delicate parts of the apparatus, to changes of temperature. It is also essential that the leads should not be too thick or heavy, for convenience in handling and to prevent conduction of heat along the stem of the thermometer. The resistance of that part of the leads which is exposed to variations of temperature necessarily changes, and would give rise to serious errors if it were not determined or compensated. The method now generally adopted in accurate work is to compensate the variations of resistance of the leads by an exactly similar pair of dummy leads called the "compensator" and connected as shown diagrammatically in fig. 6. The battery, consisting of a single cell, with a rheostat and reversing key in circuit, is connected to the terminals AB of the two equal resistance coils AG, GB, which form the ratio arms of the balance. These coils must be carefully tested for equality of temperature-coefficient, and placed in close proximity to each other so as to be always at the same temperature. If they are interwound on the same reel, they must be most carefully insulated from each other. In parallel circuit with the ratio coils are connected the compensator CC′ and the balancing resistances C′E, on one side of the bridge-wire EF, and the compensating resistances FP and the pyrometer and leads PRP′ on the other side. The galvanometer is connected to the point G between the ratio coils, and to the sliding contact D on the bridge-wire. Since the ratio coils are always equal, equal changes of resistance on either side of D are eliminated, and do not affect the balance. Thus the changes of the pyrometer leads PP′ are balanced by the equal changes of the compensator leads CC′ on the other side. As a further refinement, which is of some importance in delicate work, the ends of the compensator leads are connected by a short piece of the same wire as the pyrometer coil. For instance, in observing the variations of temperature of the steam in the cylinder of a steam engine at different points of the stroke with a very delicate thermometer made of wire one-thousandth of an inch in diameter (*Proc. Inst. C. E.*, vol. cxxxi. fig. 16, p. 23), the ends of the fine wire attached to the thick leads could not follow the rapid variations of temperature, and it was found necessary to adopt this device to eliminate the end-effect. It is also useful in other cases to eliminate the effect of conduction along the leads in cooling the ends of the fine wire coil. The balancing resistances C′E are made of some alloy such as manganin or platinum-silver, the resistance

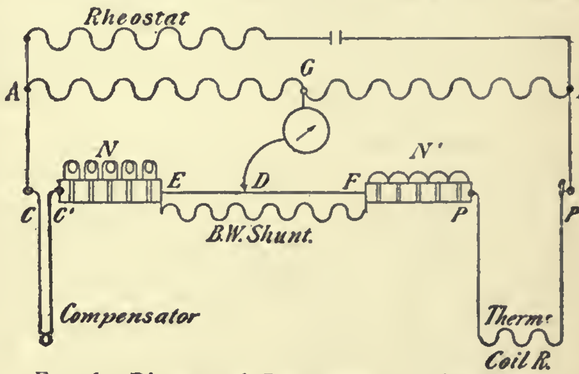

FIG. 6.—Diagram of Compensated Bridge Method.

of which varies very little with change of temperature. Platinum-silver is probably the best material, as it can be perfectly annealed at a red heat without risk of burning, and is then extremely constant. Unless the box can be kept at an absolutely constant and uniform temperature, which is not impossible but often inconvenient, it is necessary to allow for the change of resistance of the balancing coils C′E due to change in the temperature of the box. The temperature of the coils cannot be accurately determined with a mercury thermometer unless they are immersed in oil, but even in that case it is necessary to know the temperature-coefficient of each individual coil. A more convenient and accurate method, which eliminates the correction automatically, is to compensate each individual coil of the balancing coils C′E by a corresponding compensating coil at FP on the other side of the bridge-wire. The compensating coils are made of platinum, also annealed at a red heat, and each is placed in the box in close proximity to the coil it is intended to compensate. Each balancing coil and its compensator are tested together at various temperatures between 10° and 30° C., and are adjusted until their difference remains constant for any small variation of temperature in the neighbourhood of 20° C. This method of compensation was applied by the writer in 1887, but has not been generally adopted on account of the labour involved in adjusting the coils. The absolute values of the resistances are immaterial, but it is necessary to know the relative values with the greatest possible accuracy. For this reason it is preferable to arrange the resistances in the binary scale, each resistance being equal to twice the next smaller resistance, or to the sum of all the smaller resistances, the two smallest resistances being made equal. This arrangement permits the greatest accuracy of comparison in the simplest manner with the fewest observations. The bridge-wire EF provides a continuous scale for reading small changes of resistance. Any change of resistance of the pyrometer coil necessitates the movement of the balance point D through an equivalent resistance along the bridge-wire. The equivalent resistance of the bridge-wire per unit length of the attached scale is preferably adjusted, by means of a shunt shown in parallel with it in fig. 5, to be an exact submultiple of the smallest resistance coil. It is usual also to adjust the resistances of the thermometers so that their fundamental intervals are convenient multiples of this unit, generally either 100, 200, 500, or 1000, so that the bridge-wire may read directly in degrees of temperature on the platinum scale. It is easy to get a scale of 10 cms. or more to the degree, and it is not difficult with a suitable galvanometer to read to the ten-thousandth part of a degree. The length of the bridge-wire itself need not be more than 20 or 30 cms., as the balancing resistances enable the scale to be indefinitely extended. Thus the instrument possesses the great advantage over the mercury thermometer that the most open scale may be easily secured without unwieldy length, and without restricting the range of each thermometer.

26. *Errors and Corrections.*—It is most instructive to consider the errors and corrections involved in platinum thermometry on the same lines as those on which the corresponding errors of the mercury thermometer have already been treated.

I. The changes of zero of the mercury thermometer arise chiefly from the small expansibility of mercury combined with the imperfect elasticity of the containing tube. In platinum thermometry the containing tube has nothing to do with the reading, and the effect of any possible strain of the fine wire of the coil is minimized by its small dimensions and by the large temperature-coefficient of the increase of resistance, which is more than twenty times greater than the coefficient of apparent expansion of mercury in glass. It is not surprising, therefore, that the changes of zero of a platinum thermometer should be practically negligible, provided that the wire is not strained and contaminated with impurities. It is probable that with ordinary care the changes of zero due to exposure to any given limits of temperature are in all cases less than the limit of accuracy of observation, due to other causes at the extreme limit of the range considered.

II. *The fundamental interval* of each thermometer must be determined as usual by observations in ice and steam, and a correction must be applied by the method already described in the case of the mercury thermometer. The difference of the temperature of the steam from 100° C. should be determined on the platinum scale by the approximate formula

$$dpt_1 = \cdot 985 dt_1 = \cdot 0362(H-760) - \cdot 000020(H-760)^2 \quad . \quad (26)$$

III. *Pressure Correction.*—The effect of change of pressure on a platinum thermometer of the ordinary tube form is of course nothing, as the wire itself is not exposed to the pressure. Even if the wire is naked and directly exposed to large changes of pressure, the change of reading is almost inappreciable. Similarly there is no source of error analogous to the effects of capillarity, which are so troublesome with delicate mercury thermometers.

IV. *Stem Exposure.*—The reading of a platinum thermometer with compensated leads depends only on the temperature of the coil of wire forming the bulb, and not on the temperature of the stem, provided that the immersion is sufficient to avoid errors due to conduction or convection along the stem. It is desirable that the top of the bulb should be immersed to a depth equal to from three to ten times the diameter of the tube, according to the accuracy required.

V. *Scale Correction.*—The reduction to the thermodynamical scale may be effected, within the limits of probable error of the most accurate measurements at present available, by the very simple difference formula (25) already given, over the whole range from −100° C. to +1100° C. This is in striking contrast with the mercury thermometer, which requires a cubic formula to cover the range 0° to 200° C. with equal accuracy. The value of the constant *d* in the formula varies but little, provided that the wire be fairly pure and the thermometers properly constructed. In order to determine its value in any special case, it is best to take an observation at the boiling-point of sulphur (S.B.P.) for temperatures above 0° C., or at that of oxygen for temperatures below 0° C. down to −200° C. It appears probable that there is a point of inflection in the curve of resistance-variation of platinum and some other metals in the neighbourhood of −200° C., and that the formula does not apply accurately below this point. It has become the custom to assume the boiling-point of sulphur (S.B.P.) under normal pressure to be 444·53° C., as determined by Callendar and Griffiths, using a constant-pressure air thermometer, and to take the rate of change of temperature with pressure as ·082° per mm. from Regnault's observations. According to experiments made at Kew Observatory with platinum thermometers (Chree, *Proc. R. S.*, 1900), the rate of change is somewhat larger than that given by Regnault's formula, namely, about ·090° per mm., and it appears desirable to determine this constant with greater accuracy. The difference between the above formulae reaches a tenth of a degree if the barometer differs by 12 mm. from 760 mm. The uncertainty in the absolute boiling-point of sulphur, however, is probably somewhat greater than one-tenth of a degree, on account of the uncertainty of the expansion correction of the gas thermometer (*Phil. Mag.*, December 1899). The thermodynamical correction of the gas thermometer, which amounts to half a degree at this point, is also to some extent uncertain, on account of the extrapolation. Provided, however, that some exact value of the S.B.P. is chosen for reference, for the reduction of observations with platinum thermometers, the results so reduced will be strictly comparable, and can be corrected at any subsequent time when the value of the S.B.P. is more accurately determined. The boiling-point of oxygen may be taken as −182·5° C. with sufficient approximation for a similar purpose.

VI. *Calibration Correction.*—The calibration of the resistance box and the bridge-wire corresponds to the calibration of the stem of the mercury thermometer, but the process is much simpler for several reasons. It is more easy to obtain a uniform wire than a uniform tube. The scale of the wire is much more open, it corresponds to a very small part of the whole scale, and the process of calibration is easier. One box when calibrated will serve for any number of thermometers of different ranges and scales, and covers the whole range of temperature (see CALIBRATION).

27. *Electrical Precautions.*—The platinum thermometer is so far superior to the mercury thermometer in all the points above enumerated that, if there were no other difficulties, no one would ever use a mercury thermometer for work of precision. In using a platinum thermometer, however, some electrical training is essential to obtain the best results. The manipulation and adjustment of a delicate galvanometer present formidable difficulties to the non-electrical observer. Bad contacts, faulty connexions, and defective insulation, are not likely to trouble the practised electrician, but present endless possibilities of error to the tyro. A useful discussion of these and similar details is given in the paper by Chree already referred to. Bad insulation of the pyrometer and connexions can easily be detected, in the compensated instrument already described, by disconnecting one of the C leads from the battery and one of the P leads from the bridge-wire. Under these conditions the galvanometer should not deflect if the insulation is perfect. Defective insulation is most likely to be due to damp in the thermometer at low temperatures. This source of error is best removed by drying and hermetically sealing the thermometers. Trouble from bad contacts generally arises from the use of plugs for the resistance coils. If plugs are used, they must be specially designed so as not to disturb each other, and must be well fitted and kept very clean. Mercury cups with large copper terminals, well amalgamated, as used with standard resistance coils, are probably the simplest and most satisfactory method of changing connexions. Accidental thermoelectric effects in the circuit are a possible source of error, as with the thermocouple, but they are always very small if the thermometer is properly constructed, and are relatively unimportant owing to the large E.M.F. available. In any case they may be completely eliminated by reversing the battery. The heating effect of the current through the thermometer is often negligible, but should be measured and allowed for in accurate work. With a current of ·01 ampere the rise of temperature should not exceed $\frac{1}{10}$ or $\frac{1}{100}$ of a degree. With a delicate galvanometer it is possible to read to the ten-thousandth of a degree with a current of only ·002 ampere, in which case the heating effect is generally less than $\frac{1}{1000}$ of a degree. It can be very easily measured in any case by changing from one cell to two, thus doubling the current in the thermometer, and quadrupling the heating effect. The correction is then applied by subtracting one-third of the difference between the readings with one and two cells from the reading with one cell. The correction is always very small, if a reasonably sensitive galvanometer is used, and is frequently negligible, especially in differential work, which is one of the most fruitful applications of the platinum thermometer.

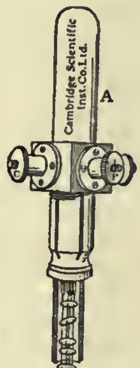

FIG. 7.—Platinum Thermometer.

28. *Construction of Thermometers.*—One of the chief advantages of the platinum thermometer for research work is the endless variety of forms in which it may be made, to suit the particular exigencies of each individual experiment. It is peculiarly suited for observing the average temperature throughout a length or space, which is so often required in physical experiments. For this purpose the wire may be disposed in a straight length, or in a spiral, along the space in question. Again, in observing the temperature of a gas, the naked wire, on account of its small mass and extremely low radiative power, is far superior to any mercury thermometer. The commonest form of platinum thermometer (fig. 7), and the most suitable for general purposes, contains a coil B from ½ in. to 2 in. long, wound on a cross of thin mica, and enclosed in a tube, about ¼ to ½ in. in diameter, of glass or porcelain according to the temperature for which it is required. The pyrometer leads and the compensator leads are insulated and kept in place by passing through mica disks fitting the tube, which serve also to prevent convection currents up and down the tube. The protecting tube of glass or porcelain is fitted with a wooden head A carrying four insulated terminals, PP, CC, to which the pyrometer

and compensator leads are respectively connected, and which serve to connect the instrument to the measuring apparatus. For work of the highest precision these terminals are often omitted, and the leads are directly soldered to a flexible cable in order to avoid possible errors from thermoelectric effects and changes of resistance of the screw terminals. For temperatures above 500° C. the protecting tube must be of porcelain, and the leads of platinum throughout that part of the tube which is exposed to high temperatures. For lower temperatures a tube of hard glass and leads of copper or silver may be employed, but it is better in any case to make the lower part of the leads of platinum in order to diminish the conduction of heat along the stem. For laboratory work a tube 30 or 40 cm. in length usually suffices, but for large furnaces the length of the protecting tube is often 5 to 10 ft. In the latter case it is usual to protect the porcelain tubes with an external steel tube, which may be removed for delicate measurements.

29. *Special Forms of Thermometer.*—In the measurement of linear expansion it is a great advantage to employ a thermometer with the bulb or sensitive portion equal in length to the bar or column under test, so as to obtain the mean temperature of the whole length. In measuring the linear expansion of a standard metre or yard, a fine platinum wire enclosed in a glass capillary, or otherwise insulated, is employed, its length being equal to that of the bar. The same method has been applied by Callendar (*Phil. Trans.* A, 1887) and Bedford (*Phil. Mag.*, 1898) to the expansion of glass and porcelain at high temperatures, employing a fine wire supported along the axis of the tube under test. An equivalent method, applied to the expansion of silica by Callendar, is to enclose a rod of the material inside a platinum tube which is heated by an electric current. This is a very rapid and convenient process, since the mean temperature of the rod must be equal to that of the enclosing tube. Any temperature up to the melting-point of platinum is readily obtained, and easily regulated. The temperature may be obtained by observing either the resistance of the platinum tube or its linear expansion. Either method may also be employed in J. Joly's meldometer, which consists of an electrically heated strip for observing the melting-points of minerals or other substances in small fragments. In observing the temperature of a long column of mercury, as in the method of equilibrating columns for determining the absolute expansion of mercury, a platinum thermometer with a bulb equal in length to the column may similarly be employed with advantage. The application is here particularly important because it is practically impossible to ensure perfect uniformity of temperature in a vertical column, 6 ft. or more in length, at high temperatures.

30. *Sensitive Thermometers.*—Where quickness of reading is essential, the mercury thermometer, or the tube form of electric thermometer, is unsuitable. In cases where the thermometer has to be immersed in a conducting liquid or solution, the fine wire forming the bulb may be insulated by enclosing it in a coiled glass capillary. This method has been employed by Callendar and Barnes and by Jaeger, but the instrument is necessarily fragile, and requires careful handling. For non-conducting liquids or gases the bare wire may be employed with great advantage. This is particularly important in the case of gases owing to the extreme sensitiveness thus obtained and the almost complete immunity from radiation error at moderate temperatures. Thermometers constructed in the form of a flat grid of bare wire mounted on a mica and ebonite frame have been employed by H. Brown (*Proc. R. S.*, 1905, B 76, p. 124) for observing the temperature of leaves and of air currents to which they were exposed. They have also been employed for observing the air-temperature for meteorological purposes in Egypt and Spain with very satisfactory results (*Proc. R. S.*, 1905, A 77, p. 7). The fine wire, owing to its small size and bright metallic surface, very rapidly acquires the temperature of the air, and is very little affected by radiation from surrounding objects, which is one of the chief difficulties in the employment of mercurial thermometers for the observation of the temperature of the air.

For the observation of rapidly varying temperatures, such as those occurring in the cylinder of a gas- or steam-engine, an electrical thermometer with very fine wire, of the order of ·001 in. diameter is practically the only instrument available. The temperature at any particular moment may be obtained by setting a mechanical contact-maker to close the circuit at the desired point. The sensitive part of the thermometer consists simply of a loop of fine wire from half an inch to an inch long, connected by suitable leads to the measuring apparatus as employed by Burstall (*Phil. Mag.*, October 1895) in the gas-engine, and Callendar and Nicolson (*Proc. Inst. C. E.*, 1898) in the steam-engine. The explosion temperatures cannot be satisfactorily measured in a gas-engine in this manner, because the radiation error at high temperatures is excessive unless the wire is very fine, in which case it is very soon melted even with weak mixtures. Callendar and Dalby accordingly devised a mechanical valve (*Proc. R. S.*, A 80, p. 57) for exposing the thermometer only during the admission and compression strokes, and have deduced the actual explosion temperatures from the indicator diagram. B. Hopkinson (*Proc. R. S.*, A 77, p. 387) succeeded in following the course of an explosion in a closed vessel by means of a similar thermometer connected to a galvanometer of short period giving a continuous record on a moving photographic film. When the flame reached the wire the temperature rose 1200° C. in about $\frac{1}{50}$ of a second, which illustrates the order of sensitiveness attainable with a fine wire of this size. O. R. Lummer and E. Pringsheim, in their measurements of the ratio of the specific heats of gases by observing the fall of temperature due to sudden expansion, employed a very thin strip of foil with the object of securing greater sensitiveness. This was a somewhat doubtful expedient, because such a strip is extremely fragile and liable to be injured by air currents, and because the sensitiveness is not as a matter of fact appreciably improved, whereas the radiation error is increased in direct proportion to the surface exposed. One of the principal sources of error in employing a short loop of fine wire for observing rapidly varying temperatures is that the ends of the loop close to the thick leads are affected by conduction of heat to or from the leads, and cannot follow the rapid variations of temperature. This error may be readily avoided by the method first employed by Callendar and Nicolson, of connecting the compensating leads with a short length of the same fine wire. The end effect is then eliminated by observing the difference of resistance between two loops of different lengths. Thermocouples of very fine wire have also been employed for similar measurements, but they are more difficult to make than the simple loop of one wire, and the sensitiveness attainable is much less, owing to the small E.M.F. of a single thermocouple.

31. *Radiation Thermoscopes.*—For measuring the intensity of radiation, some form of thermometer with a blackened bulb or sensitive area is employed. It is assumed that the rise of temperature of the thermometer is approximately proportional to the intensity of the radiation according to Newton's law of cooling (see HEAT) for small differences of temperature. A mercury maximum thermometer with a small blackened bulb is still very generally employed in meteorological observatories for registering the maximum solar radiation. But the indications are liable to error and very difficult to interpret, and an instrument of this type is not sufficiently sensitive or quick in action for weak sources of radiation. Sir John Leslie employed an air thermoscope, similar to that of Galileo (HEAT, fig. 1), with a blackened bulb. This has the advantage of a small capacity for heat, and is still employed in various forms for demonstration purposes, but is not sufficiently sensitive for accurate work. Electrical thermometers are now generally employed on account of their superior sensitiveness, and also on account of the greater facility of adaptation for the requirements of each particular experiment. The most familiar instrument is M. Melloni's thermopile, which is built up of a number of small bars of antimony and bismuth, or other alloys of high thermoelectric power, arranged in the form of a cube with alternate junctions on opposite faces. When connected to a galvanometer of suitable resistance, this arrangement gives a high degree of sensitiveness on account of the multiplication of couples, but owing to the large mass of metal involved in its construction it takes a considerable time to acquire a steady state. This defect has been remedied in the radiomicrometer of C. V. Boys (*Phil. Trans.*, 1888, 180 A, p. 159) by employing a single junction attached to a small disk of very thin copper. The free ends of the minute bars forming the couple are connected to a loop of thin copper wire suspended by a fine quartz fibre between the poles of a magnet. This arrangement forms a very delicate galvanometer and gives the maximum sensitiveness attainable with a single couple, since all unnecessary connecting wires are avoided. It is incomparably quicker and more dead-beat in action than the ordinary thermopile, but has the disadvantage that it must be set up permanently on a steady support and the radiation brought to it in a horizontal direction. An instrument of similar delicacy is the radiometer, the action of which depends on the repulsive effect of the residual gas in a nearly perfect vacuum on a delicately balanced vane suspended by a fine fibre. An instrument of this type was first constructed by Sir William Crookes (see RADIOMETER); the instrument was applied to radiation measurements, and its sensitiveness greatly improved by E. F. Nichols. It requires a very steady mounting, like the radiomicrometer, but has the additional defect that the radiation must be introduced through a window, which may give rise to selective absorption. Other varieties of thermopile, in which the sensitive parts are constructed, as in Boys' radiomicrometer, so as to have a very small capacity, but are connected like the ordinary pile to a separate galvanometer, have been employed by Lord Rosse for observations of lunar heat and by W. H. Julius and Callendar for the solar corona.

In cases where the radiation can be concentrated on a very small area, such as the receiving disk of the radiomicrometer, the thermoelectric method is probably the most sensitive. But if there is no restriction as to the area of the receiving surface, considerable advantage may be gained in convenience of manipulation, without loss of sensitiveness, by the electric resistance method. An instrument of this type was first employed by S. P. Langley (*Proc. Amer. Acad.*, 1881, 16, p. 342) under the name of the bolometer, by which it has since been known. The sensitive surface is made in the form of a blackened grid of thin metallic foil, generally platinum coated with platinum black, connected in one of the arms of a Wheatstone bridge. The rise of temperature of the grid when exposed to radiation is measured by its increase of resistance in the usual manner. In order to compensate for changes of temperature of the surrounding air the balancing resistance is made of a precisely similar grid, placed in close proximity to the first but screened from radiation. The foil should be as thin as possible consistent with strength, in order to secure the maximum sensitiveness. For spectroscopic work a single strip or linear bolometer is employed. For absolute measurements, where it is necessary to absorb the whole radiation admitted through a given area, two grids are placed with the strips of one behind the interspaces of the other.

32. *Absolute Measurement of Radiation.*—In many cases the object is not to secure the maximum degree of sensitiveness, but an absolute measurement of the intensity of the radiant energy, in calories per square centimetre per minute, or other suitable units. For this purpose some form of radiation thermometer is generally employed, but the method of procedure is modified. The earlier methods as exemplified in C. S. M. Pouillet's pyrheliometer, or L. J. G. Violle's actinometer, consisted in observing the rate of rise of temperature of a small calorimeter, or thermometer of known thermal capacity, when exposed to a given area of the radiation to be measured. To secure greater sensitiveness A. P. P. Crova substituted a copper disk with an attached thermocouple for the calorimetric thermometer. The method is very simple and direct, but has the disadvantage that the correction for external loss of heat is somewhat uncertain and difficult to apply, since the conditions are unsteady and the observation depends on rate of change of temperature. For this reason static methods, depending on the steady temperature finally attained, in which the rate of loss of heat is directly determined by an electric compensation method, have come more prominently into favour in recent years. In K. J. Ångström's pyrheliometer (*Acta Soc. Upsala*, 1893) two similar blackened strips of equal area and resistance are fixed side by side in a suitable case in such a manner that either may be exposed to the radiation to be measured while the other is simultaneously heated by an electric current. Attached to the backs of the strips, but insulated from them by thin paper, are the two junctions of a thermocouple which indicates when the temperatures are equal. When this condition is secured the intensity of the radiation is equal to the rate of generation of heat per unit area by the electric current, which is deduced, from a knowledge of the resistance and area of the strip, by observing the current required to balance the radiation. The instrument is very quick and sensitive in action, and the method avoids any assumption with regard to the rate of loss of heat, except that it is the same for the two similar strips at the same temperature. The accuracy of the method is limited chiefly by the measurement of the resistance and width of the strips, and by the difficulty of securing exact similarity and permanence in the attachment of the junctions of the thermocouple. Small differences in this respect may be eliminated by interchanging the strips, but there remain outstanding differences between different instruments of the same make which often exceed 5 per cent.

An electric method proposed by F. Kurlbaum (*Wied. Ann.*, 1898, 65, p. 748) consists in observing the rise of temperature produced by radiation in a bolometer grid, then cutting off the radiation and observing the increase of current required to produce the same rise of temperature. There is no difficulty in this case in measuring the area exposed or the resistance of the bolometer, and no uncertainty can arise as to the temperature of the strip, because the heated strip itself serves as its own thermometer. The current is easily deduced from a knowledge of the resistances and the E.M.F. of the battery. The chief source of uncertainty mentioned by Kurlbaum lies in possible differences between the effects of radiation and current-heating near the ends of the strips, the area so affected representing a large proportion of the whole area. In Ångström's method this is not so important because the temperature indicated by the couple is that near the middle of the strip. In the case of the bolometer this end-effect may be compensated, as explained by Callendar (*Proc. R. S.*, 1907, 77 A, p. 7), in the same manner as for sensitive thermometers, by employing two similar bolometers with strips of different lengths.

An important defect of all the methods so far considered is that the measurement depends on the coefficient of absorption of the black with which the receiving surface is coated. The error is probably small, of the order of 1 or 2 per cent., but is difficult to determine accurately, and varies to some extent with the quality of the radiation. The absorptive power is generally less for rays of great wave-length than for visible rays. If we assume that the loss of heat by conduction and convection is independent of the nature of the surface the defect in question may be avoided by the following method. Two bolometer strips, one bright and the other black, but otherwise exactly similar, are simultaneously exposed to the radiation to be measured, and are traversed by the same electric current. The black strip will be more heated by the radiation than the bright, but the rise of temperature of the bright strip due to the current will be greater than that of the black strip because its emissive power is lower. If the current is adjusted until the temperatures of the two strips are equal the losses by convection and conduction will be equal, and also the rate of generation of heat by the current in each strip. The rise of temperature must therefore be such that each strip loses as much heat by radiation to the surrounding case as it gains from the incident radiation to be measured. Assuming Kirchhoff's law, the ratio of the emissive to the absorptive power is the same for all bodies at the same temperature, and is equal to the emissive power of a perfectly black body. The rise of temperature of each strip, when balance is attained, will be the same as that of a perfectly black strip under the same conditions of exposure. The electric current in this method serves to eliminate losses by convection and conduction, and the result is obtained in terms of the observed rise of temperature and the radiation constant for a black body. The method works well for a source at 100° C.; but, for a high temperature source, a correction is required because the absorptive powers of the strips may differ appreciably from their emissive powers.

Another electric compensation method of special interest is the method of the "Peltier cross." A small disk of copper is supported by two thermoelectric couples forming a cross. One of the couples serves to measure the rise of temperature, while the other is traversed by an electric current, which may be employed to compensate the radiation by the heat absorption due to the Peltier effect. The advantage of this method is that the Peltier effect is easily determined from an observation of the thermoelectric power (see THERMOELECTRICITY) in absolute measure, and that it is proportional to the first power of the current. Loss or gain of heat by conduction from the supporting wires, and changes of temperature in the surrounding case, are readily compensated by mounting two similar disks side by side. Small differences between the disks are eliminated by exposing them to radiation alternately, with reversal of the current, so that the irradiated disk is cooled or the other disk heated by the Peltier effect. The current is adjusted in each case so that the temperatures of the disks are equal, as indicated by the second couple connecting the disks. The method is about equal in sensitiveness to that of Ångström, but it is easier to secure conditions of exact similarity and to measure the quantities involved in the absolute determination, namely, the area of the hole through which the radiation is admitted, and the coefficient of the Peltier effect. The uncertainty due to imperfect blackness of the disks may be eliminated by using cups in place of disks; and the sensitiveness and range may be increased by using thermopiles in place of single couples.

33. *Optical or Radiation Pyrometers.*—Since the intensity of radiation increases very rapidly with the temperature of the source of radiation, instruments for measuring radiation may be applied for measuring temperature, assuming that the laws connecting radiation and temperature are known. The advantage of this method is that the measurement may be made from a distance without exposing any part of the measuring apparatus to the destructive action of high temperatures. Apart from the difficulty of calibrating the measuring apparatus to give temperature in terms of radiation, the chief source of uncertainty in the application of the method is the emissive power of the source of radiation. The methods principally employed may be divided into two classes:—(1) Radiation methods, depending on the measurement of the radiant energy by means of a radiometer, thermocouple or bolometer; (2) optical or photometric methods, depending on the colour or luminous intensity of the radiation as compared with a suitable standard.

Of the radiation methods the simplest in theory and practice depends on observing the total intensity of radiation, which varies as the fourth power of the absolute temperature according to the Stefan-Boltzmann law (see HEAT) for a perfectly black body or full radiator. In applying this method it is very necessary to allow for the emissive power of the source, in case this does not radiate as a black body. Thus the emissive power of polished platinum at 1000° Abs. is only 10 per cent., and that of black iron oxide about 40 per cent. of that of a black body; and the percentage varies differently for different bodies with change of temperature, and also for the same body according to the part of the spectrum used, for the measurement. Owing to the rapid increase of radiation with temperature the error due to departure from black body radiation is not so serious as might be imagined at first sight. If the temperature of a polished platinum strip at 1500° C. were estimated by the radiation formula, assuming the constant for a perfectly black body, the error for red light would be about 125°, for green about 100°, and for blue about 75°. Such errors may be corrected when the emissive power of the source at various temperatures is known from previous experiments, but it is preferable to observe, whenever possible, the radiation from the interior of a uniformly heated enclosure which approximates very closely to that of a black body (see HEAT).

Radiation pyrometers of this type are generally calibrated by the method of sighting on the interior of an electric furnace containing a thermocouple or gas-thermometer by which the temperature is measured. The gas-thermometer has been employed for verifying the law of radiation up to 1500° C., but the difficulties of obtaining accurate results with the gas-thermometer increase so rapidly above 1200° C. that it is questionable whether any advantage is gained by using it beyond this point. The law of radiation has been so closely verified by observations at lower temperatures that the uncertainty involved in applying it at higher temperatures, in the case of a black body is probably less than the uncertainty of the gas-thermometer measurements, and much less than the uncertainty of extrapolating an empirical formula for a thermocouple. Thus L. F. C. Holborn and W. Wien (*Wied. Ann.*, 1895, (6), by extrapolating their thermoelectric formula, found the value 1587° C. for the melting-point of palladium, whereas Violle found 1500° C. by the calorimetric method, and Callendar and Eumorfopoulos (*Phil. Mag.*, 1899, 48) found 1540° and 1550° C. by the methods of the expansion and the change of resistance of platinum respectively. By a later thermoelectric extrapolation Holborn and Henning (*Berlin Akad.*, 1905, 12, p. 311) found 1535° C. for the melting-point of palladium, and 1710° C. for that of platinum, values which were strikingly confirmed by J. A. Harker at the National Physical Laboratory, and by Waidner and Burgess at the Bureau of Standards, U.S.A. Holborn and Valentiner employing an optical method (*Ann. Phys.*, 1907, 22, p. 1) found 1582° C. and 1789° C. for palladium and platinum respectively. There can be little doubt that the extrapolation of the parabolic formula for the thermocouple at these temperatures is quite untrustworthy (see THERMOELECTRICITY) and that the values given by the electrical resistance method, or by the laws of radiation, are more likely to be correct. Assuming that the total radiation varies as the fourth power of the absolute temperature, a radiation pyrometer can be calibrated by a single observation at a known temperature, such as the melting-point of gold, 1062° C. if a black body is employed as the source; and its indications will probably be accurate at higher temperatures under a similar restriction. If the pyrometer is sighted on the interior of a furnace through a small observation

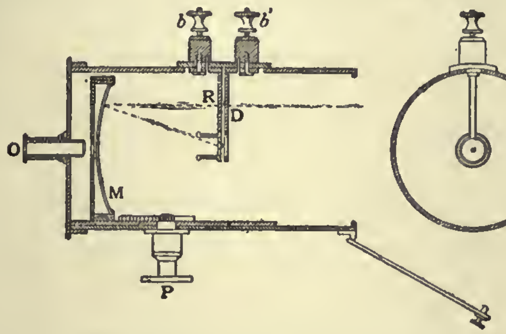

FIG. 8.—Féry's Mirror Pyrometer (Camb. Scient. Inst. Co.). For temperatures from 500° C. to 1100° C

hole it will indicate the temperature of the furnace correctly, provided that the temperature is uniform. But it must be remembered that this condition does not generally exist in large furnaces. Suppose, for instance, that it is required to find the temperature of the molten metal on the hearth of a furnace viewed through a thick layer of furnace gases, which are probably at a much higher temperature. It is evident that the radiation from the intervening flame may be much greater than that from the metal, and may introduce serious errors. The same objection applies with greater force to optical pyrometers, as the luminous radiation from gases may be of a highly selective character. If, on the other hand, it is required to observe the temperature of metal in a ladle before casting, the surface of the metal must be cleared of scum, and it is necessary to know the emissive power of the metal or oxide exposed.

For scientific measurements of temperature by the radiation method, the thermopile, or bolometer, or radiomicrometer, previously calibrated by exposure to a black body at a known temperature, is directly exposed at a known distance to a known area of the source of radiation. The required result may then be deduced in terms of the area and the distance. The use of extraneous optical appliances is avoided as far as possible on account of selective absorption. For practical purposes, in order to avoid troublesome calculations and measurements, an optical arrangement is employed, either lens or mirror, in order to form an image of the source on the receiving surface. Fig. 8 illustrates Féry's mirror pyrometer, in which a mirror M, focused by the pinion P, forms an image of the source on a disk, supported by wires of constantan and copper forming a thermocouple, connected by the brass strips D and R to the terminals *b*, *b'*. The observation hole in the wall of the furnace is sighted through the eyepiece O, and is made to overlap the disk slightly. The rise of temperature of the junction is assumed to be proportional to the intensity of radiation, and is indicated by the deflexion of a delicate galvanometer connected to the terminals *b*, *b'*. A lens may be substituted for the mirror at high temperatures, but it is necessary to allow for the selective absorption of the lens, and to a less extent for that of the mirror, by a special calibration of the scale.

Assuming Wien's laws for the distribution of energy in the spectrum (see HEAT), the temperature of a black body may also be measured by observing (1) the wave-length corresponding to maximum intensity in the normal spectrum, which varies inversely as the absolute temperature, or (2) the maximum intensity itself, which varies as the fifth power of the absolute temperature, or (3) the intensity of radiation corresponding to some particular radiation or colour, which varies as an exponential function, the exact form of which is somewhat uncertain. Methods (1) and (2) require elaborate apparatus and are impracticable except for purposes of scientific research. The *exact* application of method (3) is almost equally difficult, and is less certain in its results, but for optical purposes this method may be realized with a fair degree of approximation by the use of coloured glasses, and forms the basis in theory of the most trustworthy optical pyrometers.

34. *Optical or Photometric Pyrometers.*—The change of colour of a heated body from red to white with rise of temperature, and the great increase of intrinsic brilliancy which accompanies the change, are among the most familiar methods of estimating high temperatures. For many processes eye estimation suffices, but a much greater degree of accuracy may be secured by the employment of suitable photometers. In Mesuré and Nouel's pyrometric telescope, the estimation of temperature depends on observing the rotation of a quartz polarimeter required to reduce the colour of the radiation to a standard tint. It has the advantage of requiring no auxiliary apparatus, but, owing to the lack of a standard of comparison, its indications are not very precise. In the majority of photometric pyrometers, a standard of comparison for the intensity of the light, either an amyl-acetate or gasoline lamp, or an electric glow-lamp, is employed. The optical pyrometer of H. L. Le Chatelier (*Comptes Rendus*, 1892, 114, p. 214) was one of the earliest, and has served as a model for subsequent inventors. The standard of comparison is an amyl-acetate lamp, the flame of which is adjusted in the usual manner and viewed in the same field as the image of the source. The two halves of the field are adjusted to equality of brightness by means of a cat's eye diaphragm and absorption glasses, and are viewed through a red glass, giving nearly monochromatic radiation in order to avoid the difficulty of comparing lights of different colours. Assuming Wien's law, the logarithm of the intensity of monochromatic radiation for a black body is a linear function of the reciprocal of the absolute temperature, and the instrument can be graduated by observing two temperatures; but it is generally graduated at several points by comparison with temperatures observed by means of a thermocouple.

The Wanner Pyrometer (*Phys. Zeits.*, 1902, p. 112) is a modification of Konig's spectrophotometer, in which the two halves of the field, corresponding to the source and the standard of comparison, are illuminated with monochromatic red light polarized in planes at right angles to each other. The two halves may be equalized by rotating the analyzer, the circle of which is graduated to read in degrees of temperature. The instrument has a somewhat restricted range of maximum sensitiveness, and cannot be used below 900° C. owing to the great loss of light in the complicated optical system. It cannot be sighted directly on the object since no image is formed as in the Le Chatelier or Féry instruments, but the methods of securing monochromatic light by a direct vision spectroscope, and of adjusting the fields to equality by rotating the analyser, are capable of great precision, and lead to simple theoretical formulae for the ratio of the intensities in terms of Wien's law.

The Féry Absorption Pyrometer (*Journ. Phys.*, 1904, p. 32) differs from Le Chatelier's only in minor details, such as the replacement of the cat's eye diaphragm by a pair of absorbing glass wedges. The principles of its action and the method of calibration are the same. The pyrometers of Morse, and of L. F. C. Holborn and F. Kurlbaum depend on the employment of a glow lamp filament as standard of comparison, the current through which is adjusted to make the intrinsic brilliancy of the filament equal to that of the source. When this adjustment is made the filament becomes invisible against the image of the source as background, and the temperature of the source may be determined from an observation of the current required. Each lamp requires a separate calibration, but the lamps remain fairly constant provided that they are not overheated. To avoid this, the source is screened by absorption glasses (which also require calibration) in observing high temperatures. Except at low temperatures the comparison is effected by placing a red glass before the eyepiece. At low temperatures a special advantage of the glow-lamp as a standard of comparison is that it matches the source in colour as well as in brightness, so that the instrument is very sensitive. At high temperatures the red glass serves chiefly to mitigate the glare.

35. *Registering and Recording Thermometers.*—The term registering thermometer is usually applied to an instrument with an index which requires setting, and when set will indicate the maximum or minimum temperature occurring, or will register the temperature at a particular time or place. A recording instrument is one constructed to give a continuous record of the temperature, and requires a revolving drum or some equivalent clockwork mechanism

for recording the time. The most familiar types of registering thermometers are modifications of the common liquid-in-glass thermometer.

John Rutherford's maximum, invented before 1790, was an ordinary mercurial thermometer placed horizontally; the column pushed before it a small steed index which was left at the highest point reached and was drawn down again to the liquid by a magnet when the instrument had to be reset. It is little used now. Negretti and Zambra's maximum has a constriction in the tube near the bulb, past which the mercury easily expands but cannot return when the temperature falls, since the column breaks at the narrowed point when the fluid in the bulb begins to contract. The instrument is set for a fresh observation by shaking the detached portion of the column back down the tube. The clinical thermometers used by physicians are instruments of this type, and are made with a very open scale to read only in the neighbourhood of the normal temperature of the human body. In the Phillips or Walferdin maximum a portion of the mercury is separated from the rest by a minute bubble of air. It is placed horizontally and as the temperature rises the detached portion of the column is pushed forward but is not withdrawn when the main column retreats towards the bulb in cooling. It is set for a new observation by bringing it into a vertical position and tapping it slightly. By reducing the length of the index and the bore of the stem this thermometer may be made suitable for use in any position without altering its register.

The minimum thermometer in most common use is that of Rutherford, invented in 1790. It is a spirit thermometer, preferably filled with amyl alcohol, to reduce risk of distillation, in the column of which a small porcelain index is included. The instrument is hung horizontally, and, as the temperature falls, the index is drawn back through surface tension by the end of the column. When the temperature rises the liquid flows past the index, which is left at the lowest point attained. To prepare the instrument for a fresh observation it is inverted, when the index falls back against the end of the column. James Six's combined maximum and minimum thermometer (*Phil. Trans.*, 1782) consists of a U-tube, the bend of which is filled with mercury. One leg contains spirit above the mercury and terminates in a bulb also full of spirit. The other leg also contains a column of spirit above the mercury, but terminates in a bulb containing air and vapour of spirit mixed. With increase of temperature the spirit in the full bulb expands; the mercury in consequence is pushed round the bend and rises to a greater or less extent in the other leg, carrying before it a steel index which thus marks the maximum temperature. With cold the spirit in the full bulb contracts, and the mercury moves back carrying with it a second index which marks the minimum temperature. The instrument is set by drawing down the two indices upon the two ends of the mercury column by means of a magnet.

With a mercury thermometer a continuous record of temperature can only be obtained by the aid of photography, a method which has been in use for many years at some first-class observatories, but which cannot be generally employed on account of the expense and the elaborate nature of the apparatus required. The commonest type of recording thermometer works on the principle of the Bourdon pressure-gauge. The bulb consists of a curved metallic tube filled with liquid, the expansion of which with rise of temperature tends to straighten the tube. The movements are recorded on a revolving drum by a pen carried at the end of a light lever attached to the bulb. This form of instrument is widely employed for rough work, but it has a very limited range and is unsuitable for accurate work on account of want of sensitiveness and of great liability to change of zero, owing to imperfect elasticity of the metal tube. For accurate work, especially at high temperatures, electrical thermometers possess many advantages, and are often the only instruments available. They are comparatively free from change of zero over long periods, and the thermometer or pyrometer itself may be placed in a furnace or elsewhere at a considerable distance from the recording apparatus. The principal types are the thermocouple and the platinum resistance thermometer already described, which may be employed for recording purposes, without altering the thermometer itself, by connexion to a suitable recording mechanism. The methods in use for recording the indications of electrical thermometers may be classified as in § 24 under the two headings of (1) deflexion methods and (2) balance methods. Deflexion methods, in which the deflexion of the galvanometer is recorded, are more suitable for rough work, and balance methods for accurate measurements. The most delicate and most generally applicable method of recording the deflexions of a mirror galvanometer is by photographing the movements of the spot of light on a moving film. Almost any required scale or degree of sensitiveness may be obtained in this manner, but the record cannot be inspected at any time without removal and development. Since the forces actuating the needle of the galvanometer are very small, it is out of the question to attach a pen or marking point directly to the end of the pointer for recording a continuous trace on a revolving drum, because the errors due to friction with the recording sheet would be excessive. This difficulty has been avoided in many electrical instruments by depressing the pointer so as to mark the paper only at regular intervals of a minute or so, leaving it completely free for the greater part of the time. The record thus obtained is discontinuous, but is sufficient for many purposes. For accurate measurement, or for obtaining an open scale over a particular range of temperature, it is necessary to employ some form of balance method as already explained in § 24.

36. *Electric Recorder, Balance Method.*—The application of the electric balance, potentiometer or Wheatstone-bridge for recording changes of resistance or electromotive force has been effected by employing a galvanometer of the movable coil type as a relay. The deflexion of the galvanometer to right or left, according as the resistance or E.M.F. increases or diminishes, is made to actuate one or other of a pair of motors for moving the contact point on the bridge wire and the recording pen on the drum in the corresponding direction. A continuous record free from friction error is thus obtained, since the galvanometer does not actuate the pen directly. With an electrical resistance thermometer it is possible in this way to obtain continuous pen-and-ink records on a scale of an inch or more to the degree, reading to ·01° C. and practically free from zero error over any desired range from $-200°$ to $+1500°$ C. With a thermocouple, employing the potentiometer method, the same apparatus can be used with advantage, but it is not possible to obtain so open a scale on account of the smallness of the thermoelectromotive force available.

The attainment of sufficient delicacy in the relay mechanism turns on the employment of a rotating or vibrating contact in combination with a moving coil galvanometer of the siphon-recorder type. This was first successfully effected by Callendar (*Trans. R. S. Canad.*, 1897) for records of radiation and temperature, and has since been applied to submarine telegraphy by S. G. Brown and by A. Muirhead. The mechanism of Callendar's electrical recorder, as arranged for temperature measurements, is described and illustrated in *Engineering*, May 26, 1899, and in a treatise on *Pyrometry* by Le Chatelier and Boudouard. Electrical recording instruments of both types are now coming into extensive use for industrial purposes in the measurement of furnace temperatures, &c., for which they are particularly suitable, because the recording apparatus can be placed at any distance from the furnaces which may be considered most convenient, and can be connected to any one of a set of furnaces in succession whenever it is desired to obtain a record.

AUTHORITIES.—There is no special work on the subject of thermometry in English, but most of the principles and methods are described in text-books on heat, of which Preston's *Theory of Heat* may be specially mentioned. For recent advances in thermometry the reader should consult the original papers, the most important of which have been cited. The greater part of the recent work on the subject will be found in the publications of the Bureau International des Poids et Mesures de Sèvres (Paris), of the Reichsanstalt (Berlin), of the Bureau of Standards, U.S.A. (Washington), and of the National Physical Laboratory (London). (H. L. C.)

THERMOPYLAE (Gr. θερμός, hot, and πύλη, gate), a Greek pass leading from Locris into Thessaly between Mount Oeta and the sea (Maliac Gulf). It is chiefly famous for the heroic defence made by Leonidas, the Spartan king, with 300 Spartan soldiers against the Persian army of Xerxes advancing upon Greece in 480 (see LEONIDAS and authorities there quoted). Two other famous battles took place at the pass. In 279 B.C. Brennus and the Gauls were checked for several months by a Greek army under the Athenian Calippus, and in 191 Antiochus of Syria vainly attempted to hold the pass against the Romans under M'. Acilius Glabrio. In the time of Leonidas the pass was a narrow track (probably about 14 yds. wide) under the cliff. In modern times the deposits of the Spercheius have widened it to a breadth of 1½ to 3 m. broad. The hot springs from which the pass derived its name still exist close to the foot of the hill. There is one large spring used as a bath and four smaller ones, and the water, which is of a bluish green colour and contains lime, salt, carbonic acid and sulphur, is said to produce good effects in cases of scrofula, sciatica and rheumatism. The accommodation for bathers is, however, quite inadequate.

For the topography see Grundy, *Great Persian War*, pp. 277–291.

THÉROIGNE DE MÉRICOURT, ANNE JOSÈPHE (1762–1817), a Frenchwoman who was a striking figure in the Revolution, was born at Marcourt (from a corruption of which name she took her usual designation), a small town in Luxembourg, on the banks of the Ourthe, on the 13th of August 1762. She was the daughter of a well-to-do farmer, Peter Théroigne. She appears to have been well educated, having been brought up in the convent of Robermont; she was quick-witted, strikingly handsome in appearance and intensely passionate in temper; and she had a vigorous eloquence, which she used with great effect upon the mobs of Paris during that short space of her life (1789–93) which alone is of historical interest. The story of her having been betrayed by a young *seigneur*, and having in consequence devoted her life to avenge her wrongs upon aristocrats, a story which is told by Lamartine and others, is unfounded, the truth being that she left her home on account of a quarrel with her stepmother. In her career as courtesan she visited London in 1782, was back in Paris in 1785, and in Genoa in 1788, where she was a concert singer. In 1789 she returned to Paris. On the outbreak of the Revolution, she was surrounded by a coterie of well-known men, chief of whom were Pétion and Desmoulins; but she did not play the rôle which legend has assigned her. She took no part in the taking of the Bastille nor in the days of the 5th and 6th of October, when the women of Paris brought the king and queen from Versailles. In 1790 she had a political salon and spoke once at the club of the Cordeliers. The same year she left Paris for Marcourt, whence after a short stay she proceeded to Liége, in which town she was seized by warrant of the Austrian Government, and conveyed first to Tirol and thereafter to Vienna, accused of having been engaged in a plot against the life of the queen of France. After an interview, however, with the emperor Leopold II., she was released; and she returned to Paris in January 1792, crowned of course with fresh laurels because of her captivity, and resumed her influence. In the clubs of Paris her voice was often heard, and even in the National Assembly she would violently interrupt the expression of any moderatist views. Known henceforth as "la belle Liégoise," she appeared in public dressed in a riding habit, a plume in her hat, a pistol in her belt and a sword dangling at her side, and excited the mob by violent harangues. Associated with the Girondists and the enemies of Robespierre, she became in fact the "Fury of the Gironde." She commanded in person the 3rd corps of the so-called army of the faubourgs on the 20th of June 1792, and again won the gratitude of the people. She shares a heavy responsibility for her connexion with the riots of the 10th of August. A certain contributor to the journal, the *Acts of the Apostles*, Suleau by name, earned her savage hatred by associating her name, for the sake of the play upon the word, with a deputy named Populus, whom she had never seen. On the 10th of August, just after she had watched approvingly the massacre of certain of the national guard in the Place Vendôme, Suleau was pointed out to her. She sprang at him, dragged him among the infuriated mob, and he was stabbed to death in an instant. She took no part in the massacres of September, and, moderating her conduct, became less popular from 1793. Towards the end of May the Jacobin women seized her, stripped her naked, and flogged her in the public garden of the Tuileries. The following year she became mad, a fate not surprising when one considers her career. She was removed to a private house, thence in 1800 to La Salpetrière for a month, and thence to a place of confinement called the Petites Maisons, where she remained—a raving maniac—till 1807. She was then again removed to La Salpetrière, where she died, never having recovered her reason, on the 9th of June 1817.

See M. Pellet, *Étude historique et biographique sur Théroigne de Méricourt* (1886); L. Lacour, *Les Origines du féminisme contemporain. Trois femmes de la Révolution* (Paris, 1900); Vicomte de Reiset, *La Vraie Théroigne de Méricourt* (Paris, 1903); E. and J. de Goncourt, *Portraits intimes du XVIII^e. siècle* (2 vols., 1857–58); and the play *Théroigne de Méricourt* of M. Paul Hervieu, produced at the Théâtre Sarah Bernhardt in 1902.

THERSITES, the ugliest man in the Greek camp before Troy, celebrated for his biting tongue. The special objects of his attack were the leaders of the army, and Homer (*Iliad*, ii. 212) tells how he was chastised by Odysseus for daring to abuse the commander-in-chief. According to a later story, Achilles, after he had slain the Amazonian queen Penthesilea, bitterly lamented her death; for this he was reviled by Thersites, who even insulted the body of the dead queen. Achilles thereupon slew Thersites with a blow of his fist (Quint. Smyrn. i. 722). There was a play by Chaeremon called *Achilles the Thersites-slayer*, probably a satyric drama, the materials of which were taken from the *Aethiopis* of Arctinus.

THESAURUS (Gr. θησαυρός), the term in architecture given to the Greek treasure house, and at one time applied to the beehive tombs of Mycenae and other parts of Greece, now recognized as tombs; the subterranean chambers under some of the Greek temples were probably used as treasure rooms. Sometimes in the rear of the cella of a Greek temple there was a chamber, known as the opisthodomus, in which the treasures were kept; and, failing this provision, the epinaos or rear portico of the temple was enclosed with large railings and utilized for the same purpose; in this case the term opisthodomus was applied to it. "Thesaurus" is also used of a dictionary, or lexicon, as being a "treasure house" or store of knowledge.

THESEUS, the great hero of Attic legend,[1] son of Aegeus, king of Athens, and Aethra, daughter of Pittheus, king of Troezen. Thus through his father he was descended from Erechtheus and the original stock of Attica; through his mother he came of the Asiatic house of Pelops. The legend relates that Aegeus, being childless, went to Pittheus, who contrived that Aegeus should have intercourse with his daughter Aethra, and that in due time Aethra brought forth Theseus. It was given out that the child's father was Poseidon, the great god of Troezen, and that Aethra raised a temple to Athena Apaturia, at which Troezenian maids used to dedicate their girdles before marriage. For his tutor and guardian young Theseus had one Cannidas, to whom, down to Plutarch's time, the Athenians were wont to sacrifice a black ram on the eve of the festival of Theseus. On passing out of boyhood Theseus was sent by his mother to Athens. He encountered many adventures on the way. First he met and slew Periphetes, surnamed Corynetes (Clubman). At the isthmus of Corinth dwelt Sinis, called the Pine-Bender, because he killed his victims by tearing them asunder between two pine-trees. Theseus hoisted the Pine-Bender on his own pine-tree. Next Theseus despatched the Crommyonian sow (or boar). Then he flung over a cliff the wicked Sciron, who used to kick his guests into the sea, while perforce they washed his feet. In Eleusis Theseus wrestled with Cercyon and killed him. A little farther on he slew Procrustes, who fitted all comers to his only bed: if his guest was too short for the bed, he stretched him out; if he was too long, he cut him down to the requisite length. As he passed through the streets of Athens, his curls and long garment reaching to his ankles drew on him the derision of some masons, who were putting on the roof of the new temple of Apollo Delphinius: "Why," they asked, "was such a pretty girl out alone?" In reply Theseus took the bullocks out of their cart and flung them higher than the roof of the temple. He found his father married to Medea, who had fled from Corinth. Being a witch, she knew Theseus before his father did, and tried to persuade Aegeus to poison his son; but Aegeus recognized him by his sword and took him to his arms. Theseus was now declared heir to the throne, and the Pallantids,[2] who had hoped to succeed to the childless king, conspired against Theseus, but he crushed the conspiracy. He then attacked the fire-breathing bull of Marathon and brought it alive to Athens, where he sacrificed it to Apollo Delphinius. Next came the adventure of the Cretan Minotaur (*q.v.*), whom Theseus slew by the aid of Ariadne (*q.v.*). While Theseus was in Crete, Minos,

[1] The story of Theseus is a strange mixture of (mostly fictitious) political tradition, of aetiological myths invented to explain misunderstood acts of ritual and of a cycle of tales of adventure analogous to the story of the labours of Heracles. All the passages in the *Iliad* and *Odyssey* in which his name or allusions to his legend occur are regarded with more or less probability as spurious (but see O. Gruppe, *Gr. Myth.*, i. p. 581).

[2] The sons of Pallas, the brother of Aegeus.

wishing to see whether Theseus was really the son of Poseidon, flung his ring into the sea. Theseus dived and brought it up, together with a golden crown, the gift of Amphitrite. On the return voyage the ship touched at Naxos, and there Theseus abandoned Ariadne. He landed also at Delos, and there he and his comrades danced the crane dance, the complicated movements of which were meant to imitate the windings of the Labyrinth.[1] In historical times this dance was still danced by the Delians round a horned altar. Theseus had promised Aegeus that, if he returned successful, the black sail with which the fatal ship always put to sea should be exchanged for a white one.[2] But he forgot his promise; and when Aegeus from the Acropolis at Athens descried the black sail out at sea, he flung himself from the rock and died. Hence at the festival which commemorated the return of Theseus there was always weeping and lamentation. Theseus now carried out a political revolution in Attica by abolishing the semi-independent powers of the separate townships and concentrating those powers at Athens, and he instituted the festival of the Panathenaea,[3] as a symbol of the unity of the Attic race. Further, according to tradition, he instituted the three classes or castes of the eupatrids (nobles), geomori (husbandmen), and demiurgi (artisans). He extended the territory of Attica as far as the isthmus of Corinth.

He was the first to celebrate in their full pomp the Isthmian games in honour of Poseidon; for the games previously instituted by Hercules in honour of Melicertes had been celebrated by night, and had partaken of the nature of mysteries rather than of a festival. Of Theseus's adventures with the Amazons there were different accounts. According to some, he sailed with Hercules to the Euxine, and there won the Amazon Antiope as the meed of valour; others said that he sailed on his own account, and captured Antiope by stratagem. Thereafter the Amazons attacked Athens. Antiope fell fighting on the side of Theseus, and her tomb was pointed out on the south side of the acropolis. By Antiope Theseus had a son, Hippolytus. On the death of Antiope, Theseus married Phaedra. She fell in love with her stepson Hippolytus, who, resisting her advances, was accused by her to Theseus of having attempted her virtue. Theseus in a rage imprecated on his son the wrath of Poseidon. His prayer was answered: as Hippolytus was driving beside the sea, a bull issuing from the waves terrified his horses, and he was thrown and killed. This tragic story is the subject of one of the extant plays of Euripides.[4]

The famous friendship between Theseus and Pirithous, king of the Lapiths, originated thus. Hearing of the strength and courage of Theseus, Pirithous desired to put them to the test. Accordingly he drove away from Marathon some cows which belonged to Theseus. The latter pursued, but when he came up with the robber the two heroes were so filled with admiration of each other that they swore brotherhood. At the marriage of Pirithous to Hippodamia (or Deidamia) a fight broke out between the Lapiths and Centaurs, in which the Lapiths, assisted by Theseus, were victorious, and drove the Centaurs out of the country. Theseus and Pirithous now carried off Helen from Sparta, and when they drew lots for her she fell to the lot of Theseus, who took her to Aphidnae, and left her in charge of his mother Aethra and his friend Aphidnus. He now descended to the lower world with Pirithous, to help his friend to carry off Proserpine. But the two were caught and confined in Hades till Heracles came and released Theseus. When Theseus returned to Athens he found that a sedition had been stirred up by Menestheus, a descendant of Erechtheus, one of the old kings of Athens. Failing to quell the outbreak, Theseus in despair sent his children to Euboea, and after solemnly cursing the Athenians sailed away to the island of Scyrus, where he had ancestral estates. But Lycomedes, king of Scyrus, took him up to a high place, and killed him by casting him into the sea. Long afterwards, at the battle of Marathon (490 B.C.), many of the Athenians fancied they saw the phantom of Theseus, in full armour, charging at their head against the Persians. When the Persian war was over the Delphic oracle bade the Athenians fetch the bones of Theseus from Scyrus, and lay them in Attic earth. It fell to Cimon's lot in 469 B.C. to discover the hero's grave at Scyrus and bring back his bones to Athens. They were deposited in the heart of Athens, and henceforth escaped slaves and all persons in peril sought and found sanctuary at the grave of him who in his life had been a champion of the oppressed. His chief festival, called Theseia, was on the 8th of the month Pyanepsion (October 21st), but the 8th day of every other month was also sacred to him.[5]

Whatever we may think of the historical reality of Theseus, his legend almost certainly contains recollections of historical events, *e.g.* the συνοικισμός, whether by this we understand the political centralization of Attica at Athens or a local union of previously separate settlements on the site of Athens. The birth of Theseus at Troezen points to the immigration of an Ionian family or tribe. With this agrees the legend of the contest between Athena and Poseidon for supremacy on the acropolis of Athens, for Theseus is intimately connected with Poseidon, the great Ionian god. Aegeus, the father of Theseus, has been identified by some modern scholars with Poseidon.

The well-preserved Doric temple to the north of the acropolis at Athens, commonly known as the Theseum, was long supposed to be the sanctuary in which the bones of Theseus reposed. But archaeologists have generally abandoned this conjecture. There were several (according to Philochorus, four) temples or shrines of Theseus at Athens. Milchhöfer considers he has found one of them in the neighbourhood of Peiraeus.[6]

Our chief authority for the legend of Theseus is the life by Plutarch, which is a compilation from earlier writers; see also Bacchylides. G. Gilbert, who has investigated the sources from which Plutarch drew for his life of Theseus, believes that his chief authority was the *Atthis* of Ister, and that Ister mainly followed Philochorus (*Philologus*, xxxiii., 1874, p. 46 sq.).

There is a modern Greek folk-tale which preserves some features of the legend of Theseus and the Minotaur, but for the Minotaur has been substituted a seven-headed snake. See Bernhard Schmidt, *Griechische Märchen, Sagen und Volkslieder* (1877), p. 118 sq.

Among modern monographs on Theseus may be mentioned: A. Schultz, *De Theseo* (Breslau, 1874); Th. Kausel, *De Thesei Synoikismo* (Dillenburg, 1882); E. Prigge, *De Thesei rebus gestis* (Marburg, 1891); O. Wulff, *Zur Theseussage* (Dorpat, 1892); see also O. Gruppe, *Griechische Mythologie*, i. pp. 581–608; J. E. Harrison, *Mythology and Monuments of Ancient Athens* (1890); "Der Theseische Synoikismos" in C. F. Hermann's *Lehrbuch der griechischen Staatsaltertümer*, i. (1892), pp. 303–306; A. Baumeister, *Denkmäler des klassischen Altertums*, iii. (1888).

THESMOPHORIA, an ancient Greek festival, celebrated by women only in honour of Demeter Θεσμοφόρος. At Athens, Abdera, and perhaps Sparta, it lasted three days. At Athens the festival took place on the 11th, 12th and 13th of the month

[1] The Ostiaks of Siberia have an elaborate crane dance, in which the dancers are dressed up with skins and the heads of cranes (P. S. Pallas, *Reise durch verschiedene Provinzen des russischen Reichs*, iii. 1778).

[2] So, too, the ship that sailed annually from Thessaly to Troy with offerings to the shade of Achilles put to sea with sable sails (Philostratus, *Heroica*, xx. 25). The ship that was to bring Iseult to the mortally wounded Tristram was to hoist a white sail if she was on board, a black sail if she was not. The black sails recur in the modern Greek version of the tale of Theseus. Cf. *Asiatick Researches*, ix. 97.

[3] Besides the Panathenaea Theseus is said to have instituted the festival of the *Synoikia* or *Metoikia*. Wachsmuth ingeniously supposes that the latter festival commemorated the local union in a single city of the separate settlements on the Acropolis and its immediate neighbourhood, while the Panathenaea commemorated the political union of the whole of Attica. (C. Wachsmuth, *Die Stadt Athen im Alterthum*, 1874, p. 453 sq.).

[4] Theseus is also said to have taken part in the Argonautic expedition and the Calydonian boar-hunt.

[5] The Athenian festival in October, popularly supposed to commemorate the return of Theseus from Crete, is interesting, as some of its features are identical with those of harvest-festivals still observed in the north of Europe. Thus the *eiresiōnē*, a branch of olive wreathed with wool and decked with fruits, bread, &c., which was carried in procession and hung over the door of the house, where it was kept for a year, is the *Erntemai* (Harvest-may) of Germany. See W. Mannhardt, *Antike Wald- und Feld-Kulte* (1877), p. 212 sq.

[6] See *Erläuternder Text* to the *Karten von Attika* (Berlin, 1881), i. p. 37 sq.

Pyanepsion (24th, 25th and 26th October), the first day being called Anodos (ascent), or, according to others, Kathodos (descent), the second Nesteia (fast), and the third Kalligeneia (fair-born).[1] If to these days we add the Thesmophoria, which were celebrated on the 10th at Halimus, a township on the coast near Athens, the festival lasted four days.[2] If further we add the festival of the Stenia, which took place on the 9th, the whole festival lasted five days.[3] The Stenia are said by Photius to have celebrated the return of Demeter from the lower world (Anodos), and the women railed at each other by night.[4] The Thesmophoria at Halimus seem to have included dances on the beach.[5] The great feature of the next day (the Anodos) is generally assumed to have been a procession from Halimus to Athens, but this assumption seems to rest entirely on an interpretation of the name Anodos, and it loses all probability when we observe that the day was by others called Kathodos.[6] Probably both names referred to the descent of Demeter or Persephone to the nether world, and her ascent from it.[7] The next day Nesteia, was a day of sorrow, the women sitting on the ground and fasting.[8] As to what took place on the Kalligeneia we have no information.[9] Nor can we define the time or nature of the secret ceremony called the "pursuit," or the "Chalcidian pursuit," and the sacrifice called the "penalty."[10]

During the Thesmophoria (and for nine days previously, if Ovid, *Met.*, x. 434, is right, and refers to the Thesmophoria) the women abstained from intercourse with their husbands, and to fortify themselves strewed their beds with *Agnus castus* and other plants. The women of Miletus strewed their beds with pine branches, and put fir-cones in the sanctuaries of Demeter.[11] Whether unmarried women were admitted to the festival seems doubtful; in Lucian's time it would appear that they were.[12] The women of each deme (township) elected two married women of their number to preside over them at the festival; and every married man in the township who possessed property to the value of three talents had to provide a feast for the women on behalf of his wife.[13] During the festival the women seem to have been lodged by twos in tents or huts, probably erected within the sacred precincts of the Thesmophorion.[14] They were not allowed to eat the seeds of the pomegranate or to wear garlands of flowers.[15] Prisoners were released at the festival,[16] and during the Nesteia the law-courts were closed and the senate did not meet.[17] Aristophanes's play on the festival sheds little light on the mode of its celebration.

At Thebes Thesmophoria were celebrated in summer on the acropolis (Cadmeia); at Eretria during the Thesmophoria the women cooked their meat, not at fires, but by the heat of the sun, and they did not invoke Kalligeneia (which seems to mean that they did not celebrate the last day of the festival); at Syracuse, during the festival, cakes called ***mylloi***, made of sesame and honey in the shape of ***pudenda muliebria***, were handed round.[18] Agrigentum, Ephesus and Dryme, in Phocis, had also their Thesmophoria.[19]

The above was nearly all that was known about the Thesmophoria down to 1870. In that year E. Rohde published in the *Rheinisches Museum*, n.s., xxv., p. 548 sq., a scholion on Lucian (*Dial. Meretr.*, ii. 1), which he discovered in the Vatican MS. Palatinus 73, and which furnishes some curious details about the Thesmophoria. It also explains two obscure and corrupt passages of Clemens Alexandrinus and Pausanias, the true meaning of which had been divined by Lobeck (*Aglaophamus*, p. 828). The substance of the scholion is this. When Persephone was carried off by Pluto, a swineherd called Eubuleus was herding his swine at the spot, and his herd was engulfed in the chasm down which Pluto had vanished with Persephone. Accordingly at the Thesmophoria it was customary, in memory of Eubuleus, to fling pigs into the "chasms of Demeter and Persephone." (These "chasms" may have been natural caverns or perhaps vaults. The scholiast speaks of them also as *adyta* and *megara*.[20]) In these chasms or adyta there were supposed to be serpents, which guarded the adyta and consumed most of the flesh of the pigs that were thrown in. The decayed remains of the flesh were afterwards fetched by women called "drawers" (*antletriai*), who, after observing rules of ceremonial purity for three days, descended into the caverns, and, frightening away the serpents by clapping their hands, brought up the remains and placed them on the altars.[21] Whoever got a portion of this decayed flesh and sowed it with the seed in the

[1] [Or, mother of a fair daughter, *i.e.* Persephone.] Schol. on Aristoph., *Thesmophoriazusae*, 80 and 585; Diog. Laërt., ix. 43; Hesychius, s.v. τριήμερος (the reading here is uncertain) and ἄνοδος; Alciphron, iii. 39; Athenaeus, vii. 307 f. Plutarch (*Vit. Demosth.*, 30) states that the Nesteia took place on the 16th of Pyanepsion, but in this he stands alone.

[2] Schol. on Aristoph., *Thesm.*, 80; Photius, *Lex.*, s.v. Θεσμοφορίων ἡμέραι δ′ (where Naber should not have altered the MS. reading δ′ into ιδ′); Hesychius, s.v. τρίτη Θεσμοφορίων.

[3] Schol. on Aristoph., *Thesm.*, 834.

[4] Photius, *Lex.*, s.v. στήνια; cf. Apollodorus, i. 5, 1.

[5] Plut., *Solon*, 8; for this passage probably refers to the Thesmophoria, the Cape Colias mentioned being near Halimus (see *Erläuternder Text* to the *Karten von Attika*, ii. 1 sq.). The Thesmophorion at Halimus is mentioned by Pausanias (i. 31, 1).

[6] Hesychius (s.v. ἄνοδος) and the Schol. on Arist., *Thesm.*, 585, suppose that the day was so called because the women ascended to the Thesmophorion, which (according to the scholiast) stood on a height. But no ancient writer mentions a procession from Halimus. For the name *Kathodos*, see Schol., *loc. cit.*; Photius, *Lex.*, s.v. Θεσμοφορίων ἡμέραι δ′. For the statement that at one part of the festival (commonly assumed, by the writers who accept the statement, to be the Anodos) the women carried on their heads the "books of the law," we have only the authority of the scholiast on Theocritus, iv. 25, who displays his ignorance by describing the women as virgins (see below), and saying that they went in procession to Eleusis. The statement may therefore be dismissed as an etymological fiction. Aristophanes, *Eccles.*, 222, is no evidence for the book-carrying.

[7] The Boeotian festival of Demeter, which was held at about the same time as the Athenian Thesmophoria, and at which the *megara* (see below) were opened, is distinctly stated by Plutarch (*De Is. et Osir.*, 69) to have been a mourning for the descent (Kathodos) of Persephone.

[8] Plut., *Dem.*, 30; Id., *De Is. et Osir.*, 69.

[9] [It was a day of holiday and rejoicing.]

[10] Hesychius, s.v. δίωγμα [perhaps the pursuit of Persephone]; Suïdas, s.v. χαλκιδικὸν δίωγμα [according to whom, the prayers of the women at the Thesmophoria caused the flight of the enemy to Chalcis]; Hesychius, s.v. ζημία. For flight and pursuit as parts of religious ceremonies, cf. Plutarch, *Quaest. Graec.*, 38, *Quaest. Rom.*, 63, *De Def. Orac.*, 15; Aelian, *Nat. An.*, xii. 34; Pausanias, i. 24, 4, viii. 53, 3; Diodorus, i. 91; Lobeck, *Aglaophamus* (1829), p. 676; Marquardt, *Staatsverwaltung*, 2nd ed. (1885), iii. 323.

[17] Aristoph., *Thesm.*, 80. The word τρίτη seems to mean the Nesteia, as the Schol. *ad l.* takes it. That the "middle day" was the Nesteia we know from Athenaeus, vii. 307 f.

[18] Xenophon, *Hellen.*, v. 2, 29; Plutarch, *Quaest. Gr.*, 31; Athenaeus, xiv. 647*a*.

[19] Polyaenus, v. 1, 1; Herodotus, vi. 16; Pausanias, x. 33, 11.

[20] C. T. Newton discovered in the sanctuary of Demeter and the Infernal Deities at Cnidus a chamber which may have been one of the *megara* referred to by the scholiast. It contained bones of pigs and marble figures of pigs. The chamber was not, however, originally subterranean. See Newton's *Discoveries at Halicarnassus* (1863), ii. p. 383, *Travels and Discoveries in the Levant* (1865), ii. p. 180 sq. According to Porphyry (*De Antro Nympharum*, 6) the Infernal Deities had *megara*, as the Olympian had temples, and the sacrificial pits of the former corresponded to the altars of the latter.

[21] Compare the functions of the two Arrephoroi at Athens (Paus., i. 27, 3). For serpents in connexion with Demeter, compare Strabo, ix. 1, 9.

ground was supposed thereby to secure a good crop.[1] The rest of the scholion is obscure, and perhaps corrupt, but the following seems to be the sense. The ceremony above described was called the arretophoria [the carrying of things which must not be spoken of], and was supposed to exercise the same quickening and fertilizing influence on men as on fields. Further, along with the pigs, sacred cakes made of dough, in the shape of serpents and of phalli, were cast into the caverns, to symbolize the productivity of the earth and of man. Branches of pines were thrown in[2] for a similar reason.

The custom described in this important scholion is clearly the same as that referred to by Clemens Alexandrinus (*Protrep.*, ch. ii.) [p. 14, ed. Potter] and Pausanias (ix. 8, 1). From the latter we learn that the pigs were sucking pigs, and from the former (if we adopt Lobeck's emendation μεγάροις ζῶντας for μεγαρίζοντες) that they were thrown in alive. From Pausanias we may further perhaps infer (though the passage is corrupt) that the remains of the pigs thrown down in one year were not fetched up till the same time next year (cf. Paus., x. 32, 14). The question remains, At what point of the Thesmophoria did the ceremony described by the scholiast on Lucian take place? Rohde thinks that it formed part of the ceremonies at Halimus, his chief ground being that Clemens (*Protrep.*, 34) and Arnobius (*Adv. Gentes*, v. 28) mention phalli in connexion with the "mysteries at Halimus"; but it is not certain that these mysteries were the Thesmophoria. The legend of Eubuleus seems to show that the ceremony commemorated the descent of Persephone to the nether world; and, if we are right in our interpretation of the name Kathodos as applied to the first day of the Thesmophoria proper, the ceremony described would naturally fall on that day. Further, if our interpretation of Pausanias is correct, the same day must have witnessed the descent of the living pigs and the ascent of the rotten pork of the previous year. Hence the day might be indifferently styled Kathodos or Anodos ("descent" or "ascent"); and so in fact it was.

It is usual to interpret Thesmophorus "lawgiver" and Thesmophoria "the feast of the lawgiver." But the Greek for "lawgiver" is not Thesmophorus but Thesmothetes (or Nomothetes, when *nomos* displaced *thesmos* in the sense of "law"). If we compare such names of festivals as Oschophoria, Lampadephoria, Hydrophoria, Scirophoria ("the carryings of grapes, of torches, of water, of umbrellas") with the corresponding Oschophorus, Lampadephorus, Hydrophorus, also Thallophorus and Kanephorus, we can scarcely help concluding that Thesmophoria must originally have meant in the literal and physical sense the carrying of the *thesmoi*, and Thesmophorus the person who so carried them; and, in view of the ceremony disclosed by the scholiast on Lucian (compared with the analogous ceremony observed by the Arrephoroi at Athens), we are strongly tempted to suppose that the women whom he calls Antletriai may have been also known, at one time or other, as Thesmophoroi, and that the *thesmoi* were the sacra which they carried and deposited on the altar. The word would then be used in its literal sense, "that which is set down." How the name Thesmophorus should have been transferred to the goddess from her ministers is of course a difficulty, which is hardly disposed of by pointing to the epithets Amallophorus ("sheaf-bearing") and Melophorus ("apple-bearing"), which were applied to men as well as to the goddess.

As to the origin of the Thesmophoria, Herodotus (ii. 171) asserts that they were introduced into Greece from Egypt by the daughters of Danaus; while, according to Plutarch (*Fragments*, p. 55, ed. Dübner [*Frag. Incerta*, 84]), the feast was introduced into Athens by Orpheus the Odrysian. From these statements we can only infer the similarity of the Thesmophoria to the Orphic rites and to the Egyptian representation of the sufferings of Osiris, in connexion with which Plutarch mentions them. The Thesmophoria would thus form one of that class of rites, widely spread in Western Asia and in Europe, in which the main feature appears to be a lamentation for the annual decay of vegetation or a rejoicing at its revival. This seems to have been the root, *e.g.*, of the lamentations for Adonis and Attis. See W. Mannhardt, *Antike Wald- und Feld-Kulte*, p. 264 sq.

On the Thesmophoria, see Meursius, *Graecia Feriata*, p. 151 sq.; L. Preller, *Demeter und Persephone* (1837), p. 335 sq., *Griech. Myth.*, [3], i. p. 639 sq.; Fritzsche's ed. of the *Thesmophoriazusae* (1838), p. 577 sq.; Aug. Mommsen, *Heortologie* (1864), p. 287 sq.; *Rheinisches Museum*, xxv. (1870), p. 548; *Gazette Archéologique* (1880), p. 17; Andrew Lang, "Demeter and the Pig," in *Nineteenth Century*, April 1887; J. G. Frazer, *Golden Bough*, ii. 44; J. E. Lenormant (on CERES) in Daremberg and Saglio, *Dictionnaire des Antiquités*.

(J. G. FR.; X.)

[1] This, as Andrew Lang has pointed out, resembles the Khond custom of burying the flesh of the human victim in the fields to fertilize them. The human victim was with the Khonds, like the pig with the Greeks, a sacrifice to the Earth goddess. See *Memorials of Service in India . . . of Major S. C. Macpherson*, ed. William Macpherson (1865), p. 129.

[2] Reading ἐμβάλλουσι, with Rohde, for λαμβάνουσι. Compare the custom of Miletus *supra*. The pine-tree played an important part in the worship of Cybele. Cf. Marquardt, *Staatsverwaltung* (1885), iii. 371.

THESPIAE, an ancient Greek city of Boeotia. It stood on level ground commanded by the low range of hills which runs eastward from the foot of Mount Helicon to Thebes. The deity most worshipped at Thespiae, according to Pausanias, was Eros, whose primitive image was an unwrought stone. The town contained many works of art, among them the Eros of Praxiteles, dedicated by Phryne in her native place; it was one of the most famous statues in the ancient world, and drew crowds of people to Thespiae. It was carried off to Rome by Caligula, restored by Claudius, and again carried off by Nero. There was also a bronze statue of Eros by Lysippus. The Thespians also worshipped the Muses, and celebrated a festival in their honour in the sacred grove on Mount Helicon. Remains of what was probably the ancient citadel are still to be seen, consisting of an oblong or oval line of fortification, solidly and regularly built. The adjacent ground to the east and south is covered with foundations, bearing witness to the extent of the ancient city. The neighbouring village Eremokastro, on higher ground, was thought by Ulrichs to be probably the site of the ancient Ceressus. In 1882 there were discovered, about 1200 yds. east of Eremokastro, on the road to Arkopodi (Leuctra), the remains of a *polyandrion*, including a colossal stone lion. The tomb dates from the 5th century B.C., and is probably that of the Thespians who fell at Plataea, for those who fell at Thermopylae were buried on the field.

History.—Thespiae figures chiefly in history as an enemy of Thebes, whose centralizing policy it had all the more to fear because of the proximity of the two towns. During the Persian invasion of 480 B.C. it stood almost alone among Boeotian cities in rejecting the example of treason set by the Thebans, and served the national cause with splendid devotion. Seven hundred Thespians accompanied Leonidas to Thermopylae and of their own free will shared his last stand and destruction. The remaining inhabitants, after seeing their city burnt down by Xerxes, furnished a force of 1800 men to the confederate Greek army at Plataea. In 424 B.C. the contingent which the Thespians had been compelled to furnish sustained heavy losses at Delium, and in the next year the Thebans took advantage of this temporary enfeeblement to accuse their neighbours of friendship towards Athens and to dismantle their walls. In 414 they interfered again to suppress a democratic rising. In the Corinthian war Thespiae sided with Sparta, and between 379 and 372 repeatedly served the Spartans as a base against Thebes. In the latter year they were reduced by the Thebans and compelled to send a contingent to Leuctra (371). It was probably shortly after this battle that the Thebans used their new predominance to destroy Thespiae and drive its people into exile. The town was rebuilt at some later time. In 171 B.C., true to its policy of opposing Thebes, it sought the friendship of Rome. It is subsequently mentioned by Strabo as a place of some size, and by Pliny as a free city.

THESPIS (6th cent. B.C.), Greek poet, of Icaria, in Attica, generally considered the inventor of tragedy, flourished in the time of the Peisistratidae. According to Diogenes Laërtius (iii. 56), he introduced for the first time in the old dithyrambic choruses a person distinct from the chorus, who conversed with the leader, and was hence called ὑποκριτής ("answerer").[3]

[3] According to another explanation, he was so called from repeating the words of another—the poet or composer.

His claim to be regarded as the inventor of tragedy in the true sense of the term depends upon the extent to which this person was really an "actor" (see DRAMA). Suïdas gives the titles (of doubtful authenticity) of several of his plays (not confined to the legends of Dionysus, but embracing the whole body of heroic legends), but the fragments quoted in various writers as from Thespis are probably forgeries by Heracleides of Pontus. The statement of Horace (*Ars Poetica*, 276) that Thespis went round Attica with a cart, on which his plays were acted, is due to confusion between the origin of tragedy and comedy, and a reminiscence of the scurrilous jests which it was customary to utter from a waggon (σκώμματα ἐξ ἁμάξης) at certain religious festivals. A. and M. Croiset (*History of Greek Literature*, Eng. tr., 1904), who attach more importance to the part played by Thespis in the development of tragedy, accept the testimony of Horace. According to them, Thespis, actor and manager, transported his apparatus on a cart to the deme in which he intended to produce his drama, formed and trained a chorus, and gave a representation in public.

See DRAMA; and W. Christ, *Griechische Litteraturgeschichte* (1898).

THESSALONIANS, EPISTLES TO THE, two books of the New Testament. The Christian community in Thessalonica (mod. Salonica) was founded by Paul, Silvanus and Timothy, shortly before the visit to Athens and Corinth. The Gospel preached covered not only the general Christian convictions as to monotheism, belief in Jesus as Messiah Lord, and the impending judgment, but also the specifically Pauline doctrine of the indwelling Christ or Spirit, the earnest of acquittal at the Day of the Lord and of life with Christ for ever. It is the same Gospel as that preached in Galatia, in spite of the fact that the word "justification" does not appear in the Thessalonian letters (cf. 2 Thess. i. 11 f.). The converts, mainly Gentiles and chiefly manual labourers (many of whom, according to the episodical narrative of Acts xvii., had been already attached more or less loosely to Judaism), suffered persecution from the beginning at the hands of their fellow-countrymen. Some of them, moreover, owing partly to this persecution, but mainly to the belief that the Lord was soon to return, gave up work, thus creating most of the difficulties with which Paul, in these letters, has to cope. Forced to leave Thessalonica after a brief sojourn (how long is uncertain), Paul hastened to Athens, from which place he sent Timothy back to Thessalonica, being himself unable to go, much as he longed to see his converts. From Athens, Paul went on to Corinth, where Timothy joined him, bringing good news about the Thessalonian converts, especially about their endurance under affliction, and bringing likewise, as Rendel Harris has suggested, a letter from the leaders of the church. The report was, however, not wholly favourable. The sudden departure of Paul, and his failure to return, had been misinterpreted. Some were insinuating that Paul had preached with intent to deceive and as a pretext to cover impure designs (1 Thess. ii. 5); some, perhaps the same people, disregarding Paul's injunction (2 Thess. iii. 10), had remained idle, had fallen into drunken habits (1 Thess. v. 7), had been tempted to revert to the impure worship of the heathen gods (1 Thess. iv. 3 ff.), and, in their lack of funds, had demanded, speaking in the spirit (cf. *Didachē* xi. 12), money from the church officers, thus disturbing the peace of the church, and causing the soberer minds to question the validity of spiritual gifts (1 Thess. iv. 11 ff., v. 12 ff.).

First Epistle.

Paul's reply, the First Epistle to the Thessalonians, written from Corinth in A.D. 53 or 48, is as tactful as Philemon and as personal as Galatians. In the first three chapters, he reviews his relation to the church from the beginning, commending highly the reception accorded to the Gospel and its messengers, and meeting the insinuations already alluded to by reminding the readers that, although as an apostle he was entitled not only to special respect but to an honorarium, yet he earned his own living and loved them as a father. As to his failure to return, he explained that it was not his own fault. He wanted to go back but Satan hindered him. Even now, as he writes, he is praying that he may soon see them face to face. After the prayer, he takes up the points in which they had shown want of faith. To those who are tempted by the heathen worship, he points out that Christian consecration is something ethical, to be won only in the power of the consecrating Spirit. Respect for one's wife is an antidote to this enticement, and marriage with pure motives a safeguard against adultery. Passing on to other points, he urges that there would be no schism in love of the brethren, if the idlers would work and mind their own business (1 Thess. iv. 1–12). There is no advantage at the Parousia of the living over the dead, for both simultaneously will meet the Lord. The desire for more accurate information about times and seasons is unnecessary, for their present knowledge is accurate enough, viz. that the day is to come suddenly and it is a day of destruction for the wicked. The main thing for them is to be prepared for that day (1 Thess. iv. 13–v. 11). With the specific situation still in mind, he adds his final injunctions. Respect your presiding officers, purposely called "the labourers," and let there be peace. Warn the idlers, encourage those who are impatient of the Parousia, and cling to those tempted by the heathen worship. In spite of the temptation to avenge your persecutors, be patient with them, return good for evil, exemplifying to all what is the Christian good. In spite of affliction, let there be joy, prayer and thanksgiving (1 Thess. v. 14–18). The charismata are to be respected, and at the same time tested (*ibid.* 19–22). A prayer for complete consecration, a charge that all should hear the letter read (apparently the leaders were tempted to neglect the idlers and the idlers had threatened not to listen to any epistolary communication from Paul), and a benediction bring the letter to an end (*ibid.* 23–28).

Such a letter, dominated as it is by the spirit of the Paul we know and fitting nicely the recoverable situation, is unquestionably genuine, and few there be who deny it.

What effect this letter had, it is impossible fully to say. Apparently, it did not quell the excitement for which the idlers were largely responsible. Paul's discussion of the relation of dead and living at the Parousia seemed insufficient. His refusal to go further into times and seasons than the statement "the day comes as a thief in the night," is made the point of departure for the idlers to assert, on the basis of alleged spiritual utterances, corroborated, to the dismay of the leaders, by a reference to an anonymous letter reckoned to the account of Paul, that "the day is present." The troubled leaders send post-haste a letter to Corinth stating the situation and asking definite opinions as to the Parousia and the assembling of the saints. Paul is grievously disturbed, both because the first letter, in his judgment, was clear, and because of the association of his authority with the anonymous letter. Only a short interval has elapsed, to be reckoned in weeks, when Paul, with the first letter distinctly in mind and with a vivid recollection of his oral teaching on mooted points, hastens with Silvanus and Timothy to write the Second Epistle.

Second Epistle.

In one long sentence of prayer and thanksgiving (2 Thess. i. 3–12), he insists tactfully that their religious-ethical growth makes it his bounden duty to thank God, in spite of their written demurrer, compels him indeed of his own motion to boast of their faith and endurance, qualities which are evidence of the Divine purpose to account them worthy of the kingdom for which they, as they wrote, as well as he, are suffering. Suddenly remembering a Pharisaic Psalm, not unlike in purport to one of the Psalms of Solomon, and admirably adapted to his present purpose, namely, of contrasting the fate of the wicked with that of the righteous at the Parousia, he quotes it, making a few Christian touches in his own style (2 Thess. i. 6–10). Whereupon he prays, as they too prayed in their letter, that God would deem them worthy of the calling, and ensure them of the acquittal at the last day, by giving them in the power of the Spirit that present life in the Spirit which guarantees the future life in Christ. Then, disregarding the request for more information about the assembling, of which, he thinks, he had spoken sufficiently in his first letter, he addresses himself to the other question of the "when" of the Parousia, supplementing what was said in the first letter, but adding nothing to what he had already said orally in their presence, and stoutly disclaiming all authority whatever for the statement "the day is present." Briefly and allusively, in language which has nothing specifically Christian in it and in style similar to the first chapter (verses 6–10), he recalls the familiar story. The day does not come until the final revolt in heaven and until the lawless one (the man of lawlessness, the son of Perdition) is revealed, which revelation cannot happen, until the controlling or restraining thing or person is removed. Then, however, the tool of Satan will appear, but the Lord will destroy him with the breath of his mouth and annihilate him with the majesty of his presence (2 Thess. ii. 1–12). Following the formal order of the First Epistle, he again thanks God that his converts are chosen to salvation and prays that they may have strength and obey his orders oral or written. Even with a "finally," as in the first letter, he is not quite through, for the second point of the letter remains to be treated —the idlers. These, he says, must remember both his example (he was never guilty of begging) and his precept ("if any man will not work let him not eat"). They must work quietly and eat their own food. Those who refuse to heed his written orders are to be noted. The test of the genuineness of his letters is his autograph greeting (2 Thess. ii. 13–iii. 18).

The letter meets the known situation excellently. The new material, compared with the First Epistle, is the supplementary discussion of the time of the Parousia (2 Thess. ii. 1 ff.) and the fuller treatment of the idlers (2 Thess. iii. 1 ff.), the points about which the leaders sought advice. The style is Pauline even in the adaptation of Jewish apocalyptic material to Christian purposes. Indeed, the outline of the letter is strikingly similar to that of the First Epistle, and many phrases hold over. At the same time there is a freedom of style suggesting not the imitator but the same author. And above all, especially in the treatment of the idlers, the letter reveals a knowledge of the situation which is even more explicit than that of the First Epistle. On such grounds, together with the excellent external attestation, it is probable, as recent writers hold (*e.g.* Zahn, Wohlenberg, Harnack, Jülicher, Findlay, Askwith, Charles, Bacon, McGiffert, Moffatt, Milligan, *et al.*), that the letter is Paul's.

The objection to the Pauline authorship felt by the Tübingen school may, for brevity's sake, be here disregarded. The modern difficulties, expressed mainly by recent German scholars (*e.g.* Wrede and Holtzmann and others), centre not in the un-Pauline language or in the lack of the personal element, but in the eschatology and the over-Pauline character of the language. As to the first objection, the eschatology, it is replied that the section ii. 1–12 is scarcely an interpolation, since it is one of the two main reasons for the letter; that the material of the section is a distinct allusion to, if not a direct quotation of, a definite bit of Jewish apocalyptic, even if we do not connect it, as Bousset does, with a so-called Antichrist legend; that the alleged inconsistency between the eschatology of the First and the Second Epistle does not exist, for in the first letter Paul says not that the day is present, but that the day, when it comes, comes suddenly "as a thief in the night," while in the second letter he expressly denies the statement attributed to him, namely, that "the day is present." Wrede, in his brilliant argument against the genuineness of the letter (*Die Echtheit des zweiten Thessalonicherbriefes*, 1903), inclines to admit that the argument from eschatology is secondary.

As to the second objection, the over-Pauline character of the letter, an objection used with rigour by McGiffert (whose article on these letters in the *Ency. Biblica* is the most satisfactory discussion known to the present writer), and renewed independently by Wrede, it is to be admitted that the similarity of the second to the first letter is striking, particularly in the formal arrangement of the material. At the same time, the differences, both in arrangement and in the content of the reminiscences, are not to be overlooked, as McGiffert and after him Wernle (*Gött. gel. Anz.*, 1905, pp. 347–52) have both rightly maintained. Again there should be no disparagement of the new material such as is to be found in Holtzmann's acute discussion (*Z. N. T. W.*, 1901, pp. 97–108). On the whole, the perplexing situation seems to be met on the assumption that Paul writes the Second Epistle either with a letter from Thessalonica before him, which itself suggested the main points of his own epistle, or with a copy or a summary of that epistle before him (cf. Zahn and McGiffert).

The alternative is forgery, as Holtzmann, Wrede and Hollmann (*Z. N. T. W.*, 1904, pp. 28–38) actually hold. The difficulty with this hypothesis is that it does not explain so many facts as the hypothesis of Pauline authorship. As it is improbable that the forger would write during the lifetime of Paul, the date has to be put either shortly after his death, or with Wrede at the end of the century. But this late date creates the insuperable difficulty that iii. 1 ff. gives a more explicit account of the original situation in Thessalonica touching the idlers than does the First Epistle. The purpose moreover of the forgery could not be to discredit the First Epistle as un-Pauline, for the alleged trouble is that the Second Epistle is too Pauline. Hence the purpose is to correct the statements of the First Epistle. If, however, there is no inconsistency between the two letters on the score of eschatology, what is the forger's purpose? The teaching about premonitory signs is not new to Thessalonica, but is assumed as known, hence the allusive character of the second chapter. The statements in ii. 2 and iii. 17 are easily explicable on the hypothesis that the idlers found an anonymous letter and attributed it to Paul, especially when they thought, perhaps in good faith, that the Spirit had indicated that the day is present. Finally, the forger handles Paul's style with miraculous knowledge, not only reproducing phrases from the first letter, but knowing how to amend them to present purposes with singular naturalness. When it comes to putting Christian touches to a Jewish fragment, the touches turn out to be uniquely Pauline, although they are not obviously Pauline (*e.g.* i. 6–10 "εἴπερ," "obey the Gospel," "was believed"). And even with the thought of Paul, he is curiously at home. So certain is he of the substance of Paul's thought, that he can reproduce it in a concise sentence without recourse to the word "justification" (*e.g.* i. 11). On the whole, then, the situation created by the literary relation of the two letters is best met by the hypothesis that Paul is the author of the Second Epistle.

In addition to the literature mentioned under Colossians, Epistle to the, and the special literature already named in this article, reference should be made to the commentaries on these letters by Ellicott (1858), Jowett (1859), Eadie (1877), Hutchinson (1883), Lightfoot (Notes, 1895), Drummond (1899), Findlay (1892 and 1904), Milligan (1908), and Moffatt (1908); and by Schmidt (1885), Zimmer (1885–93), Schmiedel (1892), Zöckler (1894), Bornemann (1894), B. Weiss (1896) and Wohlenberg (1903).

(J. E. F.)

THESSALY, a district of northern Greece, between Macedonia and the more purely Hellenic countries towards the south, and between the upland region of Epirus and the Aegean Sea. It forms an irregular square, extending for about sixty miles in each direction, and this area, which is for the most part level, is enclosed by well-marked boundaries—by the Cambunian Mountains on the north, and by Othrys on the south, while on its western side runs the massive chain of Pindus, which is the backbone of this part of Greece, and towards the east Ossa and Pelion stand in a continuous line; at the north-eastern angle is Olympus, the keystone of the whole mountain system. The elevation of some of the summits in these ranges is considerable, for three of the peaks of Pindus are over 5000 ft., and Olympus, Ossa and Pelion reach respectively the height of 9790, 6398 and 5350 ft. The country that is contained within these limits is drained by a single river, the Peneius, which, together with the water of its numerous confluents, passes into the sea through the Vale of Tempe.

On the north side of Thessaly there was an important pass from Petra in Pieria by the western side of Olympus, debouching on the plain northward of Larissa; it was by this that Xerxes entered, and we learn from Herodotus (vii. 173) that, when the Greeks discovered the existence of this passage, they gave up all thoughts of defending Tempe. On the side of Epirus the main line of communication passed over that part of Pindus which was called Mount Lacmon, and descended the upper valley of the Peneius to Aeginium in the north-west angle of Thessaly. This was the route by which Julius Caesar arrived before the battle of Pharsalia. Another pass through the Pindus chain was that of Gomphi, farther south, by means of which there was communication with the Ambracian Gulf. The great southern pass was that of Coela, which crosses Mount Othrys nearly opposite Thermopylae. These Thessalian passes were of the utmost importance to southern Greece, as commanding the approaches to that part of the country.

Though Thessaly is the most level district of Greece, it does not present a uniform unbroken surface, but is composed of a number of sections which open out into one another, divided by ranges of hills. The principal of these were called Upper and Lower Thessaly, the former comprising the western and south-western part, which contains the higher course of the Peneius and all those of its tributaries that flow from the south—the Enipeus, the Apidanus, the Onochonus and the Pamisus; while the latter, which reaches eastward to the foot of Ossa and Pelion, is inundated in parts at certain seasons of the year by the Peneius, the flood-water from which forms the lake Nessonis, and, when that is full, escapes again and pours itself into the lake of Boebe. The chief city of the latter of these districts was Larissa; and the two were separated from one another by a long spur, which runs southwards from the Cambunian Mountains on the western side of that city. Again, when Thessaly, is entered from the south by the pass of Coela, another plain, containing a small lake, which was formerly called Xynias, intervenes, and a line of low hills has to be crossed before the town of Thaumaki is reached, which from its commanding position overlooks the whole of the upper plain. The view from this point has been described by Livy in the following remarkable passage:—"When the traveller, in passing through the rugged districts of Thessaly, where the roads are entangled in the windings of the valleys, arrives at this city, on a sudden an immense level expanse, resembling a vast sea, is outspread before him in such a manner that the eye cannot easily reach the limit of the plains extended beneath" (xxxii. 4). To the north-east of this, where a portion of the great plain begins to run up into the mountains, the Plain of Pharsalia is formed, which is intersected by the river Enipeus; and still farther in the same direction is the scene of another great battle, Cynoscephalae. Thessaly was further subdivided into four districts, of which Pelasgiotis embraced the lower plain of the Peneius, and Hestiaeotis and Thessaliotis respectively the northern and the southern portions of the upper plain; while the fourth, Phthiotis, which lies towards the south-east, was geographically distinct from the rest of the country, being separated from it by a watershed. The determining feature of this is the Pagasaeus Sinus (Gulf of Volo), a landlocked basin, extending from Pagasae at its head to Aphetae at its narrow outlet, where the chain of Pelion, turning at right angles to its axis at the end of Magnesia, throws out a projecting line of broken ridges, while on the opposite side rise the heights of Othrys. In the heroic age this district was of great importance. It was the birthplace of Greek navigation, for this seems to be implied in the story of the Argonauts, who started from this neighbourhood in quest of the golden fleece. From it the great Achilles came, and, according to Thucydides (i. 3), it was the early home of the Hellenic race. The site of Iolcus, the centre of so many poetic legends, is at no great distance from the modern Volo. Near that town also, at a later period, Demetrius Poliorcetes founded the city of Demetrias, which was called by Philip V. of Macedon one of the three fetters of Greece, Chalcis and Corinth being the other two.

The history of Thessaly is closely connected with its geography. The fertility of the land offered a temptation to invaders, and was thus the primary cause of the early migrations. It was this motive which first induced the Thessalians to leave their home in Epirus and descend into this district, and from this movement arose the expulsion of the Boeotians from Arne, and their settlement in the country subsequently called Boeotia; while another wave of the same tide drove the Dorians also southward, whose migrations changed the face of the Peloponnese. Again, this rich soil was the natural home of a powerful aristocracy, such as the families of the Aleuadae of Larissa and the Scopadae of Crannon; and the absence of elevated positions was unfavourable to the foundation of cities, which might have fostered the spirit of freedom and democracy. The plains, also, were suited to the breeding of horses, and consequently the force in which the Thessalian nation was strong was cavalry, a kind of troops which has usually been associated with oligarchy. The wealth and the semi-Hellenic character of the people—for in race, as in geographical position, the Thessalians held an intermediate place between the non-Hellenic Macedonians and the Greeks of pure blood—caused them to be wanting in patriotism, so that at the time of the Persian wars we find the Aleuadae making common cause with the enemies of Greece. When they were united they were a formidable power, but, like other half-organized communities, they seldom combined for long together, and consequently they influenced but little the fortunes of the Greeks.

For several centuries during the middle ages Rumanian immigrants formed so large a part of the population of Thessaly that that district was called by the Byzantine writers Great Wallachia (Μεγάλη Βλαχία): the Jewish traveller, Benjamin of Tudela, who passed through the country in the latter half of the 12th century, describes them as then occupying it. At the present day only a few colonies of that race remain, the principal of which are found on the western side of Olympus and in some of the gorges of Pindus. The Turkish inhabitants were settled in the larger towns, and here and there in the country districts, the most important colony being those called Koniarates, who were brought from Konia in Asia Minor shortly before the taking of Constantinople, and planted under the south-west angle of Olympus. The Greeks, however, form the vast majority of the population, so much so that, even while the country belonged to the Ottomans, Greek was employed as the official language. In accordance with the provisions of the Berlin treaty, Thessaly was ceded to the Greeks by the Porte in 1881, and became a portion of the Hellenic kingdom. Since that time the prosperity of the province has greatly increased. The port of Volo, which is almost the only outlet of the trade of the whole district, has become an important town of 23,000 inhabitants, and daily communication by steamers now exists between it and Athens. The interior of the country has also been opened up by means of railways. One line runs north-westwards from Volo by way of Velestino (the ancient Pherae) to Larissa, which is situated on the Salambria (Peneius), and has a population of 18,000 souls, including 2000 Jews. The Greeks, Turks and Jews here occupy different quarters of the city, but most of the Turkish inhabitants have now quitted the country, so that only four of the numerous mosques remain in use. From Velestino another line branches off to the west by Phersala (Pharsalos), Domokos (Thaumaki), Karditsa, and Trikkala (Trika), to Kalabaka (Aeginium), where the upper valley of the Salambria is entered. In the neighbourhood of the last-named place, where the Cambunian chain of mountains descends in steep precipices to the plain, are the Meteora ("mid-air") monasteries (see METEORA).

THETFORD, a market town and municipal borough of England, mostly in the south-western parliamentary division of Norfolk, but partly in the Stowmarket division of Suffolk, 91 m. N.N.E. from London by the Great Eastern railway. Pop. (1901) 4613. The town lies in a level, fertile country at the junction of the river Thet with the Little Ouse. In the time of Edward III. the town had twenty churches and eight monasteries. There are now three churches—St Peter's, St Cuthbert's and St Mary's—principally of Perpendicular flint work; of these St Mary's, on the Suffolk side, is the largest. There are a few monastic remains, the chief being two gate-houses. The most important relic of antiquity is the Castle Hill, a mound 1000 ft. in circumference and 100 ft. in height. The grammar school was founded in 1610. In King Street is the mansion-house occupied as a hunting-lodge by Queen Elizabeth and James I. The chief public buildings are a gild hall and a mechanics' institute; there are several charities. Brewing and tanning are carried on; and there are also manure and chemical works, brick- and lime-kilns, flour-mills and agricultural implement works, engineering works and iron foundries. The Little Ouse is navigable for barges down to the Great Ouse. Thetford is a suffragan bishopric in the diocese of Norwich. The town is governed by a mayor, 4 aldermen, and 12 councillors. Area, 7096 acres.

Early antiquaries identified Thetford (Theodford, Tetford, Tefford) with Sitomagus, but modern research shows that there is no conclusive evidence of a permanent settlement before the coming of the Angles. Tradition tells that Uffa, who probably threw up the earthworks called the Castle Hill, established the capital of East Anglia here about 575. Thetford owned a royal mint in the 9th century and was a flourishing town when the Conqueror acquired it. Richard I. granted it to Hamelin, Earl Warenne, and when his heirs failed, it merged in the duchy of Lancaster and so in the crown. About 1290 its principal officers were a mayor and coroner, afterwards assisted by eight burgesses, whom Henry VIII. increased to ten. The town, never very prosperous since the Conquest, had then fallen into great decay, but the petitions of the burgesses for a charter were not heeded till 1573 when Elizabeth incorporated it under a mayor and common council. This charter, restored in 1692 after its surrender to Charles II., remained in force till 1835 when the borough was re-constituted. Thetford returned two members to parliament from 1529 till its disfranchisement in 1868. Its Saturday market, which certainly existed in the 13th century, was granted by the charter of 1573 and also a Magdalen fair (the 22nd of July). Fisheries were important in the 13th century.

See A. L. Hunt, *Capital of East Anglia* (1870); T. Martin, *History of Thetford* (1779).

THETIS, in Greek mythology, daughter of Nereus, wife of Peleus and mother of Achilles. The chief of the fifty Nereids, she dwelt in the depths of the sea with her father and sisters. When Dionysus leaped into the sea to escape from the pursuit of Lycurgus, king of the Thracian Edones, and Hephaestus was flung out of heaven by Zeus, both were kindly received by Thetis. Again, when Hera, Athena and Poseidon threatened to bind Zeus in chains, she sent the giant Aegaeon, who delivered him out of their hands. She was married against her will to Peleus (*q.v.*; see also ACHILLES). Thetis is used by Latin poets simply for the sea.

THEURIET, CLAUDE ADHÉMAR ANDRÉ (1833–1907), French poet and novelist, was born at Marly-le-Roi (Seine et Oise) on the 8th of October 1833, and was educated at Bar-le-Duc in his mother's province of Lorraine. He studied law in Paris and entered the public service, attaining the rank of *chef de bureau* before his retirement in 1886. He published in 1867 the *Chemin des bois*, a volume of poems, many of which had already appeared in the *Revue des Deux Mondes; Le bleu et le noir, poèmes de la vie réelle* (1874), *Nos oiseaux* (1886), and other volumes followed. M. Theuriet gives natural, simple pictures of rustic and especially of woodland life, and Théophile Gautier compared him to Jaques in the forest of Arden. The best of his novels are those that deal with provincial and country life. Among them are: *Le mariage de Gérard* (1875); *Raymonde* (1877); *Le fils Maugars* (1879); *La maison des deux Barbeaux* (1879); *Sauvageonne* (1880); *Reine des bois* (1890); *Villa tranquille* (1899); *Le manuscrit du chanoine* (1902). Theuriet received in 1890 the *prix Vitet* from the French Academy, of which he became a member in 1896. He died on the 23rd of April 1907, and was succeeded at the Academy by M. Jean Richepin.

See Emm. Besson, *André Theuriet* (1890).

THÉVENOT, JEAN DE (1633–1667), French traveller in the East, was born in Paris on the 16th of June 1633, and received his education in the college of Navarre. The perusal of works of travel moved him to go abroad, and his circumstances permitted him to please himself. Leaving France in 1652, he first visited England, Holland, Germany and Italy, and at Rome he fell in with D'Herbelot, who invited him to be his companion in a projected voyage to the Levant. D'Herbelot was detained by private affairs, but Thévenot sailed from Rome in May 1655, and, after vainly waiting five months at Malta, took passage for Constantinople alone. He remained in Constantinople till the end of the following August, and then proceeded by Smyrna and the Greek islands to Egypt, landing at Alexandria on New Year's Day, 1657. He was a year in Egypt, then visited Sinai, and, returning to Cairo, joined the Lent pilgrim caravan to Jerusalem. He visited the chief places of pilgrimage in Palestine, and, after being twice taken by corsairs, got back to Damietta by sea, and was again in Cairo in time to view the opening of the canal on the rise of the Nile (on the 14th of August 1658). In January 1659 he sailed from Alexandria in an English ship, taking Goletta and Tunis on the way, and, after a sharp engagement with Spanish corsairs, one of which fell a prize to the English merchantman, reached Leghorn on the 12th of April. He now spent four years at home in studies useful to a traveller, and in November 1663 again sailed for the East, calling at Alexandria and landing at Sidon, whence he proceeded by land to Damascus, Aleppo, and then through Mesopotamia to Mosul, Bagdad and Mendeli. Here he entered Persia (the 27th of August, 1664), proceeding by Kermanshah and Hamadan to Isfahan, where he spent five months (October 1664–February 1665), and then joining company with the merchant Tavernier, proceeded by Shiraz and Lar to Bander-Abbasi, in the hope of finding a passage to India. This was difficult, because of the opposition of the Dutch, and though Tavernier was able to proceed, Thévenot found it prudent to return to Shiraz, and, having visited the ruins of Persepolis, made his way to Basra and sailed for India on the 6th of November 1665, in the ship "Hopewell," arriving at the port of Surat on the 10th of January 1666. He was in India for thirteen months, and crossed the country by Golconda to Masulipatam, returning overland to Surat, from which he sailed to Bander-Abbasi and went up to Shiraz. He passed the summer of 1667 at Isfahan, disabled by an accidental pistol-shot, and in October started for Tabriz, but died on the way at Miyana on the 28th of November 1667.

Thévenot was an accomplished linguist, skilled in Turkish, Arabic and Persian, and a curious and diligent observer. He was also well skilled in the natural sciences, especially in botany, for which he made large collections in India. His personal character was admirable, and his writings are still esteemed, though it has been justly observed that, unlike Chardin, he saw only the outside of Eastern life. The account of his first journey was published at Paris in 1665; it forms the first part of his collected *Voyages*. The licence is dated December 1663, and the preface shows that Thévenot himself arranged it for publication before leaving on his second voyage. The second and third parts were posthumously published from his journals in 1674 and 1684 (all 4to). A collected edition appeared at Paris in 1689, and a second in 12mo at Amsterdam in 1727 (5 vols.). There is an indifferent English translation by A. Lovell (fol., London, 1687).

THIAZINES, in organic chemistry, a series of cyclic compounds containing a ring system of four carbon atoms, one nitrogen and one sulphur atom. These may be grouped in three ways, giving the following skeletal structures:—

$$\text{(I.)}\ \begin{array}{c}C\cdot C\cdot N\\ \dot{C}\cdot C\cdot \dot{S}\end{array}\ ,\qquad \text{(II.)}\ \begin{array}{c}C\cdot N\cdot C\\ \dot{C}\cdot C\cdot \dot{S}\end{array}\ ,\qquad \text{(III.)}\ \begin{array}{c}C\cdot N\cdot C\\ \dot{C}\cdot S\cdot \dot{C}\end{array}$$

Members of the first series have not as yet been isolated. Derivatives of the second type have been obtained by A. Luchmann (*Ber.* 1896, 29, p. 1429) by condensing γ-chlorbutylamine with carbon bisulphide or with mustard oils in the presence of caustic alkali; by M. Kahan (*ibid.*, 1897, 30, p. 1321) on condensing bromhexylamine hydrobromide with thiobenzamide:

$$\begin{array}{l}\quad CH_2\cdot CH(CH_3)Br\\ (CH_3)_2\dot{C}\cdot NH_2\end{array} + \begin{array}{l}\quad HS\\ HN:\dot{C}\cdot C_6H_5\end{array} \rightarrow \begin{array}{l}\quad CH_2\cdot CH(CH_3)\cdot S\\ (CH_3)_2\dot{C}-N=\!=\!=\!=\dot{C}\cdot C_6H_5\end{array}$$

Benzothiazines are obtained from ortho-aminobenzyl halides and thio-amides:

$$C_6H_4\left\langle\begin{array}{l}CH_2Br\\ NH_2\end{array}\right. + H_2N\cdot CS\cdot CH_3 \rightarrow C_6H_4\left\langle\begin{array}{l}CH_2\cdot S\\ \quad\ \ \ |\\ N=\!=C\cdot CH_3.\end{array}\right.$$

The most important thiazines are those derived from class III., thiodiphenylamine, $C_6H_4\left\langle\begin{array}{c}N\\ S\end{array}\right\rangle C_6H_4$, being the parent substance of the methylene blue series of dyestuffs. Thiodiphenylamine is obtained synthetically by heating sulphur with diphenylamine or by the condensation of ortho-aminothiophenol with pyrocatechin. It is a compound of neutral reaction. The first known dyestuff of this series was Lauth's violet, which was prepared by oxidizing paraphenylene diamine in acid solution in the presence of sulphur. By using dimethyl paraphenylene diamine in place of the simple diamine, methylene blue is obtained. The relationship of these substances to thiodiphenylamine was shown by A. Bernthsen, who, by nitration of thiodiphenylamine, cbtained a dinitro-compound which on reduction was converted into the corresponding di-amino-derivative and this on oxidation yielded Lauth's violet.

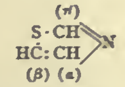
$$C_6H_4\left\langle{NH \atop S}\right\rangle C_6H_4 \rightarrow NO_2\cdot C_6H_3\left\langle{NH \atop S}\right\rangle C_6H_3\cdot NO_2 \rightarrow NH_2\cdot C_6H_3\left\langle{NH \atop S}\right\rangle C_6H_3\cdot NH_2 \rightarrow HN:C_6H_3\left\langle\!\left\langle{N \atop S}\right\rangle\right. C_6H_3\cdot NH_2$$

Methylene blue is the most important of all blue basic dyes and is put on the market frequently in the form of its zinc chloride double salt, which is soluble in water. Acid oxidants in dilute aqueous solution convert it into methylene azure.

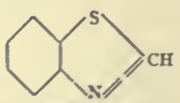
See further A. Bernthsen, *Ann.*, 230, p. 73; 251, p. 1; German Patents 45839 (1887); 47374 (1888). For a discussion as to the constitution of these dyestuffs, whether they are quaternary ammonium salts or thionium salts, see A. Hantzsch, *Ber.*, 1906, 39, pp. 153, 1365; F. Kehrmann, *ibid.*, 1906, 39, p. 914.

THIAZOLES, in organic chemistry, a series of heterocyclic compounds containing the grouping shown below; the replaceable hydrogen atoms in which are designated α, β and μ. They are prepared by condensing thio-amides with α-haloid ketones or aldehydes, the thio-amide reacting as the tautomeric thio-imino acid. Amino derivatives similarly result from thio-ureas and α-haloid ketones; the oxy derivatives from α-sulphocyanoketones by the action of caustic alkali; and the carboxylic acids from chloro-aceto-acetic ester, &c. and thioamides. The thiazoles are somewhat basic in character, and combine with the alkyl iodides to form thiazolium iodides.

Dihydrothiazoles, or thiazolines, are obtained by condensing ethylene dibromides with thio-amides; by the action of β-haloid alkylamines on thio-amides (S. Gabriel, *Ber.*, 1891, 24, p. 783; 1896, 29, p. 2610); and by the action of phosphorus pentasulphide on acyl-β-bromalkylamides (A. Salomon, *Ber.*, 1893, 26, p. 1328). They are much less stable than the thiazoles. The benzothiazoles are a series of weak bases formed by condensing carboxylic acids with ortho-aminothiophenols (A. W. Hofmann, *Ber.*, 1880, 13, p. 1224), by heating the acid anilides with sulphur or by the oxidation of thio-anilides. On fusion with caustic alkalis they decompose into their constituent aminothiophenol and acid. Derivatives of this group are important as substantive cotton dyestuffs.



Thiazole.



Benzothiazole.

THIBAUDEAU, CLAIR ANTOINE, Comte (1765–1854), French politician, was born on the 23rd of March 1765, the son of Antoine de Thibaudeau (1739–1813), a lawyer of Poitiers and a deputy to the States-General of 1789. He was admitted to the bar in 1787, and in 1789 accompanied his father to the States-General at Versailles. When he returned to Poitiers in October he immediately set up a local revolutionary club, and in 1792 was returned as a deputy to the Convention.

Thibaudeau joined the party of the Mountain and voted for the death of Louis XVI. unconditionally. Nevertheless he incurred a certain amount of suspicion because he declined to join the Jacobin Club. In May 1793 he was on a special mission in the west and prevented his department from joining the Federalist movement. Thibaudeau occupied himself more particularly with educational business, notably in the organization of the museum of the Louvre. It was he who secured the inclusion of Tom Paine's name in the amnesty of Girondist deputies. Secretary and then president of the Convention for a short period, he served on the Committee of Public Safety and of Generaly Security. After the insurrection of 13 Vendémiaire (5th October 1795) he opposed those Thermidorians who wished to postpone the dissolution of the Convention. At the elections for the Corps Législatif he was elected by no less than thirty-two departments. It was only by the intervention of Boulay de la Meurthe that he escaped transportation after the *coup d'état* of 18 Fructidor (4th September 1797), and he then returned to the practice of his profession. The establishment of the consulate brought him back to public life. He was made prefect of the Gironde, and then member of the council of state, in which capacity he worked on the civil code. He at this time had Napoleon's confidence, and gave him wholehearted support. He did not entirely conceal his disapproval of the foundation of the Legion of Honour, of the Concordat and of the Consulate for life, and his appointment as prefect of the Bouches du Rhône, with consequent banishment from Paris, was a semi-disgrace.

A peer of the Hundred Days, he fled at the second Restoration to Lausanne. During his exile he lived in Vienna, Prague, Augsburg and Brussels, occupying himself with his *Mémoires sur la Convention et le Directoire* (Paris, 2 vols., 1824); *Mémoires sur le Consulat: par un ancien conseiller d'état* (Paris, 1827); *Histoire générale de Napoléon Bonaparte* (6 vols., Paris and Stuttgart, 1827–28, vol. iii. not printed); *Le Consulat et l'Empire* vol. i. of which is identical with vol. vi. of the *Histoire de Napoléon* (10 vols.; 1834). The revolution of 1830 permitted his return to France, and he lived to become a member of the Imperial Senate under the third empire. He died in Paris on the 8th of March 1854 in his eighty-ninth year.

The special value of Thibaudeau's works arises from the fact that he wrote only of those events of which he had personal knowledge, and that he quotes with great accuracy Napoleon's actual words. His *Mémoires sur le Consulat* has been translated into English, with introduction and necessary notes, by G. K. Fortescue with the title of *Bonaparte and the Consulate* (1908). Among the papers left by Thibaudeau were documents entitled *Ma Biographie* and *Mémoires avant ma nomination à la Convention.* These were published in a small volume (Paris and Niort, 1875) which includes a list of his works and of the narrative of his life.

THIBAUT (or Theobald) **IV.** (1201–1253), count of Champagne and Brie, and king of Navarre, French poet, was born at Troyes in 1201. His father, Thibaut III. of Champagne, died before his son's birth, and his mother, Blanche of Navarre, was compelled to resign the guardianship of the young prince to Philip Augustus, king of France, but there is little doubt that the child was acquainted with Chrétien de Troyes and the other trouvères who found patronage at the court of Champagne. Thibaut's verses belong to what is called "courteous" poetry, but they have a personal note that distinguishes them from mere exercises. They are addressed to Blanche of Castille, the wife of Louis VIII., and Thibaut's relations with her have been the subject of much controversy. The count took part with Louis in the crusade against the Albigenses, but in 1226, with no apparent reason, left the king and returned to Champagne. Three months later Louis died under doubtful circumstances, and Thibaut was accused by his enemies of poisoning him to facilitate his own intrigue with Blanche. The real reason for Thibaut's desertion appears to have been a desire to consolidate his position as heir-apparent of Navarre by an alliance with the disaffected nobility of the south of France, but from this confederation Blanche was skilful enough to detach him. The resentment of the league involved him in a war in which Champagne was laid waste, and his capital saved only by the royal intervention. In 1234 he succeeded his uncle, Sancho VII., as king of Navarre, and from this period date his most fervent songs in praise of his lady. The crusade turned Thibaut's thoughts to religion, and he announced his intention of singing henceforth only in honour of the Virgin. Unfortunately his devotion took darker forms, for before sailing for the Holy Land he ordered and witnessed the burning of a hundred and eighty-three unfortunate men and women convicted of Manichaeism. The years 1239 and 1240 were spent in Palestine, and from the time of his return Thibaut devoted himself to efforts for the improvement of his dominions that won for him the title of *le Bon*. He died at Pampeluna on the 14th of July 1253.

Thibaut was the most popular of all the 13th century song-writers, and his work is marked by a grace and sweetness which he owes perhaps in part to his association with the troubadours of the south. He is said to have set his own songs to music. It seems doubtful whether the notes that have come down to us can with justice be attributed to him, but there is no contesting the musical quality of his verse. His fame spread beyond the Alps, and Dante admired his poetry. He was one of the most celebrated authors of *jeux-partis*, elaborate discussions between two interlocutors, usually on the subject of love.

His works were edited in 1851 by P. Tarbé in his *Chansonniers de Champagne*.

THIBAUT, ANTON FRIEDRICH JUSTUS (1774–1840), German jurist, was born at Hameln, in Hanover, on the 4th of January 1774, the son of an officer in the Hanoverian army, of French Huguenot descent. After passing his school-days in Hameln and Hanover, young Thibaut entered the university of Göttingen as a student of jurisprudence, went thence to Königsberg, where he studied under Kant, and afterwards to Kiel, where he was a fellow-student with Niebuhr. Here, after taking his degree of *doctor juris*, he became a *Privatdozent*. In 1798 he was appointed extraordinary professor of civil law, and in the same year appeared his *Versuche über einzelne Theile der Theorie des Rechts* (1798), a collection of essays on the theory of law, of which by far the most important was entitled *Über den Einfluss der Philosophie auf die Auslegung der positiven Gesetze*, wherein he sought to show that history without philosophy could not interpret and explain law. In 1799 was published his *Theorie der logischen Auslegung des römischen Rechts*, one of his most remarkable works. In 1802 he published a short criticism of Feuerbach's theory of criminal law, which recalls in many ways the speculations of Bentham. The same year appeared *Über Besitz und Verjährung*, a treatise on the law of possession and the limitation of actions. In 1802 Thibaut was called to Jena, where he spent three years and wrote, in Schiller's summer-house, his chief work, *System des Pandektenrechts* (1803), which ran into many editions. The fame of this book depends before all else upon the fact that it was the first modern complete compendium of the subject, distinguished alike by the accuracy of its sources and the freedom and unpedantic manner in which the subject is handled. It is, in effect, a codification of the Roman law as it then obtained in Germany, modified by Canon law and the practice of the courts into a comprehensive system of Pandect law. At the invitation of the grand-duke of Baden he went to Heidelberg to fill the chair of civil law and to assist in organizing the university; and he never quitted that town, though he received in after years, as his fame grew, invitations to Göttingen, Munich and Leipzig. His class was large, his influence great; and, except Gustav Hugo and Savigny, no civilian of his time was so well known. In 1814 appeared his *Civilistische Abhandlungen*, of which the principal was his famous essay, the parent of so much literature, on the necessity of a national code for Germany (*vide infra*). In 1819 he was appointed to the upper house of the newly constituted Baden parliament. He was also made member of the Scheidungsgericht (divorce court). In 1836 Thibaut published his *Erörlerungen des römischen Rechts*. One of his last works was a contribution in 1838 to the *Archiv für die civilistische Praxis*, of which he was one of the editors (see below). Thibaut married, in 1800, a daughter of Professor Ahlers of Kiel. He died after a short illness, at Heidelberg, on the 29th of March 1840.

Thibaut, a man of strong personality and manly consistent nature, was much more than a jurist: he deserves to be remembered in the history of music. Palestrina and the early composers of church music were his delight; and in 1824 appeared anonymously his work, *Über die Reinheit der Tonkunst*, in which he eulogized the old music, and especially that of Palestrina. He was an ardent collector of old compositions, and often sent young men to Italy, at his own expense, to discover interesting musical manuscripts. Among the masters of German prose, too, Thibaut holds no mean place. His style is simple and manly, but rich in the happy accidents of expression which come only to true artists.

Most of Thibaut's works have already been mentioned, but his essay on the necessity of a code for Germany (*Über die Nothwendigkeit eines allegemeinen bürgerlichen Rechts für Deutschland*), which was inspired by the enthusiasm of the war of Liberation and written in fourteen days, deserves further notice. Thibaut himself explained in the *Archiv für die civilistische Praxis*, in 1838, the origin of this memorable essay. He had realized the change denoted by the march of German soldiers to Paris in 1814, and the happy future opened up for Germany. The system of small states he hoped and believed would continue; for the big state he considered crushing to the life of the individual and harmful as concentrating the "warm life" of the nation in one central point. In his judgment the only unity practicable and needful for Germany was that of law; and for this he urged all the German governments to labour. The essay was as much a condemnation of the entire state of jurisprudence as an argument for codification; it was a challenge to civilians to justify their very existence. Savigny took up the challenge thus thrown down; and a long controversy as to points not very clearly defined took place. The glory of the controversy belonged to Savigny; the real victory rested with Thibaut.

The framers of the new German civil code (*bürgerliches Gesetzbuch*) in 1879 were indebted for the arrangement of their matter in no small degree to Thibaut's method and clear classification, but beyond this, the code, based on the common law of the several German states, which was adroitly blended by the *usus pandectarum* into an harmonious whole, does not reflect his influence. He was one of the earliest to criticize the divisions found in the Institutes, and he carried on with Gustav Hugo a controversy as to these points.

In modern German legal literature Thibaut's influence is not very perceptible. Even at Heidelberg it was quickly superseded by that of his successor, Karl Adolf von Vangerow (1805–1870), and in Germany his works are now little used as text-books. But those best able to judge Thibaut have most praised him. Austin, who owed much to him, describes him as one "who for penetrating acuteness, rectitude of judgment and depth of learning and eloquence of exposition, may be placed by the side of von Savigny, at the head of all living civilians."

For further information as to Thibaut's life and work, see Baumstark, *Thibaut, Blätter der Erinnerung* (1841); Karl Hagemann, *Aus dem Leben H. F. J. Thibaut, mit Correspondenz*, in *die Preuss. Jahrbücher* (1880); Teichmann, in *Holtzendorff's Rechtslexikon;* and E. Landsberg, in *Allgemeine Deutsche Biographie*, vol. 37.

THIBAW, or HSIPAW, one of the Northern Shan States of Burma. It is called by the Shans, and officially, Hsipaw, and also frequently Ông Pawng (the name of an old capital). It includes four states—Thibaw, the main state, and the sub-states of Möng Lông, Möng Tung and Thonzè (or Hsumhsai). The whole state has an area of 5086 sq. m., and the population in 1901 was 104,700. The main state lies on the geological fault which runs east and west across the Shan States, from the Salween at Kunlông and beyond to nearly the rim of the Shan tableland at Gôkteik. It is therefore broken up into a mass of not very well-defined ridges and spurs, crossing and re-entering. The chief plain land is in the valley of the Nam Tu (Myit-ngè), near Thibaw town, and the valley or strath of the Pyawng Kawng, Nawng Ping neighbourhood. Elsewhere the valleys are insignificant. The hills on the Möng Tung border reach their highest elevations in the peaks Loi Pan (6848 ft.) and Loi Htan (6270 ft.). To the north-west of Thibaw town, on the Tawng Peng border, Loi Lam rises to 6486 ft. The valley of the Nam Tu marks the lowest point in the state at Thibaw town, about 1400 ft., and rises on the east in Möng Tung to a plain level of about 2500 ft., and on the west in Möng Lông to a confused mass of hills with an average height of 4500 ft., broken up by the Nam Yawn and Nam Kaw valleys, which are about 3000 ft. above mean sea-level.

The chief river is the Nam Tu or Myit-ngè, also frequently called by its classical name the Dôktawadi. The main stream rises in the Salween-Irrawaddy watershed, and is enlarged by considerable tributaries. At Thibaw town it is 250 yds. wide and about 8 ft. deep, with a fairly strong current. The Nam Tu is navigable only in local stretches, and between Thonzè and Lawksawk (Yatsauk) it flows through a gorge between cliffs 3000 to 4000 ft. high. At the gorge of Hokût (Ngôkteik) the Nam Htang and the Nam Pasè unite to form the Nam Küt, which passes into the ground at the natural bridge where the Mandalay-Kunlông railway crosses the gorge, and reappears to join the Nam Tu. The bed of the Nam Küt is about 1500 ft. below the general level of the country. Coal is found at various places in the state, but is not of very high quality. Salt-wells are worked by the inhabitants of Mawhkio (Bawgyo) about 7 m. from Thibaw town. The average maximum temperature at the beginning of April is about 96°, and the minimum about the same period 65°. The rainfall averages about 70 in. for the year. The chief crops are rice, cotton, sesamum, tea in the hills, and *thanat*, the leaf of a tree used for the wrapper of the Burma, or "green" cheroot. Cotton cloth was formerly much more generally manufactured than it now is, and a coarse country paper is also made. Other industries are merely of articles for local use. The government cart road to Lashio passes through the centre of the state, and from this various unmetalled roads radiate to different parts of the state and the neighbouring states. The Mandalay-Kunlông railway, now open as far as Lashio, also passes through the capital. Teak forests exist along the banks of the Nam Tu and in the Möng Lông states, but both have been practically exhausted, and will have to be closed for many years. Previous to the annexation, and in a general way still, the state is administered by the *sawbwa*, or chief, aided by a council of six *amats* or ministers. Under them are a number of *nè-baings*, who are in charge of circles and townships. Each *nè-baing* has an *asiyin*, or clerk, and each village has a headman, or *kin-man*. The *amats* supervise the administration of a certain number of districts. The old system is now being assimilated to that followed in Burma. The chief Sao Hkè was for a time in England. (J. G. Sc.)

THIELMANN, JOHANN ADOLF, Freiherr von (1765–1824), Prussian cavalry soldier, was born at Dresden. Entering the Saxon cavalry in 1782, he saw service against the French in the Revolutionary Wars and in the Jena campaign. When, after the disaster of Jena, Saxony allied herself with her conqueror, Thielmann accompanied the Saxon contingent which fought at the siege of Danzig and at Friedland. In 1809, as colonel of a Free-Corps, he opposed the advance of the Austrians into Saxony, and was rewarded for his services with the grade of major-general, further promotion to lieutenant-general following in 1810. As commander of the Saxon Heavy Cavalry Brigade he took part in the advance on Moscow two years later, and his conduct at Borodino attracted the attention of Napoleon, who took Thielmann into his own suite. His own sovereign at the same time made him Freiherr. In the war of Liberation Thielmann took a prominent part; as governor of Torgau, by his king's orders he at first observed the strictest neutrality, but on receipt of an order to hand over the fortress to the French he resigned his command and, accompanied by his staff officer Aster, joined the allies. As a Russian general he was employed in reorganizing the Saxon army after Leipzig, and in 1814 he commanded the Saxon corps operating in the Low Countries. Early in the following year he became a lieutenant-general in the Prussian service, and in command of the 3rd army corps he took part in the Waterloo campaign. From the field of Ligny he retired with the rest of Blücher's army on Wavre, and when the other corps marched towards Waterloo, Thielmann covered this movement against Grouchy, fighting the spirited action of Wavre (June 18–19). He was later a corps commander at Münster and at Coblenz, and at the latter place he died in 1824.

See von Hütel, *Biographische Skizze des Generals von Thielmann* (Berlin, 1828); von Holzendorff, *Beiträge zur Biographie des Generals Freiherrn von Thielmann* (Dresden, 1830); von Petersdorf, *General Johann Adolf Freiherr von Thielmann* (Leipzig, 1894).

THIERRY, the name of two French historians, the brothers Augustin and Amédée, both of whom, though their literary and historical powers were far from being equal, displayed the same devotion to historical study.

I. Jacques Nicolas Augustin Thierry (1795–1856), the elder and more gifted, was born at Blois on the 10th of May 1795. He had no advantages of birth or fortune, but was greatly distinguished at the Blois Grammar School, and entered the *École normale supérieure* (1811). In 1813 he left it, and was sent as a professor to Compiègne, but stayed there a very short time. His ardent and generous nature led him to embrace the ideas of the French Revolution with enthusiasm, and he became fired with Saint Simon's ideal society of the future. He became the secretary, and, as he would say himself, the "adopted son" of the famous visionary (1814–17); but, while most of Saint Simon's followers turned their attention to the affairs of life, devoting themselves to the problems, both theoretical and practical, of political economy, Thierry turned his to history. His imagination had been powerfully impressed by reading *Les Martyrs*, in which Châteaubriand had contrasted the two civilizations and the two races from which the modern world has sprung. His romantic ardour was later still further nourished by the works of Sir Walter Scott, and though he did not himself actually write romances, his conception of history fully recognized the dramatic element. His main ideas on the Germanic invasions, the Norman Conquest, the formation of the Communes, the gradual ascent of the nations towards free government and parliamentary institutions are already observable in the articles contributed by him to the *Censeur européen* (1817–20), and later in his *Lettres sur l'histoire de France* (1820). From Fauriel he learnt to use the original authorities; and by the aid of the Latin chronicles and the collection, as yet very ill understood, of the Anglo-Saxon laws, he composed his *Histoire de la Conquête de l'Angleterre par les Normands*, the appearance of which was greeted with great enthusiasm (1825). It was written in a style at once precise and picturesque, and was dominated by an idea, at once generous and false, that of Anglo-Saxon liberty resisting the invasions of northern barbarians, and reviving, in spite of defeat, in the parliamentary monarchy. His artistic talent as a writer makes the weaknesses and deficiencies of his scholarship less obvious. This work, the preparation of which had required several years of hard work,. cost Thierry his eyesight; in 1826 he was obliged to engage secretaries and in 1830 became quite blind. Notwithstanding, he continued to produce works. In 1827 he republished his *Lettres sur l'histoire de France*, with the addition of fifteen new ones, in which he described some of the more striking episodes in the history of the rise of the medieval communes. The chronicles of the 11th and 12th centuries and a few communal charters provided him, without requiring a great amount of erudition, with materials for a solid work. For this reason his work on the communes has not become so out of date as his Norman Conquest; but he was too apt to generalize from the facts furnished by a few striking cases which occurred in a small portion of France, and helped to spread among the public, and even among professional historians, mistaken ideas concerning one of the most complex problems relating to the social origins of France.

Thierry was ardent in his applause of the July Revolution and the triumph of liberal ideas; at this time, too, his brother Amédée was appointed prefect, and he went to live with him for four years. He now re-edited, under the title of *Dix ans d'études historiques*, his first essays in the *Censeur européen* and the *Courrier français* (1834), and composed his *Récits des temps mérovingiens*, in which he reproduced in a vivid and dramatic form some of the most characteristic stories of Gregory of Tours. These *Récits* appeared first in the *Revue des deux mondes*; when collected in volume form, they were preceded by long and interesting *Considérations sur l'histoire de France.* From the 7th of May 1830, Thierry had already been a member of the *Académie des Inscriptions et Belles Lettres;* in 1841, on the motion of Villemain, the French Academy awarded him the first *Prix Gobert*, which became a kind of literary inheritance for him, being renewed in his favour fifteen years in succession. Moreover, he had been allotted the task of publishing in the series of the *Documents inédits* a selection of acts bearing on the history of the Third Estate. By the aid of zealous collaborators (including Bourquelot and Louandre) he compiled, in four volumes, a valuable *Recueil des monuments inédits de l'histoire du Tiers État* (1850–70), which, however, bear only on the northern part of France. The preface appeared afterwards in a separate volume under the title of *Histoire du Tiers État.* To Thierry belongs the credit for inaugurating in France the really critical study of the communal institutions, and we cannot make him responsible for the neglect into which it relapsed after his death. The last years of his life were clouded by domestic griefs and by illness. In 1844 he lost his wife, Julie de Quérengal, an intelligent woman, who had been to him a collaborator as capable as she was devoted. The revolution of 1848 inflicted on him a final blow.

by overturning that régime of the Liberal *bourgeoisie* the triumph of which he had hailed and justified as the necessary outcome of the whole course of French history. He began to distrust the rationalistic opinions which had hitherto estranged him from the Church. When Catholic writers animadverted on the "historical errors" in his writings he promised to correct them, and accordingly we find that in the final edition of his *Histoire de la Conquête* his severe judgments on the policy of the court of Rome, together with some faults of detail, are eliminated. Though he did not renounce his Liberal friends, he sought the conversation of enlightened priests, and just before his death he seems to have been disposed to enter the pale of the Church. He died in Paris on the 22nd of May 1856, after several years of suffering endured with heroism.

II. Amédée Simon Dominique Thierry (1797–1873) was the younger brother of Augustin, and was born on the 2nd August 1797. He began life as a journalist (after an essay, like his brother, at schoolmastering), was connected with the famous romantic harbinger the *Globe*, and obtained a small government clerkship. His first book was a brief history of Guienne in 1825, and three years later appeared the first volume of the *Histoire des Gaulois*, which was received with much favour, and obtained him, from the royalist premier Martignac, a history professorship at Besançon. He was, however, thought too liberal for the government of Charles X., and his lectures were stopped, with the result of securing him, after the revolution, the important post of prefect of the Haute-Saône, which he held eight years. During this time he published nothing. In 1838 he was transferred to the council of state as master of requests, which post he held through the revolution of 1848 and the *coup d' état* till 1860, when he was made senator—a paid office, it must be remembered, and, in effect, a lucrative sinecure. He also passed through all the ranks of the Legion of Honour, became a member of the Académie des Inscriptions in 1841, and in 1862 received the honorary degree of D.C.L. at Oxford. He had, except during the time of his prefecture, never intermitted his literary work, being a constant contributor to the *Revue des deux mondes*, his articles (usually worked up afterwards into books) almost all dealing with Roman Gaul and its period. The chief were the *Histoire des Gaulois*, 3 vols. (1828, 1834, 1845; the 8th edition of vol. i. appeared in 1870); *Histoire de la Gaule sous l'administration romaine* (3 vols., 1840–47; 2nd ed. 1871); *Histoire d'Attila, de ses fils et successeurs jusqu'à l'établissement des Hongrois en Europe* (1856; 5th ed. in 1874); *Tableau de l'Empire romain* (1862; 5th ed. in 1871; now quite out of date); *Récits de l'histoire romaine au Ve siècle: la lutte contre les Barbares*, and *les luttes religieuses* (1860; 2nd ed. in 6 vols. 1880). He died in Paris on the 27th of March 1873. His son, Gilbert Augustin Thierry (born 1843), who began a literary career by articles on *Les Révolutions d'Angleterre* (1864) and some *Essais d'histoire religieuse* (1867), afterwards confined himself to the writing of novels. (C. B.*)

THIERS, LOUIS ADOLPHE (1797–1877), French statesman and historian, was born at Marseilles on the 16th of April 1797. His family are somewhat grandiloquently spoken of as "cloth merchants ruined by the Revolution," but it seems that at the actual time of his birth his father was a locksmith. His mother belonged to the family of the Chéniers, and he was well educated, first at the lycée of Marseilles, and then in the faculty of law at Aix. Here he began his lifelong friendship with Mignet, and was called to the bar at the age of twenty-three. He had, however, little taste for law and much for literature; and he obtained an academic prize at Aix for a discourse on Vauvenargues. In the early autumn of 1821 Thiers went to Paris, and was quickly introduced as a contributor to the *Constitutionnel*. In each of the years immediately following his arrival in Paris he collected and published a volume of his articles, the first on the salon of 1822, the second on a tour in the Pyrenees. He was put out of all need of money by the singular benefaction of Cotta, the well-known Stuttgart publisher, who was part-proprietor of the *Constitutionnel*, and made over to Thiers his dividends, or part of them. Meanwhile he became very well known in Liberal society, and he had begun the celebrated *Histoire de la révolution française*, which founded his literary and helped his political fame. The first two volumes appeared in 1823, the last two (of ten) in 1827. The book brought him little profit at first, but became immensely popular. The well-known sentence of Carlyle, that it is "as far as possible from meriting its high reputation," is in strictness justified, for all Thiers's historical work is marked by extreme inaccuracy, by prejudice which passes the limits of accidental unfairness, and by an almost complete indifference to the merits as compared with the successes of his heroes. But Carlyle himself admits that Thiers is "a brisk man in his way, and will tell you much if you know nothing." Coming as the book did just when the reaction against the revolution was about to turn into another reaction in its favour, it was assured of success.

For a moment it seemed as if the author had definitely chosen the lot of a literary man, not to say of a literary hack. He even planned an *Histoire générale*. But the accession to power of the Polignac ministry in August 1829 changed his projects, and at the beginning of the next year Thiers, with Armand Carrel, Mignet, and others started the *National*, a new opposition newspaper. Thiers himself was one of the souls of the actual revolution, being credited with "overcoming the scruples of Louis Philippe," perhaps no Herculean task. At any rate he had his reward. He ranked as one of the Radical supporters of the new dynasty, in opposition to the party of which his rival Guizot was the chief literary man, and Guizot's patron, the duc de Broglie, the main pillar. At first Thiers, though elected deputy for Aix, obtained only subordinate places in the ministry of finance. After the overthrow of his patron Laffitte, he became much less radical, and, after the troubles of June 1832, was appointed to the ministry of the interior. He repeatedly changed his portfolio, but remained in office for four years, became president of the council and in effect prime minister, and began his series of quarrels and jealousies with Guizot. At the time of his resignation in 1836 he was foreign minister, and, as usual, wished for a spirited policy in Spain, which he could not carry out. He travelled in Italy for some time, and it was not till 1838 that he began a regular campaign of parliamentary opposition, which in March 1840 made him president of the council and foreign minister for the second time. But he held the position barely six months, and, being unable to force on the king an anti-English and anti-Turkish policy, resigned on the 29th of October. He now had little to do with politics for some years, and spent his time on his *Histoire du Consulat et de l'Empire*, the first volume of which appeared in 1845. Though he was still a member of the chamber he spoke rarely, till after the beginning of 1846, when he was evidently bidding once more for power. Immediately before the revolution of February he went to all but the greatest lengths, and when it broke out he and Odillon Barrot were summoned by the king; but it was too late. Thiers was unable to govern the forces he had helped to gather, and he resigned.

Under the republic he took up the position of conservative republican, which he ever afterwards maintained, and he never took office. But the consistency of his conduct, especially in voting for Prince Louis Napoleon as president, was often and sharply criticized, one of the criticisms leading to a duel with a fellow-deputy, Bixio. He was arrested at the *coup d'état*, was sent to Mazas, and then escorted out of France. But in the following summer he was allowed to return. For the next decade his history was almost a blank, his time being occupied for the most part on *The Consulate and the Empire*. It was not till 1863 that he re-entered political life, being elected by a Parisian constituency. For the seven years following he was the chief speaker among the small band of anti-Imperialists in the French chamber, and was regarded generally as the most formidable enemy of the empire. While nominally protesting against its foreign enterprises, he perpetually harped on French loss of prestige, and so contributed more than any one else to stir up the fatal spirit which brought on the war of 1870. Even when the Liberal-Imperialist Ollivier ministry was formed, he maintained at first an anything but benevolent neutrality, and then an open opposition, and it is impossible to be sure whether mere "canniness," or something better, kept him from joining the government of the National Defence, of which he was in a manner the author.

Nevertheless the collapse of the empire was a great opportunity for Thiers, and it was worthily accepted. He undertook in the latter part of September and the first three weeks of October a circular tour to the different courts of Europe in the hope of obtaining some intervention, or at least some good offices. The mission was unsuccessful; but the negotiator was on its conclusion immediately charged with another—that of obtaining, if possible, an armistice directly from Prince Bismarck. The armistice having been arranged, and the opportunity having been thus obtained of electing a National Assembly, Thiers was chosen deputy by more than twenty constituencies (of which he preferred Paris), and was at once elected by the Assembly itself practically president, nominally *chef du pouvoir exécutif*. He lost no time in choosing a coalition cabinet, and then personally took up the negotiation of peace. Probably no statesman has ever had a more disgusting task; and the fact that he discharged it to the satisfaction of a vast majority is the strongest testimony to Thiers's merits. He succeeded in convincing the deputies that the peace was necessary, and it was (March 1, 1871) voted by more than five to one.

Thiers held office for more than two years after this event, which shows the strength of the general conviction that he alone could be trusted. He had at first to meet and crush at once the mad enterprise of the Paris commune. Soon after this was accomplished he became (August 30th) in name as well as in fact president of the republic.

His strong personal will and inflexible opinions had much to do with the resurrection of France; but the very same facts made it inevitable that he should excite violent opposition. He was a confirmed protectionist, and free trade ideas had made great way in France under the empire; he was an advocate of long military service, and the devotees of *la revanche* were all for the introduction of general and compulsory but short service. Both his talents and his temper made him utterly indisposed to maintain the attitude supposed to be incumbent on a republican president; and his tongue was never a carefully governed one. In January 1872 he formally tendered his resignation; and though it was refused, almost all parties disliked him, while his chief supporters—men like Rémusat, Barthélemy Saint-Hilaire and Jules Simon—were men rather of the past than of the present.

The year 1873 was, as a parliamentary year in France, occupied to a great extent with attacks on Thiers. In the early spring regulations were proposed, and on April 13th were carried, which were intended to restrict the executive and especially the parliamentary powers of the president. On the 27th of the same month a contested election in Paris, resulting in the return of the opposition candidate, M. Barodet, was regarded as a grave disaster for the Thiers government, and that government was not much strengthened by a dissolution and reconstitution of the cabinet on May 19th. Immediately afterwards the question was brought to a head by an interpellation moved by the duc de Broglie. The president declared that he should take this as a vote of want of confidence; and in the debates which followed a vote of this character (though on a different formal issue, and proposed by M. Ernoul) was carried by 16 votes in a house of 704. Thiers at once resigned (May 24th).

He survived his fall four years, continuing to sit in the Assembly, and, after the dissolution of 1876, in the Chamber of Deputies, and sometimes, though rarely, speaking. He was also, on the occasion of this dissolution, elected senator for Belfort, which his exertions had saved for France; but he preferred the lower house, where he sat as of old for Paris. On May 16th 1877, he was one of the "363" who voted want of confidence in the Broglie ministry (thus paying his debts), and he took considerable part in organizing the subsequent electoral campaign. But he was not destined to see its success, being fatally struck with apoplexy at St Germain-en-Laye on September 3rd. Thiers had long been married, and his wife and sister-in-law, Mlle Dosne, were his constant companions; but he left no children, and had had only one—a daughter—who long predeceased him. He had been a member of the Academy since 1834. His personal appearance was remarkable, and not imposing, for he was very short, with plain features, ungainly gestures and manners, very near-sighted, and of disagreeable voice; yet he became (after wisely giving up an attempt at the ornate style of oratory) a very effective speaker in a kind of conversational manner, and in the epigram of debate he had no superior among the statesmen of his time except Lord Beaconsfield.

Thiers was by far the most gifted and interesting of the group of literary statesmen which formed a unique feature in the French political history of the 19th century. There are only two who are at all comparable to him—Guizot and Lamartine; and as a statesman he stands far above both. Nor is this eminence merely due to his great opportunity in 1870; for Guizot might under Louis Philippe have almost made himself a French Walpole, at least a French Palmerston, and Lamartine's opportunities after 1848 were, for a man of political genius, illimitable. But both failed—Lamartine almost ludicrously—while Thiers in hard conditions made a striking if not a brilliant success. But he only showed well when he was practically supreme. Even as the minister of a constitutional monarch his intolerance of interference or joint authority, his temper at once imperious and intriguing, his inveterate inclination towards *brigue*, that is to say, underhand rivalry and caballing for power and place, showed themselves unfavourably; and his constant tendency to inflame the aggressive and chauvinist spirit of his country neglected fact, was not based on any just estimate of the relative power and interests of France, and led his country more than once to the verge of a great calamity. In opposition, both under Louis Philippe and under the empire, and even to some extent in the last four years of his life, his worst qualities were always manifested. But with all these drawbacks he conquered and will retain a place in what is perhaps the highest, as it is certainly the smallest, class of statesmen—the class of those to whom their country has had recourse in a great disaster, who have shown in bringing her through that disaster the utmost constancy, courage, devotion and skill, and who have been rewarded by as much success as the occasion permitted.

As a man of letters Thiers is very much smaller. He has not only the fault of diffuseness, which is common to so many of the best-known historians of his century, but others as serious or more so. The charge of dishonesty is one never to be lightly made against men of such distinction as his, especially when their evident confidence in their own infallibility, their faculty of ingenious casuistry, and the strength of will which makes them (unconsciously, no doubt) close and keep closed the eyes of their mind to all inconvenient facts and inferences, supply a more charitable explanation. But it is certain that from Thiers's dealings with the men of the first revolution to his dealings with the battle of Waterloo, constant, angry and well-supported protests against his unfairness were not lacking. Although his search among documents was undoubtedly wide, its results are by no means always accurate, and his admirers themselves admit great inequalities of style in him. These characteristics reappear (accompanied, however, by frequent touches of the epigrammatic power above mentioned, which seems to have come to Thiers more readily as an orator or a journalist than as an historian) in his speeches, which after his death were collected in many volumes by his widow. Sainte-Beuve, whose notices of Thiers are generally kindly, says of him, "M. Thiers sait tout, tranche tout, parle de tout," and this omniscience and "cocksureness" (to use the word of a prime minister of England contemporary with this prime minister of France) are perhaps the chief pervading features both of the statesman and the man of letters.

His histories, in many different editions, and his speeches, as above, are easily accessible; his minor works and newspaper articles have not, we believe, been collected in any form. Several years after his death appeared *Deux opuscules* (1891) and *Mélanges inédites* (1892), while *Notes et souvenirs*, 1870–73, were published in 1901 by "F. D.," his sister-in-law and constant companion, Mlle Félicie Dosne. Works on him, by M. Laya, M. de Mazade, his colleague and friend M. Jules Simon, and others, are numerous.

(G. Sa.)

THIERS, a town of central France, capital of an arrondissement in the department of Puy-de-Dôme, 24 m. E.N.E. of Clermont-Ferrand, on the railway between that town and St Étienne. Pop. (1906) town, 12,601; commune, 17,418. Thiers is most picturesquely situated on the side of a hill at the foot of which the Durolle rapidly descends through a narrow valley into the Dore, a tributary of the Allier. The streets rising in steep rows contain a large number of stone and wooden houses, some of which date to the 15th century. A fine view of the Plain of Limagne and the Dôme mountain is obtainable from the terraces. The church of St Genès was built in 575 by Avitus, bishop of Clermont, and rebuilt in the 12th century. It has some curious mosaic work of the Merovingian period and a fine tomb of the 13th century. The church of Le Moutier, which formerly formed part of a Benedictine monastery, dates chiefly from the 11th century. Thiers is the seat of a sub-prefect and has tribunals of first instance and of commerce, a chamber of commerce, a board of trade arbitration, a communal college, a commercial and industrial school, and a branch of the Bank of France. Its special industry is the manufacture of cutlery, which employs some 12,000 hands in the town and its vicinity. The manufacture of handles and buttons of bone, pasteboard, stamping, hand-made and other papers and machinery are also carried on.

Thiers was sacked about 531 by the soldiers of Thierry, son of Clovis. About the same period Gregory of Tours speaks of a wooden chapel which may have occupied the site of the present church of Le Moutier. The commercial importance of the town was much increased in the 16th century when the manufacture of cutlery was introduced from the neighbouring town of Chateldon.

THIERSCH, FRIEDRICH WILHELM (1784–1860), German classical scholar and educationist, was born at Kirchscheidungen near Freiburg on the Unstrut, on the 17th of June 1784. In 1809 he became professor at the gymnasium at Munich, and in 1826 professor of ancient literature in the university of Landshut, transferred in that year to Munich. He died at Munich on the 25th of February 1860. Thiersch, the "tutor of Bavaria" (*praeceptor Bavariae*), found an extremely unsatisfactory system of education in existence. There was a violent feud between the Protestant "north" and the Catholic "south" Germans; Thiersch's colleagues, chiefly old monks, offered violent opposition to his reforms, and an attempt was made upon his life. His schemes, however, were carried out, and have remained the governing principle of the educational institutions of Bavaria. Thiersch was an ardent supporter of Greek independence. In 1832 he visited Greece, and it is said that his influence had much to do with securing the throne of the newly created kingdom for Otto of Bavaria. He wrote a Greek grammar, a metrical translation of Pindar, and an account of Greece (*L'État actuel de la Grèce* (1833).

Biography by his son, H. W. J. Thiersch (1866); see also G. M. Thomas, *Gedächtnissrede auf Friedrich von Thiersch* (1860); articles by A. Baumeister in *Allgemeine Deutsche Biographie* and O. Zöckler in Herzog-Hauck's *Realencyclopädie für protestantische Theologie*, xix.; J. E. Sandys, *History of Classical Scholarship*, iii. (1908).

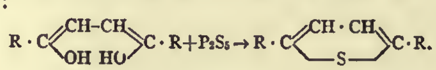
THIETMAR (DIETMAR or DITHMAR) **OF MERSEBURG** (975–1018), German chronicler, was a son of Siegfried, count of Walbeck, and was related to the family of the emperor Otto the Great. Born on the 25th of July 975 he was educated at Quedlinburg and at Magdeburg and became provost of Walbeck in 1002 and bishop of Merseburg seven years later. He took some part in the political events of the time; in 994 he was a hostage in the hands of the Northmen, and he was not unfamiliar with the actualities of war. He died on the 1st of December 1018.

Thietmar wrote a *Chronicon* in eight books, which deals with the period between 908 and 1018. For the earlier part he used Widukind's *Res gestae Saxonicae*, the *Annales Quedlinburgenses* and other sources; the latter part is the result of personal knowledge. It is rough in form and the author shows no power of discriminating between important and unimportant events; yet the chronicle is an excellent authority for the history of Saxony during the reigns of the emperors Otto III. and Henry II. No kind of information is excluded, but the fullest details refer to the bishopric of Merseburg and to the wars against the Wends and the Poles. The original manuscript of the work is preserved at Dresden and has been published in facsimile by L. Schmidt (Dresden, 1905). It has been edited by J. M. Lappenberg in Band III. of the *Monumenta Germaniae historica, Scriptores;* and by F. Kurze (Hanover, 1889); and has been translated into German by J. Laurent (new ed. revised by W. Wattenbach, Leipzig, 1892). See F. Kurze, *Bischof Thietmar von Merseburg und seine Chronik* (Halle, 1890); and W. Wattenbach, *Deutschlands Geschichtsquellen*, Band II. (Berlin, 1904).

THIMBLE, an implement for use in sewing, serving as a protective covering for the finger in pushing the needle through the material worked upon. For ordinary purposes the thimble is a bell-shaped cap reaching to the first joint and is usually worn on the middle finger. It is made of silver or other metal, sometimes of horn, ivory or bone. The sail-maker's thimble or "thummel" is a heavy ring, worn on the thumb, with a disc attached which is the part used to press against the needle. The O.E. *thymel*, from which the word descends, is formed, with the suffix -el, from *thūma*, the thumb, the protective covering having been formerly worn on that digit. The thumb by etymology means the "thick" finger, and is to be referred to the root *tum*, to swell up, become thick, seen in Lat. *tumere*, "tumid," &c. The term "thimble" is used of many mechanical appliances, especially of various forms of sleeve, bushing or joining for the ends of pipes, or shaftings, or as covering for an axle, &c. In nautical usage the "thimble" is a metal ring concave on the outside in which a rope runs; it is a protection against chafing.

THIOPHEN, C_4H_4S, a compound occurring in small quantities in crude coal-tar benzene, from which it was first isolated in 1883 by V. Meyer (*Ber.*, 1883, 16, p. 1465). The method adopted by Meyer to recover the thiophen was as follows. Ten volumes of the purest coal-tar benzene were shaken for four hours with one volume of sulphuric acid, the acid layer was removed and neutralized with lead carbonate, and the lead thiophen sulphonate obtained was distilled with an equivalent quantity of ammonium chloride. The distillate obtained was diluted with one hundred volumes of ligroin (previously purified by shaking with fuming sulphuric acid) and then shaken for one or two hours with sulphuric acid (using ten volumes of acid to one volume of the distillate), the acid layer diluted with water, neutralized by lead carbonate and the lead salt again distilled with an equivalent quantity of ammonium chloride. The distillate is finally rectified. It may be obtained in small quantity by passing ethylene or acetylene into boiling sulphur; by passing ethyl sulphide through a red-hot tube; by heating crotonic acid, butyric acid or erythrite with phosphorus pentasulphide; by heating succinic anhydride with phosphorus pentasulphide or sodium succinate with phosphorus trisulphide (J. Volhard and H. Erdmann, *Ber.*, 1885, 18, p. 454); or by heating succindialdehyde with two parts of phosphorus trisulphide (C. Harries, *Ber.*, 1901, 34, p. 1496).

It is a colourless liquid having a faint smell resembling that of benzene and boiling at 84° C. In its chief properties it very much resembles benzene, being readily brominated, sulphonated, and nitrated; also, the side chains in the alkyl thiophens are readily oxidized to carboxyl groups. On passing its vapour through a red-hot tube it yields di-thiënyl, $C_8H_6S_2$. It is completely decomposed by hydriodic acid at 140° C. It condenses with aldehydes (in chloroform solution) in the presence of phosphorus pentoxide to give dithiënyl hydrocarbons (A. Nahke, *Ber.*, 1897, 30, p. 2037). It can be readily recognized by the blue colour produced when a trace of thiophen is added to isatin dissolved in concentrated sulphuric acid (the *indophenin* reaction). The thiophen ketones may be prepared by the interaction of thiophen and its homologues with acid chlorides in the presence of anhydrous aluminium chloride. The thiophen homologues are best prepared by heating the 1·4 diketones with phosphorus pentasulphide, the diketones reacting in the enolic form:



Thiolenol, or oxymethyl thiophene, is prepared by heating laevulinic acid with phosphorus pentasulphide (W. Kues and C. Paal, *Ber.*, 1886, 19, p. 555). On this group see also V. Meyer, *Die Thiophengruppe.*

THIRLBY (or Thirleby), **THOMAS** (*c.* 1506–1570), English prelate, was born at Cambridge and was educated at Trinity Hall in the university there, becoming a fellow of his college. Through the good offices of his friend, Thomas Cranmer, he was introduced to the court of Henry VIII., and he served this king, one of whose chaplains he had become, in several ways. Among his numerous public appointments were those of dean of the chapel royal and member of the council of the north. In 1540 he was made bishop of Westminster, being the first and only occupant of that see; in 1550, three years after Henry VIII.'s death, he resigned the bishopric, which was dissolved, and became bishop of Norwich. As a diplomatist Thirlby had a long and varied experience; on several occasions he was sent on embassies to the emperor Charles V., and he helped to arrange the peace between England and France in 1559. He appears to have served Edward VI. loyally throughout his short reign, both at home and abroad, although it is certain that he disliked the religious changes and he voted against the act of uniformity in 1549. He was thus more at ease when Mary ascended the throne. Translated in 1554 to the bishopric of Ely, he took part in the trial of Cranmer at Oxford and in the consecration of Reginald Pole as archbishop of Canterbury, but he himself did not take severe measures against heretics. When Elizabeth became queen the bishop refused to take the oath of supremacy; in other ways he showed himself hostile to the proposed religious changes, and in 1559 he was deprived of his bishopric. For preaching against the innovations he was arrested in 1560, and he was in honourable confinement at Lambeth Palace when he died on the 26th of August 1570.

THIRLWALL, CONNOP (1797–1875), English bishop and historian, was born at Stepney, London, on the 11th of January 1797. His family was of Northumbrian extraction. He was a precocious boy, learning Latin at three, reading Greek at four, and writing sermons at seven. He went to the Charterhouse school, where George Grote and Julius Hare were among his schoolfellows. He went up to Trinity College, Cambridge, in October 1814, and gained the Craven university scholarship and the chancellor's classical medal. In October 1818 he was elected to a fellowship, and went for a year's travel on the Continent. At Rome he gained the friendship of Baron (Christian C. J.) von Bunsen, which had a most important influence on his life. On his return, "distrust of his own resolutions and convictions" led him to abandon for the time his intention of being a clergyman, and he settled down to the study of the law, "with a firm determination not to suffer it to engross my time so as to prevent me from pursuing other branches of knowledge." How little his heart was with it was shown by the labour he soon undertook of translating and prefacing Schleiermacher's essay on the Gospel of St Luke. He further rendered two of Tieck's most recent *Novellen* into English. In 1827 he at length made up his mind to quit the law, and was ordained deacon the same year.

Thirlwall now joined with Hare in translating Niebuhr's *History of Rome*; the first volume appeared in 1828. The translation was attacked in the *Quarterly* as favourable to scepticism, and the translators jointly replied. In 1831 the friends established the *Philological Museum*, which lived through only six numbers, though among Thirlwall's contributions was his masterly paper on the irony of Sophocles—"the most exquisite criticism I ever read," says Sterling. On Hare's departure from Cambridge in 1832, Thirlwall became assistant college tutor, which led him to take a memorable share in the great controversy upon the admission of Dissenters which arose in 1834. Thomas Turton, the regius professor of divinity (afterwards dean of Westminster and bishop of Ely), had written a pamphlet objecting to the admission, on the ground of the apprehended unsettlement of the religious opinions of young churchmen. Thirlwall replied by pointing out that no provision for theological instruction was in fact made by the colleges except compulsory attendance at chapel, and that this was mischievous. This attack upon a time-hallowed piece of college discipline brought upon him a demand for the resignation of his office as assistant tutor. He complied at once; his friends generally thought that he ought to have tested the master's power. The occurrence marked him out for promotion by a Liberal Government, and in the autumn he received from Lord Brougham as chancellor the living of Kirby-under-Dale in Yorkshire. Though devoted to his parochial duties, he found time to begin his principal work, the *History of Greece*. This work was a commission from Lardner's *Cabinet Cyclopaedia*, and was originally intended to have been condensed into two or three duodecimo volumes. The scale was enlarged, but Thirlwall always felt cramped. He seems a little below his subject, and a little below himself. As compared with Grote's history it lacks enthusiasm for a definite political ideal and is written entirely from the standpoint of a scholar. It is in this respect superior, and further shows in places a more impartial treatment of the evidence, especially in respect of the aristocratic and absolute governments of Greece. For these reasons its popularity was not so immediate as that of Grote's work, but within recent years its substantial merits have been more adequately recognized. A noble letter from Thirlwall to Grote, and Grote's generous reply, are published in the life of the latter. John Sterling pronounced Thirlwall "a writer as great as Thucydides and Tacitus, and with far more knowledge than they." The first volume was published in 1835, the last in 1847.

In 1840 Thirlwall was raised to the see of St David's. The promotion was entirely the act of Lord Melbourne, an amateur in theology, who had read Thirlwall's introduction to Schleiermacher, and satisfied himself of the propriety of the appointment. "I don't intend to make a heterodox bishop if I know it," he said. In most essential points he was a model bishop, and he acquainted himself with Welsh, so as to preach and conduct service in that language. He was not greatly beloved by his clergy, who felt their intellectual distance too great, and were alternately frozen by his taciturnity and appalled by his sarcasm. The great monument of his episcopate is the eleven famous charges in which he from time to time reviewed the position of the English Church with reference to whatever might be the most pressing question of the day—addresses at once judicial and statesmanlike, full of charitable wisdom and massive sense. His endeavours to allay ecclesiastical panic, and to promote liberality of spirit, frequently required no ordinary moral courage. He was one of the four prelates who refused to inhibit Bishop Colenso from preaching in their dioceses, and the only one who withheld his signature from the addresses calling upon Colenso to resign his see. He took the liberal side in the questions of Maynooth, of the admission of Jews to parliament, of the Gorham case, and of the educational conscience clause. He was the only bishop who voted for the disestablishment of the Irish Church, though a scheme of concurrent endowment would have been much more agreeable to him. He would have made an admirable successor to Howley in the primacy, but such was the complexion of ecclesiastical politics that the elevation of the most impartial prelate of his day would have been resented as a piece of party spirit.

Thirlwall's private life was happy and busy. Though never married, he was fond of children and of all weak things except weak-minded clergymen. He had a very judicial mind, and J. S. Mill said he was the best orator he had ever heard. During his latter years he took great interest in the revision of the authorized version of the Bible, and was chairman of the revisers of the Old Testament. He resigned his see in May 1874, and retired to Bath, where he died on the 27th of July 1875. He lies in Westminster Abbey in the same grave as Grote.

As scholar, critic and ecclesiastical statesman Thirlwall stands very high. He was not a great original thinker; he lacked the creative faculty and the creative impulse. His character, with its mixture of greatness and gentleness, was thus read by Carlyle: "A right solid, honest-hearted man, full of knowledge and sense, and, in spite of his positive temper, almost timid."

Thirlwall's *History of Greece* remains a standard book. His *Remains, Literary and Theological*, were edited by J. J. S. Perowne in three volumes (1877–78), two of which are occupied by his charges. His *Letters, Literary and Theological*, with a connecting memoir, were edited by J. J. S. Perowne and L. Stokes (1881). His *Letters to a Friend* (Miss Johnes of Dolaucothy) are a splendid monument to his memory. They were originally published by Dean Stanley, and there is a revised and corrected edition. For a general view of Thirlwall's life and character, see the *Edinburgh Review*, vol. cxliii.; for a picture of him in his diocese, *Temple Bar*, vol. lxxvi.

THIRSK, a market-town in the Thirsk and Malton parliamentary division of the North Riding of Yorkshire, England, 22 m. N.W. by N. from York by the North-Eastern railway. Pop. (1901) 3093. It lies in a fertile plain W. of the Hambleton Hills, on the Codbeck, a small tributary of the Swale. The church of St Mary, entirely Perpendicular, with parvise, chancel, nave, aisles, porch, and tower 80 ft. in height, is one of the most beautiful churches in the Riding. The original work of oak is especially noteworthy. The moat of the ancient castle built by the Mowbrays about 980 remains. The principal modern buildings are the assembly rooms, mechanics' institute, and court-house. Standing in the fertile district of the Vale of Mowbray, the town has an extensive agricultural trade. Agricultural implements are largely manufactured. Iron-founding, engineering, tanning and brick-making are carried on, and there are large flour-mills.

At the time of the Domesday Survey, Thirsk (Treske) was a manor of little importance belonging partly to the king and partly to Hugh, son of Baldric. Soon afterwards it was granted to Robert de Mowbray, who often resided there, and is said to have raised the castle round which the borough grew up. His estates, being forfeited for treason against William Rufus, were restored by Henry I. to Nigel de Albini, Robert's cousin, who took the name of Mowbray. Roger, son of Nigel, took part in the rebellion against Henry II. in 1174, and although he was allowed to retain his estates, his castle at Thirsk was destroyed. The manor remained in his family until the death of John de Mowbray, duke of Norfolk, without issue male in 1475, and after passing through several families was finally sold in 1723 to Ralph Bell, whose descendants thereafter held the manor. Thirsk is first mentioned as a borough in a charter granted by Roger de Mowbray to Newburgh Priory in the reign of Henry II. It was governed by a bailiff elected by the burgesses at the court leet of the lord of the manor, and never received a charter of incorporation. The burgesses were represented in parliament by two members in 1295 and again from 1552–53 to 1832, when by the Municipal Reform Act the number was reduced to one. In 1885 the town was disfranchised. Roger de Mowbray held a market by prescription in Thirsk in the 13th century, and by Camden's time (*c.* 1586) it had become one of the best markets in the North Riding. It is still held by the lord of the manor.

See *Victoria County History: Yorkshire;* William Grainge, *The Vale of Mowbray: a historical and topographical account of Thirsk and its neighbourhood* (1859).

THIRTY YEARS' WAR (1618–1648), the general name of a series of wars in Germany which began formally with the claim of Frederick the elector palatine to the throne of Bohemia and ended with the treaty of Westphalia. It was primarily a religious war and was waged with the bitterness characteristic of such wars, but at the same time political and feudal quarrels were interwoven with the religious question, with the consequence that the armies, considering themselves as their masters' retainers rather than champions of a cause, plundered and burned everywhere, military violence being in no way restrained by expediency. In a war based on the principle *cujus regio ejus religio* it was vain to expect either the professional or the national type of army to display its virtues.

Nature of the struggle.

Fifty years before the outbreak of the war the Convention of Passau had compromised the burning questions of the Reformation, but had left other equally important points as to the secularization of church lands and the consecration of Protestant bishops to the future. Each such case, then, came before the normal government machine—a Diet so constituted that even though at least half of the secular princes and nine-tenths of their subjects were Protestants, the voting majority was Catholic in beliefs and in vested interests. Moreover, the Jesuits had rallied and disciplined the forces of Catholicism, while Protestantism, however firm its hold on the peoples, had at the courts of princes dissipated itself in doctrinal wrangles. Thus, as it was the princes and the free cities, and by no means the mass of the people, that settled religious questions, the strongest side was that which represented conservatism, peace and Catholicism. Realizing this from the preliminary mutterings of the storm, the Protestant princes formed a union, which was promptly answered by the Catholic League. This group was headed by the wise and able Maximilian of Bavaria and supported by his army, which he placed under a soldier of long experience and conspicuous ability, Count Tilly.

The "Union" and the "League" formed.

The war arose in Bohemia, where the magnates, roused by the systematic evasion of the guarantees to Protestants, refused to elect the archduke Ferdinand to the vacant throne, offering it instead to Frederick, the elector palatine. But the aggrandizement of this elector's power was entirely unacceptable to most of the Protestant princes—to John George of Saxony above all. They declared themselves neutral, and Frederick found himself an isolated rebel against the emperor Ferdinand, and little more than the nominal head of an incoherent nobility in his new kingdom.

Bohemian movement.

Even thus early the struggle showed itself in the double aspect of a religious and a political war. Just as the Protestants and their nominee found themselves looked upon askance by the other Protestants, so the emperor himself was unable to call upon Maximilian's Army of the League without promising to aggrandize Bavaria. Indeed the emperor was at first—before Frederick intervened—almost a mere archduke of Austria waging a private war against his neighbours. Only the incoherence of his enemies saved him. They ordered taxes and levies of soldiers, but the taxes were not collected, and the soldiers, unpaid and unfed, either dispersed to their homes or plundered the country-side. The only coherent force was the mercenary corps of Ernst von Mansfeld, which, thrown out of employment by the termination of a war in Italy, had entered the service of the Union. Nevertheless, the Bohemians were conspicuously successful at the outset. Under Count Thurn they won several engagements, and Ferdinand's army under Carl Bonaventura de Longueval, Count Buquoi (1571–1621), was driven back. Thurn appeared before Vienna itself. Moravia and Silesia supported the Bohemians, and the Austrian nobles attempted, in a stormy conference, to wrest from Ferdinand not only religious liberty but also political rights that would have made Austria and Bohemia a loose confederation of powerful nobles. Ferdinand firmly refused, though the deputation threatened him to his face, and the tide ebbed as rapidly as it had flowed. One or two small military failures, and the enormous political blunder of bringing in the elector palatine, sealed the fate of the Bohemian movement, for no sooner had Frederick accepted the crown than Maximilian let loose the Army of the League. Spanish aid arrived. Spinola with 20,000 men from the Low Countries and Franche Comté invaded the Palatinate, and Tilly, with no fears for the safety of Bavaria, was able to combine with Buquoi against the Bohemians, whose resistance was crushed at the battle of the Weisser Berg near Prague (8/18 November 1620). With this the Bohemian war ended. Some of the nobles were executed, and Frederick, the "Winter King," was put to the ban of the Empire.

Defeat of Frederick.

The menace of Spinola's invasion broke up the feeble Protestant Union. But the emperor's revenge alarmed the Union princes. They too had, more or less latent, the tendency to separatism and they were Protestants, and neither in religion nor in politics could they suffer an all-powerful Catholic emperor. Moreover, the alternative to a powerful emperor was a powerful Bavaria, and this they liked almost as little.

There still remained for the armies of Tilly and Buquoi the reduction of the smaller garrisons in Bohemia, and these when finally expelled rallied under Mansfeld, who was joined by the disbanded soldiery of the Protestant Union's short-lived army. Then there began the wolf-strategy that was the distinguishing mark of the Thirty Years' War. An army even of ruffians could be controlled, as Tilly controlled that of the League, if it were paid. But Mansfeld, the servant of a shadow king, could not pay. Therefore "he must of necessity plunder where he was. His movements would be governed neither by political nor by military considerations. As soon as his men had eaten up one part of the country they must go on to another, if they were not to die of starvation. They obeyed a law of their own, quite independent of the wishes or needs of the sovereign whose interests they were supposed to serve." These movements were for preference made upon hostile territory, and Mansfeld was so far successful in them that the situation in 1621 became distinctly unfavourable to the emperor. He had had to recall Buquoi's army to Hungary to fight against Gabriel Bethlen, the prince of Transylvania, and in an unsuccessful battle at Neuhäusel (July 10) Buquoi was killed. Tilly and the League Army fought warily and did not risk a decision. Thus even the proffered English mediation in the German war might have been accepted but for the fact that in the Lower Palatinate a corps of English volunteers, raised by Sir Horace Vere for the service of the English princess Elizabeth, the fair queen of Bohemia, found itself compelled, for want of pay and rations, to live, as Mansfeld lived, on the country of the nearest probable enemy—in their case the bishop of Spire. This brought about a fresh intervention of Spinola's army, which had begun to return to the Low Countries to prosecute the interminable Dutch war. Moreover Mansfeld, having so thoroughly eaten up the Palatinate that the magistrates of Frederick's own towns begged Tilly to expel his general, decamped into Alsace, where he seized Hagenau and wintered in safety.

Predatory armies.

The winter of 1621–22 passed in a series of negotiations which failed because too many interests, inside and outside Germany, were bound up with Protestantism to allow the Catholics to speak as conquerors, and because the cause of Protestantism was too much involved with the cause of the elector palatine to be taken in hand with energy by the Protestant princes. But Frederick and Mansfeld found two allies. One was Christian of Brunswick, the gallant young knight-errant, titular bishop of Halberstadt, queen Elizabeth's champion, and withal, though he called himself *Gottes Freund, der Pfaffen Feind*, a plunderer of peasants as well as of priests. The other was the margrave George Frederick of Baden-Durlach, reputed to be of all German princes the most skilful sequestrator of ecclesiastical lands. In April 1622, while Vere garrisoned the central fortresses of the Palatinate, Mansfeld, Christian and George Frederick took the field against Tilly, who at once demanded assistance from Spinola. The latter, though engaged with the Dutch, sent a corps under his subordinate Cordova. Before this arrived Mansfeld and the margrave of Baden had defeated Tilly at Wiesloch, south of Heidelberg (17/27 April 1622). Nevertheless Tilly's army was not as easily dissolved as one of theirs, and soon the allies had to separate to find food. Then Cordova came up, and Tilly and the Spaniards combined defeated George Frederick at Wimpfen on the Neckar (26 April/6 May). Following up this success, Cordova chased Mansfeld back into Alsace, while Tilly went north to oppose Christian of Brunswick on the Main. On June 10/20 the latter's army was almost destroyed by the League Army at Höchst. Mansfeld, and with him Frederick, had already set out from Alsace to join Christian, but when that leader arrived with only a handful of beaten men, the war was practically at an end. Frederick took Mansfeld and Christian back to Alsace, and after dismissing their troops from his employment, retired to Sedan. Henceforth he was a picturesque but powerless exile, and his lands and his electoral dignity, forfeited by the ban, went to the prudent Maximilian, who thus became elector of Bavaria. Finally Tilly conquered the Palatinate fortresses, now guarded only by the English volunteers.

Fresh combatants in the war.

The next act in the drama, however, had already begun with the adventures of the outlaw army of Mansfeld and Christian. After Höchst, had it not been for them, the war might have ended in compromise. James I. of England was busy as always with mediation schemes. Spain, being then in close connexion with him, was working to prevent the transfer of the electorate to Maximilian, and the Protestant princes of North Germany being neutral, a diplomatic struggle over the fate of the Palatinate, with Tilly's and Cordova's armies opposed in equilibrium, might have ended in a new convention of Passau that would have regulated the present troubles and left the future to settle its own problems. The struggle would only have been deferred, it is true, but meanwhile the North German Protestants, now helpless in an unarmed neutrality, would have taken the hint from Maximilian and organized themselves and their army. As it was, they remained powerless and inactive, while Tilly's army, instead of being disbanded, was kept in hand to deal with the adventurers.

Mansfeld and Christian of Brunswick.

These, after eating up Alsace, moved on to Lorraine, whereupon the French government "warned them off." But ere long they found a new employment. The Dutch were losing ground before Spinola, who was besieging Bergen-op-Zoom, and the States-General invited Mansfeld to relieve it. Time was short and no détour by the Lower Rhine possible, and the adventurers therefore moved straight across Luxemburg and the Spanish Netherlands to the rescue. Cordova barred the route at Fleurus near the Sambre, but the desperate invaders, held together by the sheer force of character of their leaders, thrust him out of their way (19/29 August 1622) and relieved Bergen-op-Zoom. But ere long, finding Dutch discipline intolerable, they marched off to the rich country of East Friesland.

Mansfeld marches to Friesland.

Their presence raised fresh anxieties for the neutral princes of North Germany. In 1623 Mansfeld issued from his Frisian stronghold, and the threat of a visitation from his army induced the princes of the Lower Saxon Circle to join him. Christian was himself a member of the Circle, and although he resigned his bishopric, he was taken, with many of his men, into the service of his brother, the duke of Brunswick-Wolfenbüttel; around the mercenary nucleus gathered many thousands of volunteers, and the towns and the nobles' castles alike were alarmed at the progress of the Catholics, who were reclaiming Protestant bishoprics. But this movement was nipped in the bud by the misconduct of the mercenaries. The authorities of the Circle ordered Christian to depart. He returned to Holland, therefore, but Tilly started in pursuit and caught him at Stadtlohn, where on 28 July/6 August 1623 his army was almost destroyed. Thereupon the Lower Saxon Circle, which, like the Bohemians, had ordered collectively taxes and levies of troops that the members individually furnished either not at all or unwillingly, disbanded their army to prevent brigandage. Mansfeld, too, having eaten up East Friesland, returned to Holland in 1624.

The only material factor was now Tilly's ever-victorious Army of the League, but for the present it was suspended inactive in the midst of a spider's web of European and German diplomacy. Spain and England had quarrelled. The latter became the ally of France, over whose policy Richelieu now ruled, and the United Provinces and (later) Denmark joined them. Thus the war was extended beyond the borders of the Empire, and the way opened for ceaseless foreign interventions. From the battle of Stadtlohn to the pitiful end twenty years later, the decision of German quarrels lay in the hands of foreign powers, and for two centuries after the treaty of Westphalia the evil tradition was faithfully followed.

Foreign intervention.

France was concerned chiefly with Spain, whose military possessions all along her frontier suggested that a new Austrasia, more powerful than Charles the Bold's, might arise. To Germany only subsidies were sent, but in Italy the Valtelline, as the connecting link between Spanish possessions and Germany, was mastered by a French expedition. James, in concert with France, re-equipped Mansfeld and allowed him to raise an army in England, but Richelieu was unwilling to allow Mansfeld's men to traverse France, and they ultimately went to the Low Countries, where, being raw pressed-men for the most part, and having neither pay (James having been afraid to summon parliament) nor experience in plundering, they perished in the winter of 1625. At the same time a Huguenot rising paralysed Richelieu's foreign policy. Holland after the collapse of Mansfeld's expedition was anxious for her own safety owing to the steady advance of Spinola. The only member of the alliance who intervened in Germany itself was Christian IV. of Denmark, who as duke of Holstein was a member of the Lower Saxon Circle, as king of Denmark was anxious to extend his influence over the North Sea ports, and as Protestant dreaded the rising power of the Catholics. Gustavus Adolphus of Sweden, judging better than any of the difficulties of affronting the Empire and Spain, contented himself for the present with carrying on a war with Poland.

Intervention of Christian of Denmark.

Christian IV. raised an army in his own lands and in the Lower Saxon Circle in the spring of 1625. Tilly at once advanced to meet him. But he had only the Army of the League, Ferdinand's troops being occupied with repelling a new inroad of Gabriel Bethlen. Then, like a *deus ex machina*, Wallenstein, duke of Friedland, came forward and offered to raise and maintain an army in the emperor's service. It was an army like Mansfeld's in that it lived on the country, but its exactions were systematic and the products economically used, so that it was possible to feed 50,000 men where Mansfeld and his like had barely subsisted 20,000. This method, the high wages which he paid, and his own princely habits and commanding personality gave it a cohesion that neither a free company nor an army of mere Lower Saxon contingents could ever hope to attain.

Wallenstein raises an army.

In 1625, in spite of Tilly's appeals, Wallenstein did nothing but levy contributions about Magdeburg and Halberstadt, keeping his new army well away from the risks of battle until he could trust it to conquer. It was fortunate for Ferdinand that he did so. Christian IV., who had been joined by Mansfeld and Christian of Brunswick, had in 1626, 60,000 men. Wallenstein and Tilly together had only a very slight numerical superiority, and behind them was nothing. Even the hereditary provinces of Austria were threatening revolt owing to their having to maintain Maximilian's troops (the new elector thus recouping his expenses in the Palatinate war) and Gabriel Bethlen was again in the field. But on the other side the English subsidies failed, and the Protestant armies soon began to suffer in consequence. Tilly opposed Christian IV., Wallenstein Mansfeld. The latter, having stood still about Lübeck and in the outskirts of Brandenburg till the food was exhausted, advanced upon Wallenstein, attacked him in an entrenched position at the Bridge of Dessau and was thoroughly defeated (15/25 April 1626). He then wandered across Germany into Silesia and joined Bethlen. Wallenstein followed up, and by taking up strong positions, compelled Mansfeld and Bethlen to choose between attacking him and starving. So, without a battle, he brought about a truce, whereby Bethlen was disarmed and Mansfeld was required to leave Hungary. Mansfeld and Christian of Brunswick died soon afterwards, the one in Hungary, the other in Westphalia. King Christian, left alone and unable without English subsidies to carry on the war methodically, took the offensive, as Mansfeld had done, in order to live on the Thuringian countryside. But Tilly, with whom Wallenstein had left a part of his army, moved as quickly as the king, brought him to action at Lutter-am-Barenberge in Brunswick and totally defeated him (17/27 August).

Defeat and death of Mansfeld.

With this, armed opposition to Tilly and Wallenstein in the field practically ceased until 1630. But there was enough danger to prevent the disbandment of their armies, which continued to live on the country. In the intervening years the balance of forces, political and military, was materially altered. France opposed Spain and the emperor in Italy with such vigour as Huguenot outbreaks permitted, England quarrelled with France, but yet like France sent subsidies to the North German Protestants. Gustavus held his hand, while Christian slowly gave up fortress after fortress to Tilly. Wallenstein, returning from the campaign against Gabriel Bethlen, subdued Silesia, where a small part of Mansfeld's army had been left in 1626, and afterwards drove Christian's army through Jutland (1627). But Wallenstein, with his dreams of a united Germany free in conscience and absolutely obedient to the emperor, drifted further and further away from the League. Ferdinand thought that he could fulfil the secular portion of Wallenstein's policy while giving satisfaction to the bishops. The princes and bishops of the League continued to oppose any aggrandizement of the emperor's power at their expense and to insist upon the resumption of church lands. In this equilibrium the North German Protestant cities were strong enough to refuse to admit Wallenstein's garrisons. In 1628 Wallenstein, who had received the duchy of Mecklenburg on its rightful lord being put to the ban for his share in the Danish war, began to occupy his new towns, and also to spread along the coasts, for his united Germany could never be more than a dream until the possibility of Danish and Swedish invasions was removed. But the Hanse towns rejected his overtures, and Stralsund, second-rate seaport though it was, absolutely refused to admit a garrison of his wild soldiery. The result was the famous siege of Stralsund (February to August 1628), in which, with some slight help from oversea, the citizens compelled the hitherto unconquered Wallenstein army to retire. The siege was, as the result proved, a turning-point in German history. The emperor's policy of restoring order had practically universal support. But the instrument of the restoration was a plundering army. Even this might have been borne had Wallenstein been able to give them, as he wished, not only peace but religious freedom. But when Christian signed the peace of Lübeck, and the Edict of Restitution (1629) gave back one hundred and fifty northern ecclesiastical foundations to the Catholics, men were convinced that one ruler meant one religion. Rather than endure this the North Germans had called in Gustavus Adolphus, and, just as Gustavus landed, the resentment of the princes of the League against Wallenstein's policy and Wallenstein's soldiers came to a head, and the emperor was forced to dismiss him. His soldiers were taken over by Tilly, and for the moment he disappeared from the scene.

Lull in the struggle.

Siege of Stralsund.

Gustavus Adolphus of Sweden.

A thoroughly trained army, recruited from good yeomen and good soldiers of fortune, paid good wages, and led by a great captain, was a novelty in war that more than compensated for Tilly's numerical superiority. Gustavus, however, after landing at Peenemünde in June, spent the rest of the year in establishing himself firmly in Mecklenburg and Pomerania, partly for military reasons, partly in view of a future Swedish hegemony of the Baltic, and most of all in order to secure the active support of the more important Protestant princes, so as to appear as an auxiliary rather than a principal in the German conflict. First the old duke Bogislav of Pomerania, then George William of Brandenburg joined him, very unwillingly. He was soon afterwards allied with France, by the treaty of Bärwalde (January 1631). John George of Saxony, still attempting to stifle the war by his policy of neutrality, sent a last appeal to Vienna, praying for the revocation of the Edict of Restitution. Meanwhile Tilly had marched into north-eastern Germany. On the 19/29 March 1631, the old general of the League destroyed a Swedish garrison at New Brandenburg, and although Gustavus concentrated upon him with a swiftness that surprised the old-fashioned soldiers, Tilly wasted no time in manoeuvres but turned back to the Elbe, where his lieutenant Pappenheim was besieging Magdeburg. This city had twice defied Wallenstein's attempts to introduce a garrison, and it was now in arms against the League. But John George, their prince, had not yet decided to join Gustavus. The latter, as yet without active allies, thought it impossible to go forward alone, and could only hope that his sudden and brilliant storm (3/13 April) of Frankfurt-on-Oder[1] would bring back Tilly from the Elbe. But the hope was vain. Tilly and Pappenheim pressed the siege of Magdeburg, and although the citizens, directed by Swedish officers, fought desperately the place was stormed, sacked and burnt on the night of the 10th of May 1631, amidst horrors that neither of the imperialist generals was able to check, or even to mitigate. The Catholics rejoiced as though for another St Bartholomew's day, the Protestants were paralysed, and even Gustavus, accused on all hands of having allowed the Magdeburgers to perish without giving them a helping hand, sorrowfully withdrew into Pomerania. But Tilly, in spite of Pappenheim's remonstrances, turned westward against Hesse-Cassel and other minor principalities whose rulers had declared for Gustavus. The king of Sweden, thereupon, clearing away the remaining League garrisons, on the Oder, advanced to Werben (at the junction of the Elbe and the Havel), where the army entrenched itself, and, in spite of sickness and famine, stoically awaited the attack. The desired result was achieved. At the end of July Tilly, returning from the west before he had accomplished its reduction, made his appearance and was twice repulsed (13/23 and 18/28 July), losing 6000 men out of 22,000. Moreover, Ferdinand having in his moment of triumph flatly rejected John George's appeal against the Edict, Saxony took up arms. Thereupon Tilly, turning away from Gustavus's entrenchments, invaded Saxony, being reinforced *en route* by 20,000 men from Italy (the war there being left to the Spaniards). The elector at once made an alliance with the Swedes.

Sack of Magdeburg.

[1] In which he exacted life for life and plunder for plunder in return for the slaughter at New Brandenburg.

Then Gustavus advanced in earnest. Tilly had taken no measures to hold him off while the invasion of Saxony was in progress, and he crossed the Elbe at Wittenberg. 16,000 Saxons joined the 26,000 Swedes at Düben, and some of the western Germans had already come in. Tilly had just captured Leipzig, and outside that place, carried away by Pappenheim's enthusiasm, he gave battle on the 7/17 September to the now superior allies. The first battle of Breitenfeld (*q.v.*) was a triumphant success for Gustavus and for the new Swedish system of war, such a battle as no living soldier had seen. The raw Saxons, who were commanded by Arnim, once Wallenstein's lieutenant, were routed by Tilly's men without the least difficulty, and the balance of numbers returned again to the imperialist side. But the veterans of the League army were nevertheless driven off the field in disorder, leaving 6000 dead. Tilly himself was thrice wounded, and only the remnant of his own faithful Walloon regiments remained with him and bore him from the field.

Battle of Breitenfeld.

All Protestant Germany hailed Gustavus as the liberator. Wallenstein, glad of the defeat of the Catholic army, proposed to co-operate with the Swedes. John George, the Swedish general Horn and the Swedish chancellor Oxenstierna united in advising Gustavus to march straight upon Vienna. Richelieu, who desired to humble Ferdinand rather than to disestablish the power of the Catholic princes, was of the same mind. But Gustavus deliberately chose to move into South Germany, there to relieve the Protestants oppressed by Maximilian, to organize the cities and the princes in a new and stronger Protestant Union, the *Corpus Evangelicorum*, and to place himself in a country full of resources whence he could strike out against the emperor, Tilly, and the Rhine Spaniards in turn. To the Saxons he left the task of rousing the Bohemian Protestants, perhaps with the idea of thoroughly committing them to the war upon Ferdinand. The Swedish army pushed on through Halle, Erfurt, Würzburg to Mainz, where in the middle of the "Pfaffengasse," the long lane of bishoprics and abbacies along the Main and the Rhine, it wintered in luxury. The Palatinate was reorganized under Swedish officials and the reformed religion established again. In March 1632 the campaign was resumed. Nuremberg and Donauwörth welcomed Gustavus. Tilly's army, rallied and re-organized for the defence of Bavaria, awaited him on the Lech, but after a fierce battle the passage was forced by the Swedes (4/14 April) and Tilly himself was mortally wounded. Augsburg, Munich and all the towns and open country south of the Danube were occupied without resistance. At the same time John George's army entered Prague without firing a shot.

Strong position of Gustavus Adolphus.

The emperor had now either to submit or to reinstate Wallenstein. Wallenstein demanded as the price of his services the reversal of the Edict, and power to dethrone every prince who adhered to the Swedes. His terms were accepted, and in April 1632 he took the field as the emperor's *alter ego* with a new army that his recruiters had gathered in a few weeks. He soon expelled the Saxons from Bohemia and offered John George amnesty and the rescinding of the Edict as the basis of peace. The elector, bound by his alliance with Gustavus, informed the Swedish king of this offer, and a series of negotiations began between the three leaders. But John George had too much in common with each to follow either Wallenstein or Gustavus unreservedly, and the war recommenced. Gustavus's first danger was on the Rhine side, where Pappenheim, aided by the Spaniards, entered the field. But Richelieu, the half-hearted enemy of distant Catholic princes, was a vigorous enough opponent of Spain on his own frontier, and Gustavus was free in turn to meet Wallenstein's new army of 60,000, composed of the men immortalized by Schiller's play, excellent in war and in plundering, destitute of all home and national ties, and owning allegiance to its general alone. While Gustavus in Franconia was endeavouring with little success to consolidate his *Corpus Evangelicorum* Wallenstein came upon the scene. Gustavus, as soon as his Rhine detachments had rejoined, offered him battle. But as in 1625 Wallenstein would risk no battle until his army had gained confidence. He entrenched himself near Fürth, while Gustavus camped his army about Nuremberg and a contest of endurance ensued, in which the Swedes, who, although they had learned to plunder in Bavaria, were kept rigidly in hand, fared worse. Wallenstein, aided by his superiority in irregular cavalry, was able to starve for three days longer than the king, and at last Gustavus furiously attacked the entrenchments (battle of the Alte Veste, 24 August/3 September, 1632) and was repulsed with heavy losses. Thereupon Gustavus retired, endeavouring in vain to tempt Wallenstein out of his stronghold by making his retreat openly and within striking distance of the imperialists. Wallenstein had other views than simple military success. Instead of following Gustavus, who first retired north-westward and then returned to the Danube at Ingolstadt, he marched into Saxony, his army plundering and burning even more thoroughly than usual in order to force the Saxons into peace. Gustavus followed with the swiftness that was peculiar to the Swedish system, and his detachments on the Main under Bernhard of Saxe-Weimar having secured the road through Thuringia, he concentrated at Erfurt when Wallenstein had scarcely mastered Leipzig. But it was now late in the season, and Wallenstein, hoping to spin out the few remaining weeks of the campaign in an entrenched position, allowed Pappenheim, who had joined him, to return towards the Weser country, where, as in many other districts, spasmodic minor campaigns were waged by local forces and small detachments from the lesser bodies. Within forty-eight hours Pappenheim was called back. Gustavus, without waiting for Arnim's Saxons to join him, had suddenly moved forward, and on the 6/16 November the battle of Lützen (*q.v.*) was fought, a battle as fierce even as Breitenfeld. Gustavus and Pappenheim were slain, and Wallenstein's army, yielding to Bernhard's last attack, retreated.

Wallenstein returns to the imperial service.

The lines of Nuremberg.

Battle of Lützen.

The fall of Gustavus practically determined the intervention of France, for Richelieu supported all electors, Catholic or Protestant, against the central power at Vienna as part of his anti-Spanish policy, and French assistance was now indispensable to the Protestants. For although Lützen was a victory and the Protestant circles formed the League of Heilbronn in April 1633, the emperor was really in the ascendant. John George of Saxony, uneasy both at the prospect of more foreign armies in Germany and at the expressed intention of Bernhard to carve out a principality for himself, needed but little inducement to make peace. But the tragedy of Lützen was soon to be followed by the tragedy of Eger. Wallenstein, gradually forming the resolve of forcing peace on Germany with his army, relaxed his pressure on Saxony, and drawing Arnim's army out of Silesia to protect Dresden, he flung himself upon the Swedish garrisons in Silesia. Winning a victory at Steinau (October 11, 1633) and capturing one town after another, he penetrated almost to the Baltic. But he was recalled to the south-west before his operations had had any effect. The Swedish army, under Bernhard, Horn and Banér, had before the formation of the League of Heilbronn returned to the Palatinate, and while Horn and Banér operated against an imperial army under Aldringer in the Neckar country, Bernhard took Regensburg from Maximilian's army. But it was now late in the year and Wallenstein was intent upon peace. With this object he endeavoured to secure the higher officers of the army, but these were gradually won over by Spanish emissaries; the emperor, having decided to continue the war in alliance with Spain, dismissed his general for the second time. Wallenstein then openly attempted to unite the Swedish, Saxon and other Protestant armies with his own, so as to compel all parties to make peace. But his army would not follow, the *coup d'état* failed, and Wallenstein was murdered at Eger (15/25 February 1634).

League of Heilbronn.

Dismissal and murder of Wallenstein.

All unity, Catholic or Protestant, died with him, and for the next fourteen years Germany was simply the battle-ground of French, Spanish, Austrian and Swedish armies, which, having learned the impunity and advantages of plunder in the school of Mansfeld and Wallenstein, reduced the country to a state of misery that no historian has been able to describe, save by detailing the horrors of one or other village among the thousands that were ruined, and by establishing the net result that Germany in 1648 was worse off than England in 1485, so much worse that while England was the healthier for having passed through the fever of the Wars of the Roses, Germany remained for 150 years more in the stillness of exhaustion.

Success was for the present with the emperor and Spain. Gallas, now appointed to Wallenstein's place, was Aldringer's companion from boyhood, whereas Bernhard, the Rupert of the German war, disagreed with Horn. Under the leadership nominally of the king of Hungary, Ferdinand's heir, but really of Gallas, the army recaptured Regensburg and Donauwörth, and when the Spanish Cardinal Infante joined them with 15,000 men on his way from Italy to the Netherlands, they were invincible. Bernhard attacked them in an entrenched position at Nördlingen (27 August/6 September 1634) and was beaten with a loss of 17,000 men to 2000 of the defenders.

Battle of Nördlingen.

Nördlingen was to the Swedes what Malplaquet was seventy-five years later to the Dutch. The model army of Gustavus perished there, and for the rest of the war a Swedish army, except for some advantages of organization and technical form, was intrinsically no better than another. Gallas reconquered the towns in southern Franconia. John George, having obtained from Ferdinand a compromise on the question of the Edict—its complete revocation Wallenstein's death and Bernhard's defeat had made impossible—agreed to the peace of Prague (20/30 May 1635), wherein all that was Protestant in 1627 was to remain so, or if since resumed by the Roman Church to be returned to the Lutherans.

Peace of Prague.

A certain number of princes followed John George's example on the same terms, but those who were excepted by name from the amnesty and those who had to gain or to regain the lands lost before 1627 continued the war. There was now no ideal, no objective, common even to two or three parties. The Catholic claims were settled by compromise. The power of the central authority, save in so far as the army could without starvation make itself successively felt at one place and another, had long disappeared. Gustavus's *Corpus Evangelicorum* as a German institution was moribund since Nördlingen, and Richelieu and the Spaniards stepped forward as the protagonists, the League of Heilbronn and the emperor respectively being the puppets.

The centre of gravity was now the Rhine valley, the highroad between Spanish Italy and the Spanish Netherlands. Richelieu had, as the price of his assistance after Nördlingen, taken over the Alsatian fortresses held by Bernhard, and in May, just before the treaty of Prague was signed, he declared war on Spain. The French army numbered 130,000 men in 1635, and 200,000 in the year after.

Aggressive policy of France.

One army assembled in Upper Alsace for the attack of the Spaniards in Franche Comté; another occupied Lorraine, which had been conquered in 1633; a corps under Henri de Rohan was despatched from the same quarter across Switzerland, doubling itself from soldiers of fortune met with *en route*, to expel the enemy from the Valtelline, and so to cut the route to the Netherlands. Another force, co-operating with the duke of Savoy, was to attack the Milanese. Bernhard was to operate in the Rhine and Main country, French garrisons holding the places of Alsace. Having thus arranged to isolate the Spanish Netherlands, Richelieu sent his main army, about 30,000 strong, thither to join Frederick Henry of Orange and so to crush the Cardinal Infante. This was strategy on a scale hitherto unknown in the war. Tilly, Wallenstein and Gustavus had made war in the midst of political and religious troubles that hung over a confused country. They had therefore made war as they could, not as they wished. Richelieu had unified France under the single authority of the king, and his strategy, like his policy, was masterful and clear. But the event proved that his scheme was too comprehensive. To seize and to hold with an unshakeable grip the neck of the Spanish power when Gallas and the imperialists were at hand was a great undertaking in itself and absorbed large forces. But not content with this Richelieu proposed to strike at each of the two halves of his enemy's power at the same time as he separated them. His forces were not sufficient for these tasks and he was therefore compelled to eke them out, both in Italy and the Netherlands, by working with allies whose interests were not his.

Spain attacked in Italy and the Netherlands.

The army on the Meuse won a victory at Avins, south of Huy, and afterwards joined Frederick Henry in the siege of Maestricht. But the Brabanters and Flemings had in sixty years of warfare parted so far from their former associates over the Waal that the inroad of Frederick Henry's army produced one of those rare outbursts of a momentary "people's war," which occur from time to time in the wars of the 17th and 18th centuries. The effect of it was that Frederick Henry withdrew to his own country, and in 1636 the French northern army had to face the whole of the Cardinal Infante's forces. In Italy the Franco-Piedmontese army achieved practically nothing, the gathering of the French contingent and its passage of the Alps consuming much time. In the Valtelline Rohan conducted a successful mountain campaign, which even to-day is quoted as a model of its kind.[1]

In Alsace and Lorraine, besides the Spaniards, the dispossessed duke of Lorraine was in the field against the French. Neither side was strong enough to prevail completely. Bernhard waged a desultory campaign in Germany, and then, when supplies gave out and Gallas advanced, joined the French. Towards the end of the year his army was taken into the French service, he himself remaining in command and receiving vague promises of a future duchy of Alsace. Gallas's army from Frankfort-on-Main pushed far into Lorraine, but it was late in the season and want of food compelled it to retreat. In eastern Germany the consequences of the peace of Prague were that Saxony, Brandenburg and other states, signatories to the treaty, were *ipso facto* the enemies of those who continued the war. Thus John George turned his arms against the Swedes in his neighbourhood. But their commander Banér was as superior in generalship as he was inferior in numbers, and held the field until the renewal of Gustavus's truce with Poland, which expired in this year, set free a fresh and uncorrupted Swedish corps that had been held ready for eventualities in that country. This corps, under Torstensson, joined him in October, and on the 1st of November they won an action at Dömitz on the Elbe.

Thus Richelieu's great scheme was only very partially executed. The battle of Avins and Rohan's Valtelline campaign, the only important military events of the year, took place outside Germany; within Germany men were chiefly occupied in considering whether to accept the terms of the peace of Prague. But the land had no rest, for the armies were not disbanded.

In 1636 the movements foreshadowed in 1635 were carried out with energy. John George, aided by an imperialist army, captured Magdeburg, drove back Banér to Lüneburg, and extended his right wing (imperialists) through Mecklenburg into Pomerania, where, however, a Swedish force under the elder Wrangel checked its progress. The Saxons then passed over the Elbe at Tangermünde and joined the imperialists, threatening to interpose between Banér and the Baltic. But Banér was too quick for them. He destroyed an isolated brigade of imperialists at Perleberg, and before the Brandenburg contingent could join John George, brought on a general action at Wittstock (24 September/4 October 1636). The elector had 30,000 men against 22,000 and sought to attack both in front and rear. But while his entrenchments defied the frontal attack Banér threw most of his army upon the enveloping force and crushed it.

Battle of Wittstock.

The Swedes lost 5000 killed and wounded, the combined army 11,000 killed and wounded and 8000 prisoners. The prestige of so brilliant a victory repaired even Nördlingen, and many North German princes who were about to make peace took fresh heart.

In the west, though there were no such battles as Wittstock, the campaign of 1636 was one of the most remarkable of the whole war. The Cardinal Infante was not only relieved by the retreat of the Dutch, but also reinforced by a fresh army[2] under a famous cavalry officer, Johann von Weert. He prepared, therefore, to invade France from the north-west. Even though the army that had fought at Avins and Maestricht returned by sea from Holland, the French were too much scattered to offer an effective resistance, and Prince Thomas of Savoy-Carignan and Johann von Weert, the Cardinal Infante's generals, took Corbie, La Capelle, and some other places, passed the Somme and advanced on Compiègne. For a moment Paris was terror-stricken, but the Cardinal Infante, by ordering Prince Thomas not to go too far in case he were needed to repel a Dutch inroad into Belgium, missed his opportunity.

Invasion of France.

Louis XIII. and Richelieu turned the Parisians from panic to enthusiasm. The burghers armed and drilled, the workmen laboured unceasingly at the dilapidated walls, and the old Huguenot marshal, Jacques Nompart, duc de La Force (d. 1642), standing on the steps of the Hôtel de Ville, raised men for the regular army by the hundred. Money, too, was willingly given, and some 12,000 volunteers went to Compiègne, whither Gaston from Orleans, Longueville from Normandy, and Condé, from Franche Comté, brought levies and reinforcements. Thus the army at Compiègne was soon

[1] See Shadwell, *Mountain Warfare*; and Hardÿ de Périni, *Batailles françaises*, vol. iii., for details.

[2] Composed partly of Bavarians, who had fought their way from the Danube to the Weser, partly of Cologne troops who had joined the Bavarians against the Protestants of north-west Germany.

50,000 strong. The army of Lorraine under Duke Bernhard and Louis de Nogaret, Cardinal de La Valette (d. 1639), placed itself at Épinal to prevent any junction between Prince Thomas and the army of Gallas. But Gaston of Orleans, the king's lieutenant at Compiègne, was no more enterprising as a defender of the country than he had been as a rebel and conspirator, and the army itself was only half mobile owing to its rawness and its "trained-band" character, and the Spaniards and Bavarians retired unmolested to oppose Frederick Henry in the Low Countries. They left a garrison in the little fortress of Corbie, which Monsieur's army recaptured in November. The gallantry of the defenders, which bore heavily on the townspeople, was alloyed with a singular trait of professionalism. The time had come for the Cardinal Infante to distribute his forces in winter quarters, and the garrison of Corbie, it is said, surrendered in good time in order not to be omitted in the allotment of comfortable billets in Belgium.

War in Lorraine and Burgundy.

During the episode of Corbie another storm burst on the eastern frontier of France. The prince of Condé, governor of Burgundy, had in the spring entered Franche Comté and besieged Dôle, but the inhabitants as well as the Spanish troops vigorously opposed him, and his army ultimately went to swell that of Gaston. But, although Duke Charles IV. was active in repossessing himself of Lorraine, Gallas with the main imperialist army[1] stood still in Lower Alsace during the summer. At first he had to await the coming of the nominal commander, Ferdinand's son, but afterwards, when heavy detachments from the defending armies had gone to Compiègne, Gallas himself missed his opportunity. It was not until September that he joined the duke of Lorraine, and later still when he made his inroad into Burgundy. He took a few small towns, but Dijon and the entrenchments of Bernhard's army there defied him, and his offensive dwindled down to an attempt to establish his army in winter quarters in Burgundy, an attempt of which the heroic defence of the little town of St Jean-de-Losne sufficed to bring about the abandonment. Charles IV., however, continued a small war in Lorraine with some success.

War in Italy.

In Italy the duke of Savoy with his own army and a French corps under Créqui advanced to the Ticino, and an action in which both sides lost several thousand men was fought at Tornavento a few miles from the future battlefield of Magenta, to which in its details this affair bears a singular resemblance (June 22, 1636). But the victory of the French was nullified by the refusal of Victor Amadeus, for political reasons, to advance on Milan, and Rohan, who had come down from the Valtelline to co-operate, hastily drew back into his stronghold. On the edges of the western Pyrenees a few towns were taken and retaken.

The campaign of 1637, on the French and Spanish side, was not productive of any marked advantage to either party. From Catalonia a Spanish army invaded Languedoc, but was brought to a standstill in front of the rocky fortress of Leucate and defeated with heavy losses by the French relieving army under Schomberg, duc d'Halluin. In Italy nothing was done. In the Valtelline the local regiments raised by Rohan mutinied for want of pay and Rohan had to retire to France. On the Low Countries frontier the cardinal de La Valette captured Câteau Cambrésis, Landrecies and Maubeuge. The deaths of Ferdinand II., the landgrave of Hesse-Cassel, the duke of Savoy and the duke of Mantua, which occurred almost simultaneously, affected the political foundations of the war but little. The balance, such as it was, however, was unfavourable to France, for the duchess of Mantua went over to the imperialists and the duchess of Savoy was opposed by the princes of her house. On the other hand, Ferdinand III., in spite of Spain, had to concede more power to the electors as the price of the imperial dignity.

War on the Rhine.

On the Rhine and in the adjacent countries Johann von Weert, returning from Belgium with his Bavarians, captured Ehrenbreitstein, the citadel of Coblenz, and expelled small French detachments from the electorate of Trier, whose ruler, the archbishop, had been put to the ban by the emperor. Then, passing into the Main valley, he took Hanau. The main imperialist army, still under Gallas, had departed from Alsace to the east in order to repair the disaster of Wittstock, and Charles of Lorraine, with his own small force and a detachment under Count Mercy left by Gallas, was defeated by Bernhard on the Saône in June, after which Bernhard advanced vigorously against Piccolomini, the imperialist commander in Alsace, and crossed the Rhine at Rheinau. But soon Piccolomini was joined by Johann von Weert, and Bernhard retired again.

[1] For the first time in the history of western Europe Cossacks appeared on the Rhine. Their march through Germany was marked by extraordinary atrocities. They did not remain long at the front, for their insubordination and misconduct were so flagrant that even Gallas found them intolerable and dismissed them.

War in northern and north-eastern Germany.

In the north-east, the effect of Wittstock proved but transient. The widow of the landgrave of Hesse-Cassel, after an attempt at resistance, agreed to the treaty of Prague. In 1638 Banér after taking Erfurt and Torgau found himself the target of several opponents—the Bavarians under Götz, who had remained on the Weser to subdue Hesse-Cassel when their comrades passed into Belgium in 1635, the beaten army of Wittstock, and a potential Brandenburg contingent. The Saxons did no more than defend their own country, but the imperialists and Bavarians uniting under General Geleen manœuvred Banér out of his strongholds on the Elbe. He retreated on the Oder, but there found, not the expected assistance of Wrangel's Pomeranian army, but Gallas with the main imperial army which had hurried over from the west to cut off the Swedes. Banér escaped only by a stratagem. Deluding Gallas with an appearance of retreat into Poland, he turned northwards, joined Wrangel, and established himself for a time in Pomerania. But Gallas ruined his army by exposing it to an open winter in this desolate country, and at last retired to the Elbe. Pomerania, by the death of the old duke Bogislav, became a bone of contention between rival claimants, and in the prevailing equilibrium of greater powers its fate remained unsettled, while a feeble small war slowly consumed what Wallenstein and Gustavus, Gallas and Wrangel had spared.

Fighting in the Netherlands and Alsace.

In 1638 the French operations in Italy, Belgium and Spain were in the main unsuccessful. In Italy Créqui was killed in an action on the 17th of March, and the Spanish commander in the Milanese, Leganez, advanced to the Sesia and took Vercelli. In the Low Countries Prince Thomas and Piccolomini repulsed in turn the Dutch and the French. In the south Condé led from Bayonne an invading army that was to dictate terms at Madrid, but the fortress of Fontarabia, though invested by land and sea, checked the French until a relieving army arrived and drove Condé in disorder to Bayonne. So angry was King Louis at this failure that Condé's lieutenant-general, the brother of Cardinal de La Valette, was condemned for high treason. But the case was different in Alsace. There Richelieu was more than ever determined to strike at the Spanish power, and there too was Bernhard, who hoped that Alsace was to be his future principality, and under whom served the survivors of Breitenfeld and Nördlingen, now in French pay under the name of the "Weimar Army." After the raid into south Germany Bernhard had wintered about Basle, and began operations by taking a few towns in the Black Forest. He then besieged Rheinfelden. Johann von Weert, however, fell upon him by surprise and drove him away (February 28th). Rohan was amongst the dead on the French side. But Bernhard reassembled his adventurers and invited them to return and beat the imperialists at once. The outcome was the battle of Rheinfelden, in which the redoubtable Weert, who had terrified Paris in 1636, was taken prisoner and his army dissipated (March 3rd). Although the Bavarians in the Weser country hurried south to oppose him, Bernhard took Rheinfelden and Freiburg. Lastly he invested Breisach—the town that, scarcely known to-day, was then the "Key of Alsace." Götz's Bavarians and Charles of Lorraine's army hastened thither, but Bernhard beat them in turn at Wittenweiher (August 9th) and Thann (October 15th), and received the surrender of Breisach, when the garrison had eaten the cats, dogs and rats in the place, on the 17th of December.

Beginning of negotiations for peace.

In the course of 1638 peace negotiations were carried on at Cologne and Hamburg, but the war still dragged on. In the east, 1639 began with Banér's pursuit of the retreating Gallas. Thanks to his skill the Swedish star was again in the ascendant. Banér crossed the Elbe, captured Halle and Freiburg, inflicted a severe defeat on the imperialists at Chemnitz (April 14, 1638), and then after overrunning western Saxony advanced into Bohemia, judging rightly that Bernhard was too much occupied with his prospective duchy to co-operate with him in the south-west. Ferdinand III. sent his brother, the archduke Leopold William, to take command of Gallas's army and sent all available reinforcements to Bohemia. But Banér contented himself, after an unsuccessful attempt upon Prague, with thoroughly eating up the country and, as winter came on, he retired into the Saxon mountains. The other Swedish troops overran Brandenburg and fomented a revolt in Silesia.

France and Spain.

In 1639, as before, Richelieu's attacks on Spain, other than those directed upon Alsace and Baden, were unsuccessful. In the north the French devoted this year, as they had devoted 1637 and 1638, to a methodical conquest of walled towns in view of a future *frontière de fer*. The two objectives selected, Hesdin and Thionville, were far apart, and a covering army to protect both sieges against Piccolomini was posted midway between them. Piccolomini, by a forced march from Liége and Huy through the Ardennes, flung himself upon the besiegers of Thionville before their "circumvallation" was completed, and being greatly superior in numbers he almost annihilated them (June 7, 1639) before the covering or rescuing army had even passed the Argonne. Then, however, Piccolomini, whose troops had bought the victory dearly, stood still for a time, and Hesdin, besieged with much pomp by Richelieu's nephew, La Meilleraye, surrendered on the 29th of June. On the side of the Pyrenees Condé as usual showed himself both unlucky and incapable. In Italy Cardinal de La Valette died, after allowing Prince Thomas to win over Savoy to the emperor's side and seeing every French post except Casale, Chivasso and the citadel of Turin taken by Thomas and Leganez.

His successor was the duc d'Harcourt, called by his men "Cadet-la-Perle" on account of his earrings, but a bold and exceedingly competent soldier. Under him served Turenne, hitherto known only as a younger brother of the duke of Bouillon. Harcourt reviewed his army for the first time late in October. The day after the review he advanced from Carignano to revictual Casale, detaching Turenne as flank-guard to hold off Prince Thomas on the side of Turin. The enterprise was entirely successful, but Thomas and Leganez determined to cut off the French on the return march. Leganez beset a defile on the Chieri-Carignano road (whence the action is called the *Route de Quiers*) while Thomas lay in wait to the north. But Turenne and the flank-guard sharply repulsed the prince, and by hard fighting the French returned safe and victorious (November 29th).

In Alsace Bernhard was carried off by a fever just as he was preparing to fight his way to a junction with Banér. Nevertheless he was fortunate in the opportunity of his death, for his dream of a duchy of Alsace had already brought him into conflict with Richelieu, and their conflict could only have ended in one way. Marshal Guébriant at once took steps to secure his army [1] for the service of France, and Richelieu's officers were placed in charge of the fortresses he had conquered. At the same time the long negotiations between the landgravine of Hesse-Cassel and the various powers ended in her allying herself with France and raising an army in return for a subsidy. Another event of importance in this year was the episode of the Spanish fleet in the Downs. Now that the land route was imperilled the sea communications of Spain and Belgium were brought into use. A squadron sailed from Spain for the Netherlands, and, though it evaded the now powerful French navy, it was driven into English territorial waters by the Dutch. Charles I. of England offered France free access to the victim if France would restore the elector palatine, and offered Spain protection if she would furnish him with funds for his army. Richelieu in reply encouraged the growing opposition to Charles at home, and the Dutch, contemptuous of his neutrality, sailed in and destroyed the fleet at anchor.

Death of Bernhard of Saxe-Weimar and its effects.

Fate of the Spanish fleet.

In 1640 the French still kept up their four wars in Belgium, Germany, Italy and Spain. But the Belgian and Spanish frontiers were no longer directly attacked. On the side of Languedoc there was no further danger, for the foolish imposition of strict military forms, and equally foolish threats to punish those who did not appear at the rendezvous, caused the Catalans, who were already defending themselves against the French both efficiently and vigorously, to turn their arms against the old enemy Castile. In December 1640 Portugal declared herself independent under a king of the house of Braganza. In the Low Countries Louis XIII. himself presided over the siege of the important fortress of Arras, which surrendered on the 8th of August.

In Italy, however, Cadet-la-Perle kept the moral ascendancy he had won in the brave action of the *Route de Quiers*. In April with 10,000 men he advanced from Carignan against the 20,000 Spaniards who were besieging Casale and attacked their line of circumvallation boldly and openly on the 29th of April. He himself on horseback led his stormers over the parapet. Turenne spread out his cavalry in one thin line and, thus overlapping Leganez's cavalry on both flanks and aiding his charges with the fire of his dismounted dragoons, drove it away. The Spanish infantry rearguard was cut off and destroyed, and at the end of the day half of Leganez's army was killed or captive. After this, Harcourt promptly turned upon Prince Thomas, and then followed one of the most remarkable episodes in military history. Thomas, himself defending Turin, was besieging the French who still held the citadel, while Harcourt, at once besieging the town and attempting to relieve the citadel, had, externally, to protect himself against Leganez's army which was reorganized and reinforced from Naples and the Papal States. For long it seemed as though the latter, master of the open country, would starve the small army of Harcourt into submission. But Harcourt's courage and the disunion of his opponents neutralized this advantage. Their general attack of the 11th of July on the French lines was made not simultaneously but successively, and Harcourt repulsed each in turn with heavy losses. Soon afterwards the French received fresh troops and a large convoy. The citadel was relieved and the town surrendered soon afterwards. Leganez retired to Milan, Prince Thomas was allowed to take his few remaining troops to Ivrea, and recognized the duchess's regency.

Casale and Turin.

[1] Forestalling others who desired its services, notably the Winter King's son, who intended to ally himself with Spain and so to force the retrocession of the Palatinate. The war had indeed progressed far since the days of the Protestant Union!

In Germany Banér's course was temporarily checked. The archduke dislodged him from his few remaining posts in Bohemia, and when at last Bernhard's old army, under the duc de Longueville, crossed the Rhine at Bacharach and joined Banér in Thuringia, the Austrians held them in check in the broken country about Saalfeld until the country would no longer support the combined army. The Weimar army then retired to the Rhine valley and Banér to Waldeck, and, in the hope of detaching both George of Lüneburg and the landgravine of Hesse-Cassel from the Swedish alliance, the imperial general wasted their territories, ignoring Banér. After the departure of the Lüneburgers and Hessians, recalled for home defence, the Swedish general could only watch for his opportunity.

The Swedes checked.

This came in the winter months of 1640–41. Negotiations for peace were constantly in progress, but no result seemed to come out of them. The Diet was assembled at Regensburg, the imperial army scattered over north-western Germany. Banér suddenly moved south heading for Ratisbon, for the defence of which the archduke's and all available troops—even Piccolomini's from the upper Rhine—were hurried up by the emperor. The Weimar Army under Guébriant joined the Swedes *en route*, and the combined army reached the objective. But a thaw hindered them and gave the emperor time to concentrate his forces, and after a variety of minor operations Banér's army found itself again in possession of Hesse, Lüneburg, Brunswick, &c. Guébriant's army, however, had again separated from him in order to live, and in May was at Bamberg—even an army of 18,000 could hardly keep the field at this stage of the war. On the 20th of May Banér, worn out by fatigue, died, and after some intrigues and partial mutinies, Torstensson succeeded to the command. The last fortified place held by the Austrians in Lower Saxony, Wolfenbüttel, was now besieged by Torstensson's Swedes and Germans and Guébriant's French and Weimarians, and the archduke and Piccolomini advancing to its relief were defeated outside the walls on the 29th of June. The war had now receded far from Alsace, which was firmly held by France, and no longer threatened even by Charles of Lorraine, who had made his peace with Louis XIII. in the spring, and whose army had followed Guébriant into Germany. The losses of the Germans at Wolfenbüttel caused some of their princes to accept the peace of Prague, but, on the other hand, the new elector of Brandenburg (Frederick William, the Great Elector) gave up the Austrian alliance and neutralized his dominions.

Banér's last successes.

In 1641 Harcourt thoroughly established his position, without much fighting, in Piedmont. In Spain the Catalan and Portuguese insurrections continued and the French occupied Barcelona, but underwent a serious reverse at Tarragona. In the north La Meilleraye captured and held some of the Artois towns, but was driven out of the open country by the superior army of the Cardinal Infante. A formidable conspiracy against Richelieu brought about a civil war in which the king's troops were defeated at La Marfée, near Sedan (the fortress of Turenne's discontented brother, the semi-independent duke of Bouillon), by a mixed army of rebels, Spaniards and Imperialists (July 6th). This, however, led to nothing further and the conspiracy collapsed. Charles of Lorraine having joined the rebels, his newly regained fortresses were reoccupied by the French.

Civil war in France.

In December 1641 there began at Münster and Osnabrück in Westphalia the peace negotiations which, after eight more years of spasmodic fighting, were to close this ruinous war.

In 1642 Torstensson, having cleared up the war for a moment in the north-west, turned upon Silesia, defeated an imperialist corps at Schweidnitz and took some fortresses, but drew back when the archduke and Piccolomini came up with the main Austrian army. In October, however, he was joined by fresh troops from the north-east, crossed the Elbe and besieged Leipzig. The imperialist army, which was joined by the Saxons when their country was again the theatre of war, marched to the rescue. But Torstensson defeated them with enormous loss in the second battle of Breitenfeld [2] (November 2, 1642). But, although the Austrians feared an advance on Vienna itself, the victors waited for the fall of Leipzig and then took up winter quarters. Guébriant had throughout the year operated independently of the Swedes. The Bavarians had advanced into the lower Rhine region in order to support, in concert with the Belgian army of Spain, a fresh outbreak in France (Cinq-Mars' conspiracy). But Lamboy, the Spanish general, was attacked and defeated before Hatzfeldt's Bavarians came up, at Hulst between Kempen and Crefeld (January 17th), whereupon the Bavarians took shelter under the guns of the fortress of Jülich.

Torstensson's victory of Breitenfeld.

On the northern frontier of France Harcourt, the brilliant commander of the Italian army, failed to prevent the Spaniards from capturing Lens and La Bassée, and Guiche, with another army farther east at Le Câtelet, was defeated and routed at Honnecourt (May 26th), saving only 2000 of his 9000 men. But Francisco de

[2] The emperor executed all the officers and every tenth man of the regiment in which the panic began.

Melo, the Cardinal Infante's successor, did not profit by his victory, turning back instead to oppose the Dutch and Guébriant. In Italy Thomas of Savoy and his brother, submitting to the regency of the duchess, led her troops in concert with the French against the Spaniards of the Milanese, and took Tortona. Louis himself conquered Roussillon, Richelieu crushed the conspiracy of Cinq Mars by executing its leaders, and Marshal de la Motte-Houdencourt held Catalonia and defeated Leganez at Lerida (October 7th).

Before the next campaign opened Louis and Richelieu were dead. One of the last acts of the king was to designate the young duc d'Enghien, son of the incapable Condé, as general of his northern army. Harcourt had strangely failed, Guébriant was far away, and the rest of the French marshals were experienced but incapable of commanding an army. Yet it was no small matter to put in their place a youth of twenty-one, who might prove not merely inexperienced but also incompetent. But Enghien's victory was destined to be the beginning for the French army of a long hegemony of military Europe.

The Duc d'Enghien.

Melo had selected the Meuse route for his advance on Paris. On it he would meet only the places of Rocroi and Rethac; these mastered, he would descend upon Paris by the open lands between the Marne and the Oise. He began by a feint against Landrecies, and under cover of this secretly massed his Sambre and Ardennes corps on the Meuse, while Enghien, having the safety of Landrecies in mind, moved to St Quentin. There, however, the young general learned at the same moment that Louis XIII. was dead and that the Spaniards had invested Rocroi. With the resolution and swiftness which was to mark his whole career, he marched at once to offer them battle. Enghien's more experienced counsellors, the generals of the old school, were for delay. To risk the only French army at such a moment would, they said, be madness, and even the fiery Gassion asked, "What will become of us if we are beaten?" But Enghien replied, "That will not concern me, for I shall be dead," and his personality overcame the fears of the doubters. The battle took place on the 19th of May 1643, in a plain before Rocroi, without any marked tactical advantage of ground in favour of either side. Melo's cavalry was routed, and nearly all the infantry, 18,000 men of the best regiments in the Spanish army, the old Low Countries *tercios*, with their general the Conde de Fuentes,[1] a veteran of fifty years' service, in their midst, stood their ground and were annihilated. 8500 were dead and 7000 prisoners. Two hundred and sixty colours and standards went to grace Nôtre Dame.

Battle of Rocroi.

But even Rocroi, under the existing conditions of warfare, was decisive only in so far as, by the destruction of Spain's superiority in Belgium, it saved France from further inroads from the north. Enghien indeed followed up the débris of Melo's army beyond the Sambre, but on the Rhine Guébriant had marched away from the region of Cologne into Württemberg, and there was nothing to prevent the imperialists in the north-west from joining Melo. The thorough establishment of the French on the Rhine and the need of co-operating with the Swedes was considered by the young general to be more important than fighting Melo in front of Brussels, and in spite of the protests of the Regent and Mazarin, he decided to attack Thionville. Taking a leaf out of Melo's book, he threatened Brussels in order to draw all the defenders thither, and then suddenly turned eastward. Enghien arrived on June 18th, a corps from Champagne had already reached the place on the 16th, and on the 8th of August Thionville surrendered. The small fortress of Sierck followed suit (September 8th).

Surrender of Thionville.

Guébriant meanwhile had attempted without success to cover the French and Protestant posts in Württemberg against the united forces of his old opponents from the lower Rhine (Hatzfeldt's Bavarians) and a fresh Bavarian army under Mercy, and had retired into Alsace. Thither Enghien, before dispersing his army into rest-quarters in October, sent him a corps under Josias Rantzau to enable him to recross the Rhine and to seize winter-quarters in Germany so as to spare Alsace. Guébriant did so, but he was mortally wounded in the siege of Rottweil, a town at the source of the Neckar, and Rantzau, taking over the command, allowed himself to be surprised in the act of dispersing into winter-quarters by Charles of Lorraine (who had again changed sides and now commanded his own, Hatzfeldt's and Mercy's armies[2]). At Tuttlingen on the headwaters of the Danube, Rantzau was taken prisoner with the greater part of his army of 12,000 men (November 24th), and the rest hurriedly fell back into Alsace.

In the east the campaign had as usual turned more upon subsistence than upon military operations. Torstensson, by his halt before Leipzig after Breitenfeld, had given the emperor a whole winter in which to assemble a new army. The hereditary provinces, as the devastations of war approached their own borders, willingly supplied a force of 12,000 men, which under Piccolomini manoeuvred for a while to the west of Dresden. But Piccolomini was replaced by Gallas, who, though cherishing visionary schemes of uniting Hatzfeldt's troops and Götz's Cologne-Bavarian-North German army with his own for a decisive blow, had in fact to fall back through Bohemia. The Swedes followed. Taking the small towns and avoiding the large places, Torstensson swept through Bohemia and Moravia, his steps dogged through the devastated country by Gallas, until he reached Brünn. Thence, however, he suddenly retreated to the shores of the Baltic. Christian of Denmark had declared war on Sweden, and threatened to isolate the Swedish forces in Germany. Torstensson, therefore, wintered in Holstein, Gallas, unable to follow him through districts already eaten up, in Saxony. In Italy and Spain there was no event of any importance.

Torstensson against Gallas.

In 1644 Gaston of Orleans, with La Meilleraye and Gassion under him, began the conquest of the Dunkirk region, capturing Gravelines in July. Melo, having no army to oppose them, remained inactive. In Italy Prince Thomas and Marshal Plessis-Praslin undertook nothing serious, while in Spain La Motte-Houdencourt lost Lerida, and was imprisoned by Mazarin in consequence. But the Rhine campaign is memorable for the first appearance of Turenne at the head of an army, and for the terrible battle of Freiburg.

The war in the Netherlands and in Italy.

The momentary combination of forces on the other side that had ruined Guébriant's expedition soon broke up. Hatzfeldt was called by the emperor to join Gallas, Charles of Lorraine wandered with his mercenaries to the Low Countries, and Mercy's Bavarians alone were left to oppose Turenne, who spent the first months of the year in restoring discipline and confidence in the shaken Weimar Army. But Mercy was still considerably superior in strength, and, repulsing Turenne's first inroad into the Black Forest, besieged Freiburg. Turenne made one cautious attempt at relief, then waited for reinforcements. These came in the shape of Enghien's army, and Enghien as a prince of the blood took over the supreme command. But both armies together numbered hardly 17,000 men when Enghien and Turenne united at Breisach on the 2nd of August. On the 3rd, although Freiburg had meantime surrendered, they crossed the Rhine and attacked Mercy's position, which was of great natural and artificial strength, in front and flank. Three separate battles, which cost the Bavarians one-third of their force and the French no less than half of theirs, ended in Mercy's retreat (see FREIBURG) on the 10th of August. Enghien did not follow him into the mountains, but having assured himself that he need not fear interference, he proceeded to the methodical conquest of the middle Rhine fortresses (Philippsburg, Heidelberg, Mannheim, Mainz, &c.), and returned with his own army to the Moselle, leaving Turenne and the Weimar Army at Spire.

Battles around Freiburg.

In the east, or rather in the north, a desultory campaign was carried on during 1644 between Torstensson and the younger Wrangel, on the one side, the Danes and Gallas on the other, and in the end Gallas retreated to Austrian territory, so completely demoralized that for want of supervision his army dwindled on the way from 20,000 men to 2000. Torstensson followed him, having little to fear from the Danes. Meanwhile the prince of Transylvania, George Rakóczy, playing the part of Gabriel Bethlen his predecessor, made war upon the emperor, who not being able on that account to send fresh troops against Torstensson, called upon Hatzfeldt, as above mentioned, to reform the wrecks of Gallas's army on the nucleus of his own. Maximilian of Bavaria sent most of his own troops under Weert on the same errand—hence Mercy's defeat at Freiburg. But Torstensson pressed on by Eger, Pilsen and Budweis towards Vienna, and on the 24 February/6 March 1645 he inflicted a crushing defeat on Götz, Weert and Hatzfeldt at Jankau near Tabor. Götz was killed and half of his army dead or captive. In his extremity Ferdinand offered part of Bohemia and Silesia to Maximilian in return for soldiers. But the Bavarian ruler had no soldiers to give, for Turenne was advancing again from the Rhine.

Battle of Jankau.

At the end of March the Weimar Army was at Durlach, on the 6th of April at Pforzheim. Thence it marched to Heilbronn, and Rothenburg-on-Tauber, when Turenne resolved to go northward in search of supplies and recruits in the territories of his ally and

[1] Paul Bernard Fontaine de Fougerolles, a noble of Franche Comté.

[2] The three "armies" combined were hardly more than 25,000 strong.

cousin the landgravine of Hesse-Cassel. But at this point the army, headed by Bernhard's old colonels, demanded to be put into rest-quarters, and Turenne allowing them to disperse as they wished, was surprised by Mercy and Weert—who brought his courage, if nothing else, back from the field of Jankau—and lost two-thirds of his forces. But Turenne instead of retreating to the Rhine installed himself in the landgravine's country, where he collected reinforcements of Hessians and Swedes, while Enghien hurried up from the Moselle and crossed the Rhine to repair the disaster. The "Army of Weimar" and the "Army of France" joined forces, as in 1644, almost under the eyes of the enemy. Enghien at once pushed forward from Ladenburg, by Heidelberg, Wimpfen, Rottenburg and Dinkelsbühl. But from day to day the balance leaned more and more on the Bavarian side, for Torstensson, after threatening Vienna (April), had drawn off into Moravia without waiting for the dilatory Rakóczy, and the emperor was able to give Maximilian an Austrian corps to be added to Mercy's army. Mercy therefore, after manoeuvring for a time on Enghien's left flank, placed himself in a strong position at Allerheim near Nördlingen, directly barring the way to the Danube. The second battle of Nördlingen (August 3, 1645) was as desperately fought as the first, and had not Mercy been killed at the crisis of the day Enghien would probably have been disastrously defeated. As it was, the young duke was victorious, but he had only 1500 infantry left in rank and file out of 7000 at the end. Soon afterwards Enghien fell ill, and his army returned to France. Turenne, left with a few thousand men only, attempted in vain to hold his ground in Germany and had to make a hasty retreat before the archduke Leopold William, who had meantime made peace with Rakóczy, and, leaving Torstensson's[1] successor Wrangel undisturbed in his Silesian cantonments, brought Gallas's and Hatzfeldt's troops to aid Weert's. Turenne wintered around Philippsburg, almost the only remaining conquest of these two brilliant but costly campaigns. But before he settled down into winter quarters he sent a corps to the Moselle, which dislodged the imperialist garrison of Trier and restored the elector in his archbishopric. In Flanders Gaston of Orleans conquered a number of fortresses, and his army united with that of the Dutch. But the allies separated again almost at once, each to undertake the sieges which suited its own purposes best.

Turenne's Army.

Second battle of Nördlingen.

From Silesia Wrangel passed into Bohemia, where he remained until the forces employed against Rakóczy and Turenne could send help to the imperialists opposed to him. He then drew away into Hesse[2] to support the landgravine of Cassel against the landgrave of Darmstadt, the archduke Leopold William and the Bavarians following suit.

The campaign of 1646 in Hesse up to August was as usual uneventful, each army being chiefly concerned with its food. But at last the archduke retired a little, leaving Turenne and Wrangel free to join their forces. Turenne had no intention of repeating the experiences of Freiburg and Nördlingen. War had by now settled down into the groove whence it did not issue till 1793. It was more profitable to attain the small objects that were sought by manoeuvre than by battle, and the choice of means practically lay between manoeuvring the enemy's army into poor districts and so breaking it up by starvation, and pushing one's own army into rich districts regardless of the enemy's army. The usual practice was the first method. Turenne chose the second.

Turenne's strategy.

Delayed at the opening of the year by orders from Mazarin to stand still—the elector of Bavaria had opened negotiations in order to gain time for the archduke Leopold William to march into the west—Turenne found it impossible to reach Hesse by the short and direct route, and he therefore made a rapid and secret march down the Rhine as far as Wesel, whence, crossing unopposed, he joined Wrangel on the upper Lahn (August 10th). The united armies were only 19,000 strong. Then the imperialists, fearing to be hemmed in and starved between Turenne and the Rhine, fell back to Fulda, leaving the Munich road clear. The interior of Bavaria had not been fought over for eleven years, and was thus almost the only prosperous land in desolated Germany. Turenne and Wrangel marched straight forward on a broad front. On the 22nd of September, far ahead of the pursuers, for whom they left nothing to eat, they reached

[1] Torstensson, suffering from gout and worn out by the campaign, retired after the unsuccessful Vienna raid.

[2] John George of Saxony, seeing that his country was faring worse in a state of open war against Sweden than it would even in the most impotent neutrality, had made a truce with Wrangel on what terms he could obtain.

Augsburg, and for the rest of the year they devastated the country about Munich in order to force Maximilian to make terms. An armistice was concluded in the winter, Maximilian having been finally brought to consent by an ill-judged attempt of the emperor (who feared that Bavaria would go the way of Brandenburg and Saxony) to seduce his army. The French and Swedes wintered in southern Württemberg.

In Flanders, Gaston of Orleans and Enghien took Dunkirk and other fortresses. In Italy, where the Tuscan fortresses were attacked, the French and Prince Thomas their ally were completely checked at first, until Mazarin sent a fresh corps thither and restored the balance. In Catalonia Harcourt underwent a serious reverse in front of Lerida at the hands of his old opponent Leganez, and Mazarin sent Enghien, now Prince of Condé, to replace him.

Last months of the war.

1647 was a barren year. The Low Countries Spaniards, concluding a truce with the Dutch, threw their whole force upon France, but this attack dissipated itself in sieges. In Italy Plessis-Praslin won an unprofitable victory over the viceroy of the Milanese on the Oglio (July 4th). In Spain Condé, resuming the siege of Lerida, was repulsed with even more loss than Harcourt had been the year before, and had to retire upon the mere appearance of a relieving army. In Germany Turenne and Wrangel parted company. The latter returned to Hesse, whence he raided into Bohemia, but was driven back by the imperialists under their new general, Melander-Holzapfel. As the few obtainable supply areas gave out one by one, the Swedes gradually retired almost to the coast, but the imperialists did not follow, swerving into Hesse instead to finish the quarrel of the landgravine and the landgrave. Turenne meanwhile had had to send all the French troops to Luxemburg to help in the defence of northern France against the Spaniard. The Weimar Army had refused to follow him to the Meuse, and mutinied for its arrears of pay. Turenne, however, promptly seized the ringleaders and after a sharp fight disarmed the rest. Thus ignominiously Bernhard's old army vanished from the scene.

In the autumn the elector of Bavaria was reconciled to the emperor and his army re-entered the field. Turenne was therefore sent back to Germany to assist the Swedes. But winter came on before any further inroads could be made into south Germany.

The campaign of 1648 brought the decision at last. Turenne and Wrangel, having refitted their forces and united in Hesse as in 1646, steadily drove back the imperialists and Bavarians, whose 30,000 combatants were accompanied by a horde of nearly 130,000 hangers-on—men, women and children—to the Danube. For a moment, at Nördlingen, the French and the Swedes separated, but they soon reunited, moved on to and beyond the Danube, and at Zusmarshausen (May 17th) catching the enemy in the act of manoeuvring, they destroyed his rear-guard, Melander being amongst the dead. The victors advanced as far as the Inn, but Piccolomini, reorganizing the débris of the Austro-Bavarian army, checked their further progress and even drove them back to the line of the Isar. Meantime, however, the Swedish general Königsmarck, gathering all the scattered forces of his side in Saxony and Silesia, had entered Bohemia and was besieging Prague. This caused the recall of Piccolomini's army, and Turenne and Wrangel invested Munich. But Mazarin ordered the French to retire into Suabia so as not to compromise the peace negotiations at the critical moment, and Wrangel followed suit. Before Königsmarck was in a position to assault Prague news came of peace.

Battle of Zusmarshausen.

Meanwhile in Artois Condé had repulsed the Spanish invasion by his brilliant victory of Lens (August 5th), which was a second Rocroi. After the thanksgiving service for the victory at Nôtre Dame, Mazarin arrested the leaders of the Parlement of Paris, and in a few hours the streets were barricaded and a civil war in progress. This was the Fronde (*q.v.*), which went on for another eleven years.

THISTLE, a name, as generally employed, of vague application, being given to almost any herbaceous plant that is of a spiny character. More strictly, it is applied to the species of *Carduus*. These are Composite herbs with very spiny leaves, and similar bracts surrounding a head of purplish-white, tubular, five-parted flowers seated on a pitted and hairy receptacle. The anthers have appendages both at the apex and at the base, and the style has a ring of hairs at the point of bifurcation of the two stigmas. The fruit is surmounted by a tuft of silky-white hairs. The species, chiefly natives of Europe and Western Asia, are numerous, and some are of great beauty, though, not unnaturally, looked on with disfavour by the farmer. The blessed thistle is *Carduus benedictus*; Lady's thistle, the leaves of which are spotted with white, is *C. marianus*. The common *C. lanceolatus* seems to be the most suitable prototype for the Scots thistle. though that honour is also conferred on an allied plant *Onopordon acanthium*, the cotton thistle, remarkable for its covering of white down, a doubtful native, and on other species. The carline thistle is *Carlina vulgaris*, a member of the same family. as is also the sow-thistle, *Sonchus oleraceus*. The great objection to thistles from an agricultural point of view resides in the freedom with which they produce seed, and in the vigour of their underground growth, which makes their uprooting a matter of difficulty. Partial uprooting may, indeed, in the case of the perennial species, increase the mischief, for each fragment left behind may grow into a distinct plant. Annual species might be kept in check were they cut down before the flowers appear, but unless all the cultivators in a particular district co-operate the efforts of individuals are of little avail. The Artichoke (*q.v.*), *Cynara scolymus*, and Cardoon (*q.v.*) are very near allies of the thistles. The Safflower, *Carthamus*, another thistle, yields a serviceable dye; the Burdock, *Arctium lappa*, a member of the same family, has an edible root; and numerous allied species have medicinal properties.

THISTLEWOOD, ARTHUR (1770–1820), the principal instigator of the Cato Street conspiracy, a plot formed to murder many British ministers in 1820. A son of William Thistlewood, and born at Tupholme in Lincolnshire, young Thistlewood passed his early years in a desultory fashion; he became a soldier and visited France and America, imbibing republican opinions abroad and running into debt at home. Then taking up his residence in London he joined the Spencean Society, a revolutionary body; associated himself with James Watson (d. 1838) and other agitators; and in December 1816 helped to arrange a meeting in Spa Fields, London, which was to be followed by the seizure of the Tower of London and the Bank of England, and by a general revolution. The proposed rising was a dismal failure, but the Habeas Corpus Act was suspended and Thistlewood and Watson were seized, although upon being tried they were acquitted. Becoming more violent Thistlewood formed other plots, talked of murdering the prince of Wales, and was sentenced to a year's imprisonment for challenging the home secretary, Lord Sidmouth, to a duel. After his release in May 1819, having broken away from Henry Hunt and the more moderate reformers, he prepared a new and comprehensive plot. On the 23rd of February 1820, at a time of great distress and during the unrest caused by the death of George III., the cabinet ministers had arranged to dine at the earl of Harrowby's house in Grosvenor Square. Thistlewood knew of the dinner. With some associates he hired a room in the neighbouring Cato Street, collected arms and made ready to fall upon Harrowby's guests. However the authorities had been informed of the plot, probably by one of the conspirators named George Edwards; officers appeared upon the scene and arrested some of the conspirators; and although Thistlewood escaped in the confusion he was seized on the following day. Tried for high treason, Thistlewood and four others were sentenced to death, and were hanged on the 1st of May 1820.

See Sir S. Walpole, *History of England* (1890), vol. i.

THÖKÖLY, IMRE (EMERICH), PRINCE (1657–1705), Hungarian statesman, was born at Késmark on the 25th of September 1657. He lost both parents while still a child. In 1670, fleeing from the dangers of Upper Hungary, where the Protestants and Imperialists were constantly in arms against each other, he took refuge with his kinsman Michael Teleki, the chief minister of Michael Apafy, prince of Transylvania. Here he came into contact with the Magyar refugees, who had great hopes of the high-born, high-gifted youth who was also a fellow sufferer, a large portion of his immense estates having been confiscated by the emperor. The discontent reached its height when Leopold (Feb. 27, 1673) suspended the Hungarian constitution, appointed Johan Gaspar Ampringen dictator, deprived 450 Protestant clergy of their livings and condemned 67 more to the galleys. Encouraged by promises of help from Louis XIV., the Magyars now rose *pro libertate et justitia*, and chose the youthful Thököly as their leader. The war began in 1679. Upper Hungary and the mining towns were soon in Thököly's possession. In 1681, reinforced by 10,000 Transylvanians and a Turkish army under the pasha of Nagyvárad, he compelled the emperor to grant an armistice. On the 15th of June 1682 he married Helen Zrinyi, the widow of Prince Francis Rákóczy I. Thököly's distrust of the emperor now induced him to turn for help to the sultan, who recognized him as prince of Upper Hungary on condition that he paid an anuual tribute of 40,000 florins. In the course of the same year Thököly captured fortress after fortress from the emperor and extended his dominions to the Waag. He refused, however, the title of king offered to him by the Turks. At the two Diets held by him, at Kassa and Tályа, in 1683, the estates, though not uninfluenced by his personal charm, showed some want of confidence in him, fearing lest he might sacrifice the national independence to the Turkish alliance. They refused therefore to grant him either subsidies or a *levée en masse*, and he had to take what he wanted by force. Thököly materially assisted the Turks in the Vienna campaign of 1683, and shared the fate of the gigantic Turkish army. The grand vizier nevertheless laid the blame of the failure on Thököly, who thereupon hastened to Adrianople to defend himself before the sultan. Shortly afterwards, perceiving that the Turkish cause was now lost, he sought the mediation of Sobieski to reconcile him with the emperor, offering to lay down his arms if Leopold would confirm the religious rights of the Magyar Protestants and grant him, Thököly, the thirteen north-eastern counties of Hungary with the title of prince. Leopold refused these terms and demanded an unconditional surrender. Thököly then renewed the war. But the campaign of 1685 was a series of disasters, and when he sought help from the Turks at Nagyvárad they seized and sent him in chains to Belgrade, possibly because of his previous negotiations with Leopold, whereupon most of his followers made their peace with the emperor. In 1686 Thököly was released from his dungeon and sent with a small army into Transylvania, but both this expedition and a similar one in 1688 ended in failure. The Turks then again grew suspicious of him and imprisoned him a second time. In 1690, however, the Turks despatched him into Transylvania a third time with 16,000 men, and in September he routed the united forces of General Heister and Michael Teleki at Zernest. After this great victory Thököly was elected prince of Transylvania by the Keresztenymez Diet, but could only maintain his position against the imperial armies with the utmost difficulty. In 1691 he quitted Transylvania altogether. He led the Turkish cavalry at the battle of Slankamen, and in fact served valiantly but vainly against Austria during the remainder of the war, especially distinguishing himself at Zenta. He was excluded by name from the amnesty promised to the Hungarian rebels by the peace of Karlowitz (Jan. 26, 1699). After one more unsuccessful attempt, in 1700, to recover his principality, he settled down at Galata with his wife. From the sultan he received large estates and the title of count of Widdin. He was buried in the great Armenian cemetery at Nicomedia, but in the course of 1906 his relics were transferred to Hungary.

See *Correspondence of Thököly* (Hung.), ed. by Kálmán Thaly (Budapest, 1896); V. Fraknói, *Papst Innocenz XI. und Ungarn's Befreiung von de Türkenherrschaft* (Freiburg, 1902); *Memoirs of*

Emeric Count Teckely (London, 1693); *Correspondence of Michael Teleki* (Hung.), ed. by S. Gergely (Budapest, 1905–1906). (R. N. B.)

THOLOBATE (Gr. θόλος, a circular structure, dome, and βάσις, a base), the architectural term given to the cylindrical drum on which a dome is raised. In the earlier Byzantine churches, the dome rested direct on the pendentives and the windows were pierced in the dome itself; in later examples, between the pendentive and the dome an intervening circular wall was built, in which the windows were pierced, and this is the type which was universally employed by the architects of the Renaissance, of whose works the best-known examples are those of St Peter at Rome, St Paul's in London, and the churches of the Invalides, the Val de Grace and the Sorbonne in Paris.

THOLOS (θόλος), the term given in Greek architecture to a circular building, with or without a peristyle; the earliest examples are those of the beehive tombs at Mycenae and in other parts of Greece, which were covered by domes built in horizontal courses of masonry. The Tholos at Epidaurus, built by Polycleitus (*c.* 400 B.C.), and the Tholos at Olympia, known as the Philippeion, are the most remarkable examples, and in both cases were covered with a sloping roof and not with a dome.

THOLUCK, FRIEDRICH AUGUST GOTTREU (1799–1877), German Protestant divine, was born at Breslau, on the 30th of March 1799. He received his education at the gymnasium and university of his native town, and early distinguished himself by great versatility of mind and power of acquiring languages. A love of Oriental languages and literature led him to exchange the university of Breslau for that of Berlin, that he might study to greater advantage, and there he was received into the house of the Orientalist Heinrich Friedrich von Diez (1750–1817). He was introduced to pietistic circles in Berlin, and came specially under the influence of Baron Hans Ernst von Kottwitz (1757–1843), who became his "spiritual father," and of the historian Neander. Before deciding on the career of theological professor, he had in view that of a missionary in the East. Meanwhile he was feeling the influence to a certain degree of the romantic school, and of Schleiermacher and Hegel too, though he never sounded the depths of their systems. At length, in his twenty-first year, he finally decided to adopt the academical calling. In 1821 he was *Privatdozent* and in 1823 became professor extraordinarius of theology in Berlin, though he was at the same time active in the work of home and foreign missions. He lectured on the Old and New Testaments, theology, apologetics and the history of the church in the 18th century. In 1821 appeared his first work, *Sufismus, sive theosophia Persarum pantheistica*; following the same line of study he published *Blütensammlung aus der morgenländischen Mystik* (1825) and *Speculative Trinitätslehre des späteren Orients* (1826). His well-known essay on the nature and moral influence of heathenism (1822) was published by Neander, with high commendation, in his *Denkwürdigkeiten*; and his Commentary on the Epistle to the Romans (1824) secured him a foremost place amongst the most suggestive, if not the most accurate, Biblical interpreters of that time. Another work, which was soon translated into all the principal European languages, *Die wahre Weihe des Zweiflers* (1823; 9th ed., with the title *Die Lehre von der Sünde und dem Versöhner*, 1870), the outcome of his own religious history, procured for him the position which he ever after held of the modern Pietistic apologist of Evangelical Christianity. In 1825, with the aid of the Prussian government, he visited the libraries of England and Holland, and on his return was appointed (in 1826) professor ordinarius of theology at Halle, the centre of German rationalism, where he afterwards became preacher and member of the supreme consistorial council. Here he made it his aim to combine in a higher unity the learning and to some extent the rationalism of J. S. Semler with the devout and active pietism of A. H. Francke; and, in spite of the opposition of the theological faculty of the university, he succeeded in changing the character of its theology. This he effected partly by his lectures, particularly his exegetical courses, but, above all, by his personal influence upon the students, and, after 1833, by his preaching. His theological position was that of a mild and large-hearted orthodoxy, which laid more stress upon Christian experience than upon rigid dogmatic belief. On the two great questions of miracles and inspiration he made great concessions to modern criticism and philosophy. The battle of his life was on behalf of personal religious experience, in opposition to the externality of rationalism, orthodoxy or sacramentarianism. Karl Schwarz happily remarks that, as the English apologists of the 18th century were themselves infected with the poison of the deists whom they endeavoured to refute, so Tholuck absorbed some of the heresies of the rationalists whom he tried to overthrow. He was also one of the prominent members of the Evangelical Alliance, and few men were more widely known or more beloved throughout the Protestant churches of Europe and America than he. He died at Halle on the 10th of June 1877. As a preacher, Tholuck ranked among the foremost of his time. As a teacher, he showed remarkable sympathy and won great success. As a thinker he can hardly be said to have been endowed with great creative power.

After his commentaries (on Romans, the Gospel of John, the Sermon on the Mount and the Epistle to the Hebrews) and several volumes of sermons, his best-known books are *Stunden christlicher Andacht* (1839; 8th ed., 1870), intended to take the place of J. H. D. Zschokke's standard rationalistic work with the same title, and his reply to David Strauss's *Life of Jesus* (*Glaubwürdigkeit der evangelischen Geschichte*, 1837). He published at various times valuable contributions towards a history of rationalism—*Vorgeschichte des Rationalismus* (1853–1862), *Geschichte des Rationalismus* (1865), i. and a number of essays connected with the history of theology and especially of apologetics. His views on inspiration were indicated in his work *Die Propheten und ihre Weissagungen* (1860), in his essay on the "Alte Inspirationslehre," in *Deutsche Zeitschrift für christliche Wissenschaft* (1850), and in his *Gespräche über die vornehmsten Glaubensfragen der Zeit* (1846; 2nd ed., 1867).

He also contributed many articles to Herzog's *Realencyklopädie*, and for several years edited a journal (1830–1849), *Literarischer Anzeiger*.

See *Das Leben Tholucks*, by L. Witte (2 vols., 1884–1886); *A. Tholuck, ein Lebensabriss*, by M. Kähler (1877), and the same author's art. "Tholuck," in Herzog's *Realencyklopädie*; "Zur Erinnerung an Tholuck," by C. Siegfried, *Protestantische Kirchzeitung* (1885), No. 45, and 1886, No. 47; Karl Schwarz, *Zur Geschichte der neuesten Theologie* (4th ed., 1869); F. W. F. Nippold's *Handbuch der neuesten Kirchengeschichte*; cf. Philip Schaff, *Germany; its Universities, Theology and Religion* (1857), and the article in the *Allgemeine deutsche Biographie*.

THOMA, HANS (1839–), German painter, was born at Bernau in the Black Forest. Having started life as a painter of clock-faces, he entered in 1859 the Carlsruhe academy, where he studied under Schirmer and Des Coudres. He subsequently studied and worked, with but indifferent success, in Düsseldorf, Paris, Italy, Munich and Frankfort, until his reputation became firmly established as the result of an exhibition of some thirty of his paintings in Munich. In spite of his studies under various masters, his art has little in common with modern ideas, and is formed partly by his early impressions of the simple idyllic life of his native district, partly by his sympathy with the early German masters—particularly with Altdorfer and Cranach. In his love of the details of nature, in his precise (though by no means faultless) drawing of outline, and in his predilection for local colouring, he has distinct affinities with the pre-Raphaelites. Many of his pictures have found their way into two private collections in Liverpool. A portrait of the artist, and two subject pictures, "The Guardian of the Valley" and "Spring Idyll," are at the Dresden Gallery; "Eve in Paradise" and "The Open Valley" at the Frankfort Museum. Other important pictures of his are "Paradise," "Christ and Nicodemus," "The Flight into Egypt," "Charon," "Pietà," "Adam and Eve," "Solitude," "Tritons," besides many landscapes and portraits. He has also produced numerous lithographs and pen drawings, and some decorative mural paintings, notably in a café at Frankfort, and in the music room of Mr Pringsheimer's house in Munich.

THOMAR, a town of central Portugal, in the district of Santarem; on the river Nabão, a tributary of the Zezere, 4 m. from Paialvo railway station, which is 89 m. N.E. of Lisbon by the main line to Oporto. Pop. (1900), 6888. Thomar contains examples of the best Portuguese architecture from the 12th century to the 17th. The ruined castle of the Knights Templar, given to that order in 1159, is said to occupy the site of the ancient Nabantia. On the suppression of the Templars, who had done good service against the Moors, King Diniz of Portugal founded the Order of Christ in 1314. The convent palace of the Knights of Christ includes a church and cloister dating from the 12th century, two cloisters and a chapter-house added in the 15th century by Prince Henry the Navigator, a very fine 16th century church built in the Manoellian or Manueline style by João de Castilho, to which the older church served as a chancel, and other buildings erected later. The convent contains Flemish and Portuguese paintings of the 16th century, of the so-called "Grão Vasco" school. Its aqueduct, 3 m. long, was built 1595–1615. Other interesting buildings are the churches of Santa Maria do Olival, rebuilt in the Gothic style in 1450 on the site of an older Templar foundation; São João Baptista, also Gothic, built in 1490, but with Manoellian additions; Nossa Senhora da Conçeição, Renaissance of 1579; and the palace of Prince Henry the Navigator, restored in the 16th century by Queen Catherine, widow of John III.

THOMAS, ST, one of the twelve apostles. The synoptical Gospels give only his name, associating him in their lists with Matthew (Matt. x. 3; Mark iii. 18; Luke vi. 15); in Acts i. 13 he is coupled with Philip. In the Gospel of John (xi. 16; xiv. 5; xx. 24 seq.; xxi. 2) he appears in a characteristic light, full of personal devotion and ready to die with his Master, but slow to grasp the true significance of the personality of Jesus, and incredulous of the resurrection till direct evidence convinces him of its truth and at the same time of the Divinity of his risen Lord. John translates the Aramaic name or surname Thomas by the Greek equivalent Didymus (twin). Tradition has it that he was the twin brother of a sister Lysias (his parents being Diophanes and Rhoa, and his birthplace Antioch; "XII. Apost. Patriae," in *Chron. Pasch.* ii. 142), or of a brother Eliezer (*Hom. Clem.* ii. 1), or, according to the Syriac *Acta Thomae* (ed. Wright, *Eng. trans.* pp. 155, 180), of Jesus Himself. The last form of the tradition seems to be derived from the name Judas Thomas, which he bears in Edessene legend (cf. Eusebius, *H. E.* i. 13, 10), and implies the identification of Thomas with Judas, the brother of the Lord. The most ancient tradition makes Thomas the evangelist of Parthia (Eus. *H.E.* iii. 1, 1); and at Edessa, which claimed to possess his bones, it was related that their missionary Addai (*Doctrine of Addai*, ed. Phillips, 1876, p. 5), whom Eusebius calls Thaddaeus (*H.E.* i. 13), was sent to them by him. Later tradition, originating with the *Acta Thomae*, and accepted by catholic teachers from the middle of the 4th century, makes him proceed to India and there suffer martyrdom. The Indian king Gundaphar of the *Acta* is, however, certainly identical with the historical Gondophares, whose dynasty was Parthian, though his realm included regions loosely reckoned to India. The Parthian and Indian missions of Thomas may perhaps therefore be regarded as derived from a single tradition, but it is very doubtful whether it is based on any historical facts. The oldest extant tradition is that St Thomas did not suffer martyrdom at all (Heracleon *ap.* Clem. Alex. *Strom.* iv. 9). The best investigation of the traditions connecting St Thomas with India is that by W. R. Philipps (*Indian Antiquary*, 1903, xxxii. 1–15, 145–160). The ingenious conjectures of von Gutschmid (*N. Rhein. Mus.* xix. 161 seq.) and Sylvain Lévi (*Journ. asiatique*, 1897, p. 27 seq.) are greatly weakened by the fact that they do not start from a consideration of the names in their original Syriac form. Bishop Medlycott's *India and the Apostle Thomas* (1905) is wholly uncritical.

The *Acta Thomae*, very imperfectly published by Thilo (1823) and Tischendorf (1851), have been edited in Greek by Bonnet (Leipzig, 1883, 2nd ed., with new matter, 1903), and in the original Syriac, with an English translation, by W. Wright (*Apocryphal Acts*, 2 vols., London, 1871). See also Lipsius, *Die apocryphen Apostelgesch.*, ii. (2nd. ed.) 423–425 (Brunswick); F.C. Burkitt in *Journ. Theol. St.* i. 280 seq., ii. 94. The *Acta* are said by Photius to be a part of the Περίοδοι τῶν ἀποστόλων of the Gnostic Leucius Charinus, but this unknown personage is to be thought of as a collector of Gnostic "Acts of Apostles," rather than as the first author. In spite of extensive Catholic revision, the "Acts of Thomas" form one of the most interesting monuments of Syriac Gnosticism. Internal evidence assigns them with great probability to the school of Bardesanes, and the very ancient allegorical hymn about the soul which is preserved in the Syriac text (p. 274 seq., Eng. trans., p. 238 seq.) is perhaps by Bardesanes himself (cf. Nöldeke in *Z.D.M.G.*, 1871, p. 676). This hymn was translated into the Greek *Acta*, along with the rest of the work (Bonnet, pp. 219–224, *Anal. bolland.* xx. 158–164). It is one of the most remarkable pieces in Syriac literature, and has been edited separately by A. A. Bevan, *Texts and Studies*, v. 3 (Cambridge, 1897). A metrical English version is given in F. C. Burkitt's *Early Eastern Christianity*, p. 218 seq. (London, 1904). (F. C. B.)

"Christians of St Thomas" is a name often applied to the members of the ancient Christian churches of southern India, which claim him as their first founder, and honour as their second founder a certain bishop named Thomas, who is said to have come with some presbyters from Jerusalem to Malabar in A.D. 345.[1] According to their tradition, St Thomas went from Malabar to Mylapur, now a suburb of Madras, where the shrine of his martyrdom, rebuilt by the Portuguese in 1547, still stands on Mt St Thomas, and where a miraculous cross is shown with a Pahlavi inscription which may be as old as the end of the 7th century. We know from Cosmas Indicopleustes that there were Christian churches of Persian (East-Syrian) origin, and doubtless of Nestorian creed, in Ceylon, in Malabar, and at Caliana (north of Bombay) before the middle of the 6th century, and even then St Thomas, the reputed apostle of Persia, may have been their special saint. The ancient churches of southern India never died out or wholly lost their sense of connexion with their mother church, for we find them sending deputies in 1490 to the Nestorian patriarch Simeon, who furnished them with bishops (Assemani, *Bib. or.* iii. 1, 590 seq.). Hard pressed by the Moslems, they welcomed the approach of the Portuguese, but proved by no means tractable to efforts to bring them within the Roman obedience. At length a formal union with Rome was carried through in the synod of Diamper (1599). Syriac was to remain the ecclesiastical language, but the service books were corrected and purified from error. A century and a half of foreign Jesuit rule followed, but the love of independence was not lost. A great schism took place in 1653, and of 200,000 Christians of St Thomas only 400 remained loyal to Rome, though many of their churches were soon won back by the Carmelites. Those who remained independent fell under the influence of the Jacobite Mar Gregorius, styled patriarch of Jerusalem, who reached Malabar in 1665 as an emissary from Ignatius, patriarch of Antioch. From his time the independent Christians have been Jacobites, the counter-efforts of the Nestorians under Mar Gabriel, bishop of Azerbaijan, having apparently come to nothing after his death in 1730. Since the visit of Claudius Buchanan, whose *Christian Researches in Asia* (1811) excited great interest, much has been done for the Christians of South India by English missionary effort, and Anglicans have cultivated friendly relations with the clergy of the independent native church, while discouraging dependence on the Jacobite patriarch of Antioch.

A valuable though tedious and ill-arranged history of the Christians of St Thomas is that by W. Germann, *Die Kirche der Thomaschristen*. (Gütersloh, 1877). See also La Croze, *Histoire du christianisme des Indes* (The Hague, 1724); Alexius de Menezes, *Historia ecclesiae malabaricae* (Latin by F. Raulin, Rome, 1745) (especially for the synod of Diamper); Paulinus a S. Bartholomaeo, *India orientalis christiana* (4to, Rome, 1794); George Milne Rae, *The Syrian Church in India* (Edinburgh and London, 1892).

THOMAS À KEMPIS (*c.* 1380–1471), the name by which the Augustinian canon and writer Thomas Hammerken (Hammerchen, Malleolus) is commonly known. He was born in 1379 or 1380 in the town of Kempen, lying about 15 miles north-west of Düsseldorf, in one of the many patches of territory between

[1] See the sketch in Syriac of the history of the church of Malabar printed and translated by Land, *Anecd. Syr.* i. 24 seq. It was sent to Schaaf at Leiden in 1720 by Mar Gabriel, the last Nestorian bishop in Malabar (see Germann, p. 542).

the Meuse and the Rhine belonging to the archiepiscopal principality of Cologne. "Ego Thomas Kempis," he says in his chronicle of the monastery of Mount St Agnes, "scholaris Daventriensis, ex diocesi Coloniensi natus." His father was a poor hard-worked peasant; his mother "ad custodiam rei domesticae attenta, in opere alacris, in victu sobria, in potu abstemia, in verbo pauca, in factis pudica," as her son fondly says, kept a dame's school for the younger children of the town. John and Gertrude Hammerken had two sons, John and Thomas, both of whom found their way to Deventer, and thence to Zwolle and to the convent of Mount St Agnes. Thomas reached Deventer when he was barely twelve years old, was taught by a dame the beginnings of his learning, and in a few months to his great joy entered the classes of Florentius Radewyn. After the fashion of the time he was called Thomas from Kempen, and the school title, as was often the case then, pushed aside the family name. Thomas Hammerken was forgotten; Thomas à Kempis has become known to the whole Christian world.

This school at Deventer had become famous long before Thomas à Kempis was admitted to its classes. It had been founded by Gerhard Groot (*q.v.*), a wealthy burgher who had been won to pious living mainly through the influence of Ruysbroeck, the Flemish mystic. It was at Deventer, in the midst of this mystical theology and hearty practical benevolence, that Thomas à Kempis was trained. Gerhard Groot was his saintly ideal. Florentius Radewyn and Gerhard's other early disciples were his heroes; their presence was his atmosphere, the measure of their lives his horizon. But he was not like them; he was not an educational reformer like Radewyn, nor a man of affairs like Gerhard. He liked books and quiet corners all his days, he says; and so, when conviction of sin and visions of God's grace came to him in the medieval fashion of a dream of the anger and forgiveness of the Virgin, Florentius told him that a monk's life would suit him best, advised him to join the Augustinian order, and sent him to Zwolle to the new convent of Mount St Agnes, where his brother John was prior. Thomas was received there in 1399, he professed the vows in 1407, received priest's orders in 1413, became sub-prior in 1425 and died on the 8th of August 1471, being ninety-one years old.

The convent of Mount St Agnes was poor, and most of the monks had to earn money to support their household by copying MSS. Thomas was a most laborious copyist: missals, books of devotion and a famous MS. Bible were written by him. He also wrote a large number of original writings, most of them relating to the convent life, which was the only life he knew. He wrote a chronicle of the monastery and several biographies—the life of Gerhard Groot, of Florentius Radewyn, of a Flemish lady St Louise, of Groot's original disciples; a number of tracts on the monastic life—*The Monk's Alphabet*, *The Discipline of Cloisters*, *A Dialogue of Novices*, *The Life of the Good Monk*, *The Monk's Epitaph*, *Sermons to Novices*, *Sermons to Monks*, *The Solitary Life*, *On Silence*, *On Poverty*, *Humility and Patience*; two tracts for young people—*A Manual of Doctrine for the Young*, and *A Manual for Children*; and books for edification—*On True Compunction*, *The Garden of Roses*, *The Valley of Lilies*, *The Consolation of the Poor and the Sick*, *The Faithful Dispenser*, *The Soul's Soliloquy*, *The Hospital of the Poor*. He also left behind him three collections of sermons, a number of letters, some hymns and the famous *Imitatio Christi* (though his authorship of this has been disputed). These writings help us to see the man and his surroundings, and contemporary pious records make him something more than a shadow. We see a real man, but a man helpless anywhere save in the study or in the convent—a little fresh-coloured man, with soft brown eyes, who had a habit of stealing away to his cubiculum whenever the conversation became too lively; somewhat bent, for it is on record that he stood upright when the psalms were chanted, and even rose on his tiptoes with his face turned upwards; genial, if shy, and occasionally given to punning, as when he said that he preferred Psalmi to Salmones; a man who perhaps led the most placid uneventful life of all men who ever wrote a book or scribbled letters. It was not that he lived in uneventful times: it is impossible to select a stormier period of European history, or a period when the stir of the times made its way so well into the obscurest corners. Bohemia, Huss leading, was ablaze in revolt at one end of Europe; France and England, then France and Burgundy, were at death-grips at the other. Two popes anathematized each other from Avignon and from Rome, and zealous churchmen were at their wit's end to concoct ways and means, by general councils of Constance and Basel and otherwise, to restore peace to a distracted church, and to discipline the clergy into decent living. But Thomas knew nothing about all this. He was intent on his copying, on his little books, and on his quiet conversations. His very biographies are colourless. He had not even the common interest in the little world coming up to the convent gate which most monks may be supposed to have. His brethren made him oeconomiae prefectus, but he was too "simple in worldly affairs" and too absent-minded for the post, and so they deposed him and made him sub-prior once more. And yet it is this placid kindly fresh-coloured old man who has come down to us as the author of that book the *Imitation of Christ*, which has been translated into more languages than any other book save the Bible, and which has moved the hearts of so many men of all nations, characters and conditions of life.

On the controversy as to the author of the *Imitatio*, see the article IMITATION OF CHRIST. See also James Williams, *Thomas of Kempen* (1910). The classical edition of the works of Thomas à Kempis by Sommalius—*Thomas Malleoli à Kempis opera omnia* (3 vols. in 1, 1607)—has been many times reprinted. A critical edition in 8 vols. by M. J. Pohl, has also been undertaken. The best accounts in English of Thomas à Kempis are those by S. Kettlewell (1882) and F. R. Cruise (1887), written from the Protestant and the Catholic standpoints respectively. A penny tract by F. R. Cruise, entitled *Outline of the Life of Thomas à Kempis* (1904), contains substantially all that is known concerning him. (T. M. L.)

THOMAS (d. 1100), archbishop of York, was a native of Bayeux, and is usually called Thomas of Bayeux. His father was a priest named Osbert, and Samson, bishop of Worcester from 1086 until his death in May 1112, was his brother. Owing largely to the generosity of Odo, bishop of Bayeux, Thomas studied in France, Germany and Spain and became known as a scholar; then he became one of Bishop Odo's officials and after 1066 one of William the Conqueror's chaplains, or secretaries. In 1070 he succeeded Aldred as archbishop of York, but declining to promise obedience to the archbishop of Canterbury, Lanfranc, the latter prelate refused to consecrate him. King William, however, induced him to submit and he was consecrated, but his profession of obedience was to Lanfranc personally and not to the archbishops of Canterbury. In 1071 both archbishops travelled to Rome for their palls and while there Thomas wished Pope Alexander II. to decree the equality of the sees of Canterbury and York. The pope, however, referred the dispute to a council of English prelates, and this met at Windsor at Whitsuntide 1072. It was then decided that the archbishop of Canterbury was the superior of the archbishop of York, who had no rights south of the Humber, but whose province included Scotland. But this decision did not put a period to the dispute. It broke out again, and in 1092 and again in 1093 Thomas protested against what he regarded as infringements of his archiepiscopal rights. The first of these occasions was over the dedication of the cathedral built by Remigius at Lincoln and the second was over the consecration of St Anselm to the archbishopric of Canterbury. In 1100, during Anselm's exile, Thomas reached London too late to crown Henry I., the ceremony having been hurriedly performed by Maurice, bishop of London, but his anger at this slight was soon appeased. He died at York on the 18th of November 1100. Thomas rebuilt the minster at York, where he appears to have been an excellent archbishop; he knew something of church music and wrote hymns.

Thomas had a nephew, Thomas, the son of his brother Samson, who was also archbishop of York. The younger Thomas became archbishop in 1108 and like his uncle he refused to promise obedience to the archbishop of Canterbury; his consecration was then delayed and the dispute was still unsettled when St Anselm died in April 1109. Henry I. and his bishops then decided against Thomas, who was forced to make the necessary promise and was consecrated in London in June 1109. He died at Beverley on the 24th of February 1114.

THOMAS, surnamed MAGISTER (*i.e.* officiorum),[1] also known as a monk by the name Theodulos Monachos, a native of Thessalonica, Byzantine scholar and grammarian and confidential adviser of Andronicus II. (1282–1328). His chief work, Ἐκλογὴ Ὀνομάτων καὶ Ῥημάτων Ἀττικῶν, is a collection of selected Attic words and phrases, partly arranged in alphabetical order, compiled as a help to Greek composition from the works of Phrynichus, Ammonius, Herodian and Moeris. He also wrote scholia on Aeschylus, Sophocles, Euripides (with life), and three of the comedies of Aristophanes; the scholia on Pindar, attributed to him in two MSS., are now assigned to Demetrius Triclinius. His speeches and letters consist partly of declamations on the usual sophistical themes, partly deal with contemporary historical events: an argument between the fathers of Cynegirus and Callimachus (two Athenians who fell at Marathon) as to which had the better claim to have the funeral oration pronounced over him first; a discussion on the duties of a king and of his subjects; a defence of the Byzantine general Chandrenos addressed to the emperor; a letter on the cruelties of the Catalans and Turks in Thessaly and Macedonia; a congratulatory letter to Theodorus Metochita; a panegyric on the king of Cyprus.

Editions of the Ἐκλογὴ by F. Ritschl (1832), C. Jacobitz (1833) and C. D. Beck (1836); other works in J. P. Migne, *Patrologia graeca*, cxlv.; see also C. Krumbacher, *Geschichte der byzantinischen Litteratur* (1897).

THOMAS OF CELANO, Franciscan friar and disciple and biographer of St Francis of Assisi. Born at Celano in the Abruzzi, he joined St Francis probably about 1214, and he appears to have been one of the first band of friars who went into Germany. He was commissioned by Gregory IX. to write the Life of St Francis, and in 1229 he completed the *First Legend*; in 1247 at the command of the minister general he composed the *Second Legend*, and a few years later the *Tract on the Miracles of St Francis*. He also composed in 1255 the *Legend of St Clare*; and he is one of those to whom the sequence *Dies irae* is attributed.

Thomas of Celano's writings on St Francis have been critically edited by E. d'Alençon in 1906; the value of this work is enhanced by the fact that critical opinion is veering round to the view that Thomas of Celano is the best authority for the life of the saint (see "Note on the Sources," appended to article FRANCIS OF ASSISI). An English translation (*The Lives of S. Francis of Assisi by Brother Thomas of Celano*) by A. G. Ferrers Howell appeared in 1908. All that is known of Thomas of Celano is brought together in Edouard d'Alençon's *Prolegomena*; see also introduction to Ferrers Howell's translation. (E. C. B.)

THOMAS OF ERCELDOUNE, called also THE RHYMER, and sometimes given the surname of LEARMONT (*fl.* ? 1220–? 1297), poet and prophet in the legendary literature of Scotland. The historical person of that name figures in two charters of the 13th century, and from these it appears that he owned lands in Erceldoune (now Earlstoun), in Berwickshire, which were made over by his son and heir on the 2nd of November 1294 to the foundation of the Holy Trinity at Soltra (or Soutra) on the borders of the same county. This would seem to imply that Thomas the Rhymer was already dead, but J. A. H. Murray, who edited *The Romance and Prophecies* (E.E.T.S., 1875), thinks that he was living three years later in a Cluniac priory in Ayrshire. He figures in the works of Barbour and Harry the Minstrel as the sympathizing contemporary of their heroes, and Walter Bower, who continued the *Scotichronicon* of Fordun, tells how he prophesied the death of Alexander III. in 1285. Barbour makes the bishop of St Andrews in 1306 express a hope that a prophecy of Thomas referring to Bruce will come true; and Wyntoun says that he foretold the battle of Kilblane. In the folk-lore of Scotland his name is associated with numerous fragments of verse of a gnomic and prophetic character. The romance of Thomas and the elf-queen was attributed to Erceldoune by Robert Mannyng de Brunne, but the earliest text, in the Auchinleck MS. in the Advocates' library, Edinburgh, is in a dialect showing southern forms, and dates from the beginning of the 14th century. It may be based on a genuine work of Thomas, a version by him of the widely diffused Tristan Saga. This text was published in 1804 by Sir Walter Scott, and was by him assigned to the Rhymer. The most widely accepted opinion is that it is a translation of a French original. The Rhymer's lands at Earlstoun are still identified. In 1840 died the last of a family named Learmont, which claimed descent from the poet. It may be noted that the Russian poet Michael Lermontov claimed Thomas of Erceldoune as his ancestor.

See J. A. H. Murray's edition of *The Romance and Prophecies* (E.E.T.S., 1875); Brandl's *Thomas of Erceldoune* (Berlin, 1880), and Kölbing's *Die nordische und die englische Version der Tristransage* (Heilbronn, 1882); also McNeill's *Sir Tristrem* (S.T.S., 1886); Lumby's *Early Scottish Prophecies* (E.E.T.S., 1870), and the reprint of the *Whole Prophesie of Scotland* (1603) by the Bannatyne Club (1833).

THOMAS OF MARGĀ, a Nestorian bishop and author of an important monastic history in Syriac, who flourished in the 9th century A.D. He was born early in the century, probably of Persian parents, in the region of Salakh to the north-east of Mosul. As a young man he became in 832 a monk of the famous Nestorian monastery of Beth 'Ābhē, which was situated at the confluence of the Great Zab with one of its tributaries, about 25 m. due east of Mosul. A few years later he was acting as secretary to Abraham, who had been abbot of Beth 'Ābhē, and was catholicus (patriarch) of the Nestorians from 837 to 850. At some date during these 13 years Thomas was promoted by Abraham to be bishop of Margā, a diocese in the same district as Beth 'Ābhē, and afterwards he was further advanced to be a metropolitan of Beth Garmai, a district farther to the south-east in the mountains which border the Tigris basin. It was during the period of his life at Beth 'Ābhē and his bishopric that he composed *The Book of Governors*, which is in the main a history of his own monastery, but includes lives of holy men in other parts of Mesopotamia and the regions east of the Tigris. The work was probably planned in imitation of the famous *Paradise* of Palladius, the history of Egyptian monasticism which had become well known to Syriac-speaking Christians in the version of 'Ānān-Īshō' (6th century).

The Book of Governors has been edited with an English translation and a copious introduction by E. W. Budge (2 vols., London, 1893), who claims that "it occupies a unique position in Syriac literature, and it fully deserves the veneration with which it has been and is still regarded by all classes of Nestorians to whom it is known." It gives a detailed history of the great monastery of Beth 'Ābhē during its three centuries of existence down to the author's time. It is full of interesting narratives of saintly men told in a naïve and candid spirit, and it throws much light on the history of Christianity in the Persian dominions. There is a later edition by P. Bedjan (Paris, 1901). (N. M.)

THOMAS, ARTHUR GORING (1850–1892), English musical composer, was the youngest son of Freeman Thomas and Amelia, daughter of Colonel Thomas Frederick. He was born at Ratton Park, Sussex, on the 20th of November 1850, and educated at Haileybury College. He was intended for the Civil Service, but delicate health interfered with his studies, and in 1873 he went to Paris to cultivate the musical talent he had displayed from an early age. Here he studied for two years with Émile Durand. In 1875 he returned to England, and in 1877 entered the Royal Academy of Music, where for three years he studied under Ebenezer Prout and Arthur Sullivan, winning twice the Lucas medal for composition. At a later period he received some instruction in orchestration from Max Bruch. His first published composition was a song, "Le Roi Henri," which appeared in 1871. An early comic opera, *Don Braggadocio* (libretto by his brother, C. I. Thomas), was apparently unfinished; some of the music in it was afterwards used for *The Golden Web*. A selection from his second opera, *The Light of the Harem* (libretto by Clifford Harrison), was performed at the Royal Academy of Music on the 7th of November 1879, with such success that Carl Rosa commissioned him to write

[1] For the duties of this important office, see J. B. Bury, *Later Roman Empire* (1889), i. 45.

Esmeralda (libretto by T. Marzials and A. Randegger), which was produced at Drury Lane on the 26th of March 1883. Two years later it was given (in German) at Cologne and Hamburg, and in 1890 (in French) at Covent Garden. On the 16th of April 1885 Rosa produced at Drury Lane Thomas's fourth and best opera, *Nadeshda* (libretto by Julian Sturgis), a German version of which was given at Breslau in 1890. A fifth opera, *The Golden Web* (libretto by F. Corder and B. C. Stephenson), slighter than its predecessors, was produced (after the composer's death) at Liverpool, Feb. 15, and at the Lyric Theatre, London, Mar. 11, 1893. Besides these dramatic works Thomas's chief compositions were a psalm, "Out of the Deep," for soprano solo and chorus (London, 1878); a choral ode, "The Sun Worshippers" (Norwich, 1881), and a suite de ballet for orchestra (Cambridge, 1887). A cantata, *The Swan and the Skylark,* was found in pianoforte score among his MSS. after his death: it was orchestrated by C. Villiers Stanford, and produced at the Birmingham Festival of 1894. His minor compositions include over 100 songs and duets. In 1891 Thomas became engaged to be married; shortly afterwards he showed signs of mental disease, and his career came to a tragic end on the 20th of March 1892. He was buried in Finchley cemetery. Goring Thomas occupies a distinct place among English composers of the 19th century. His music, which shows traces of his early French training, reveals a great talent for dramatic composition and a real gift of refined and beautiful melody. Personally the most amiable of men, he was most critical of his own work, never attempting anything for which he felt he was unfitted, and constantly revising and rewriting his compositions. (W. B. S.*)

THOMAS, CHARLES LOUIS AMBROISE (1811–1896), French musical composer, was born at Metz on the 5th of August 1811. He studied at the Paris Conservatoire, and won the Grand Prix de Rome in 1832. Five years later (in 1837) his first opera, *La Double échelle*, was produced at the Opéra Comique. For the next five-and-twenty years Thomas's productivity was incessant, and most of his operatic works belonging to this period enjoyed an ephemeral popularity. A few of these are still occasionally heard on the continent, such as *Le Caïd* (1849), *Le Songe d'une nuit d'été* (1850), *Psyché* (1857). The overture to *Raymond* (1851) has remained popular. So far the composer's operatic career had not been marked by any overwhelming success. He occupied a place among the recognized purveyors of operas in the French capital, but could scarcely claim to having achieved European renown. The production of *Mignon* at the Opéra Comique in 1866, however, at once raised Ambroise Thomas to the position of one of the foremost French composers. Goethe's touching tale had very happily inspired the musician; Mme Galli Marié, the original interpreter of the title-rôle, had modelled her conception of the part upon the well-known picture by Ary Scheffer, and *Mignon* at once took the fancy of the public, its success being repeated all over the continent. It has since remained one of the most popular operas belonging to the second half of the 19th century. Thomas now attempted to turn Shakespeare's *Hamlet* to operatic account. His opera of that name was produced with success at the Paris Opéra in 1868, where it enjoyed a long vogue. If the music is scarcely adequate to the subject, it nevertheless contains some of the composer's best work. The scene of the esplanade is genuinely dramatic, the part of Ophelia is poetically conceived, and the ballet music is very brilliant. Ambroise Thomas's last opera, *Françoise de Rimini*, was given at the Opéra in 1882, but has not maintained itself in the *répertoire.* Seven years later *La Tempête*, a ballet founded on Shakespeare's play, was produced at the same theatre. Ambroise Thomas succeeded Auber as director of the Paris Conservatoire in 1871. His music is often distinguished by refined touches which reveal a sensitive mind, and there is a distinct element of poetry in his *Mignon* and *Hamlet*, two operas that should suffice to keep the composer's memory green for some time to come. He died on the 12th of February 1896. (A. He.)

THOMAS, GEORGE (*c.* 1756–1802), British military adventurer in India. Thomas was born of poor parentage in Ireland in 1756, deserted from the British Navy in Madras, and made his way north to Delhi, where he took service under the begum Samru of Sardhana. Supplanted in her favour by a Frenchman, he transferred his allegiance to Appa Rao, a Mahratta chieftain, and subsequently set up an independent kingdom of his own in Hariana with his capital at Hansi. Thomas was a man of great personal strength and daring, and considerable military genius. In the turmoil of falling kingdoms in the India of that day his sword was always at the service of the highest bidder; but he had the virtues of his profession—he never betrayed an employer, was kind and generous to his soldiers, and was always ready to succour a woman in distress. He cherished dreams of conquering the Punjab, and fought one of his best campaigns against the Sikh chiefs; but he was finally defeated and captured by Sindhia's army under General Perron (*q.v.*). His iron constitution was broken by exposure and excessive drinking, and he died on his way down the Ganges on the 22nd of August 1802.

See Francklin, *Military Memoirs of Mr George Thomas* (1803); Compton, *Military Adventurers of Hindustan* (1892).

THOMAS, GEORGE HENRY (1816–1870), American general, was born in Southampton county, Virginia, on the 31st of July 1816. Graduating from West Point in 1840, he served as an artillery subaltern in the war against the Seminole Indians in Florida (1841), and in the Mexican War at the battles of Fort Brown, Resaca de la Palma, Monterey and Buena Vista, receiving three brevets for distinguished gallantry in action. From 1851 to 1854 he was an instructor at West Point. In 1855 he was appointed by Jefferson Davis, then secretary of war, a major of the 2nd Cavalry. His regimental superiors were A. S. Johnston, R. E. Lee and Hardee. All three resigned at the outbreak of the Civil War and Thomas was long in doubt as to his duty. He finally decided to adhere to the United States. He was promoted in rapid succession to be lieutenant-colonel and colonel in the regular army, and brigadier-general of volunteers. In command of an independent force in eastern Kentucky, on the 19th of January 1862, he attacked the Confederate General Zollicoffer at Mill Springs, and completely routed him, gaining by vigorous attack and relentless pursuit the first important Union victory in the West. He served under Buell and was offered, but refused, the chief command in the anxious days before the battle of Perryville. Under Rosecrans he was engaged at Stone River and was in charge of the most important part of the manœuvring from Decherd to Chattanooga. At the battle of Chickamauga (*q.v.*) on the 19th of September 1863 he achieved great distinction, his firmness on that disastrous field, where he gained the name of "The Rock of Chickamauga," being all that saved a terrible defeat from becoming a hopeless rout. He succeeded Rosecrans in command of the Army of the Cumberland shortly before the great victory of Chattanooga (*q.v.*), in which Thomas and his army played a most conspicuous part, his divisions under Sheridan, Wood and Baird carrying Missionary Ridge in superb style. In Sherman's advance through Georgia in the spring of 1864, the Army of the Cumberland numbered over 60,000 men present for duty. Thomas handled these with great skill in all the engagements and flanking movements from Chattanooga to Atlanta. When J. B. Hood broke away from Atlanta in the autumn of 1864, menaced Sherman's long line of communications and endeavoured to force Sherman to follow him, Sherman determined to abandon his communications and march to the sea, leaving to Thomas the difficult task of dealing with Hood. Thomas hastened back with a comparatively small force, racing with Hood to reach Nashville, where he was to receive reinforcements. At the battle of Franklin on the 30th of November 1864, a large part of Thomas's force, under command of Schofield, checked Hood long enough to cover the concentration at Nashville (*q.v.*). Here Thomas had to organize his force, which was drawn from all parts of the West and included many young troops and even quartermaster's employés. He declined to attack until his army was ready and the ice which covered the ground had melted sufficiently to enable his men to move. The whole of the North, and even General Grant himself, were impatient of the delay. General Logan was sent with an order to supersede Thomas, and soon afterwards Grant left the Army of the Potomac to take command in person. Before either arrived Thomas made his attack (December 15th–16th, 1864) and inflicted on Hood the most crushing defeat sustained in the open field by any army on either side in the whole war. Hood's army was completely ruined and never again appeared on the field. For this brilliant victory Thomas was made a major-general in the regular army and received the thanks of Congress. After the termination of the Civil War he commanded military departments in Kentucky and Tennessee until 1869, when he was ordered to command the division of the Pacific with headquarters at San Francisco. He died there of apoplexy, while writing an answer to an article criticizing his military career, on the 28th of March 1870.

Thomas was beloved by his soldiers, for whom he always had a fatherly solicitude. He was a man of solid rather than brilliant attainments; he remained in the army all his life, and never had any ambitions outside of it; the nickname of "Slow Trot Thomas" given him by the cadets at West Point characterized him physically and mentally; his mind acted deliberately, and his temperament was somewhat sluggish; but his judgment was accurate, his knowledge of his profession was complete in every detail, and when he had finally grasped a problem, and the time arrived for action, he struck his blow with extraordinary vigour and rapidity. The only two battles in which he was in chief command—Mill Springs and Nashville, one at the beginning and the other near the end of the war—were signal victories, without defect and above criticism. His service during the intervening three years of almost incessant conflict and manœuvring was marked by loyal obedience to his superiors, skilful command of his subordinates, and successful accomplishment of every task entrusted to him.

THOMAS, ISAIAH (1749–1831), American printer, was born in Boston, Massachusetts, on the 19th of January 1749. He was apprenticed in 1755 to Zechariah Fowle, a Boston printer, with whom, after working as a printer in Halifax, Portsmouth, New Hampshire, and Charleston, South Carolina, he formed a partnership in 1770. He issued in Boston the *Massachusetts Spy* three times each week, then (under his sole ownership) as a semi-weekly, and beginning in 1771, as a weekly which soon espoused the Whig cause and which the government tried to suppress. On the 16th of April 1775 (three days before the battle of Concord, in which he took part) he took his presses and types from Boston and set them up at Worcester, where he was postmaster for a time; here he published and sold books and built a paper-mill and bindery, and he continued the paper until about 1802 except in 1776–1778 and in 1786–1788. The *Spy* supported Washington and the Federalist party. In Boston Thomas published, in 1774, the *Royal American Magazine*, which was continued for a short time by Joseph Greenleaf, and which contained many engravings by Paul Revere; and in 1775–1803 the *New England Almanac*, continued until 1819 by his son. He set up printing houses and book stores in various parts of the country, and in Boston with Ebenezer T. Andrews, published the *Massachusetts Magazine*, a monthly, from 1789 to 1793. At Walpole, New Hampshire, he published the *Farmer's Museum*. About 1802 he gave over to his son, Isaiah Thomas, junr., his business at Worcester including the control of the *Spy*. Thomas founded in 1812 the American Antiquarian Society. He died in Worcester on the 4th of April 1831.

His *History of Printing in America, with a Biography of Printers, and an Account of Newspapers* (2 vols., 1810; 2nd ed., 1874, with a catalogue of American publications previous to 1776 and a memoir of Isaiah Thomas, by his grandson B. F. Thomas) is an important work, accurate and thorough.

THOMAS, PIERRE (1634–1698), sieur du Fossé, French scholar and author, was the son of a master of accounts at Rouen. He was sent as a child to be educated at Port Royal, and there he received his final bent towards the life of a recluse, and even of a hermit, which drew him to establish himself in the neighbourhood of Port Royal des Champs. In 1661 he came to Paris, and in 1666 was arrested along with I. L. Le Maistre (de Sacy), and after a month in the Bastille was exiled to his estate of Fossé. He later made yearly visits to Paris. Apart from his collaboration with de Sacy, Thomas wrote some hagiographic works and left Mémoires (1697–1698 and again 1876–1879), which are highly praised by Ste Beuve as being a remarkable mirror of the life at Port Royal.

THOMAS, SIDNEY GILCHRIST (1850–1885), British inventor, was born on the 16th of April 1850 at Canonbury, London. His father, a Welshman, was in the civil service, and his mother was the daughter of the Rev. James Gilchrist. His father's death leaving his family with a considerably reduced income, he gave up his original idea of becoming a doctor and obtained an appointment as a police court clerk, which he held till May 1879. During these twelve years, besides the work of a busy police court, which brought him into intimate contact with social problems, he found time to study chemistry, and attended lectures at the Birkbeck Institute. He set himself to solve the problem of eliminating phosphorus from iron by means of the Bessemer converter, and by the end of 1875 was convinced that he had discovered a method. He communicated his theory to his cousin, P. C. Gilchrist, who was chemist to iron works in Wales, and experiments were made, which proved satisfactory. Edward Martin, manager of the Blaenavon Works, gave facilities for conducting the experiments on a larger scale and undertook to help in taking out a patent. In March 1878, the first public announcement of the discovery was made at the meeting of the Iron and Steel Institute, but without attracting much attention; and in September a paper was written by Thomas and Gilchrist on the "Elimination of Phosphorus in the Bessemer Converter" for the autumn meeting of this institute, but was not read till May 1879. Thomas, however, made the acquaintance of E. W. Richards, the manager of Bolckow Vaughan & Co.'s works at Cleveland, Yorkshire, whom he interested in the process, and from this time the success of the invention was assured and domestic and foreign patents were taken out. The "basic process" invented by Thomas was especially valuable on the continent of Europe, where the proportion of phosphoric iron is much larger than in England, and both in Belgium and in Germany the name of the inventor became more widely known than in his own country. In America, although non-phosphoric iron largely predominates, an immense interest was taken in the invention. But Thomas had been overworking for years, and his lungs became affected. A long sea voyage and a residence in Egypt proved unavailing to restore his health and he died in Paris on the 1st of February 1885. He had what W. E. Gladstone, in a review of the *Memoirs* published in 1891, described as an "enthusiasm of humanity," and he left his fortune to be used for the promotion of philanthropic work. A police court mission was endowed in his memory.

See *Memoirs and Letters of Sidney Gilchrist Thomas* (1891), ed. by R. W. Burnie.

THOMAS, THEODORE (1835–1905), American musician, was born in Esens, Germany, on the 11th of October 1835. His early musical training was received chiefly from his father. At the age of five he made his first public appearance as a violinist. In 1845 he was taken to America by his parents, and became first violin in the orchestra that accompanied Jenny Lind in 1850, Sontag in 1852 and Grisi and Mario in 1854. In 1862 he began to organize his own orchestra, and from 1864 to 1878 were performed a series of symphony concerts inaugurated by him in Irving Hall, which were regarded as one of the great musical institutions of New York City. His "summer night" concerts begun in 1866 in Terrace Garden were continued in Central Park. From 1855 to 1868 he took part in a series of chamber music concerts in New York. In the latter year his orchestra made its first tour, and continued to give concerts in various American cities until it was disbanded in 1888. To Theodore Thomas is largely due the popularization of Wagner's works in America, and it was he who founded the Wagner union in 1872. During most of the seasons from 1877 to 1891 he was conductor of the New York Philharmonic Society, and from 1862 to 1891, of the Brooklyn Philharmonic Society. He was director of the Cincinnati College of Music (1878–1879), conductor of the American Opera Company (1886–1887), and for more than thirty years (1873–1904) the conductor of the biennial May festivals at Cincinnati. In 1891 he removed to Chicago, and became the conductor of the Chicago Orchestra; in 1893 he was musical director of the Columbian Exposition. He died on the 4th of January 1905.

THOMAS, WILLIAM (d. 1554), English soldier and writer, was probably a native of Radnorshire and was educated at Oxford. In 1544 he went to Italy, where he spent the greater part of the next five years, and in April 1550, soon after his return to England, he was made one of the clerks of the privy council; he also taught the science of politics to the young king Edward VI., for whose instruction he wrote some treatises and some "commonplaces of state." Being a strong Protestant he took part in the rising against Queen Mary led by Sir Thomas Wyat in 1554, being captured and thrown into the Tower of London. Having whilst in prison tried to commit suicide and been tortured on the rack in the hope of incriminating the princess Elizabeth, he was found guilty and was hanged at Tyburn on the 18th of May 1554.

During his residence at Bologna Thomas, who was a very learned man, wrote *Il Pellegrino inglese*, published in 1552. This is a valuable and interesting defence of Henry VIII. by a contemporary and it originated in a discussion between the author and some Italian gentlemen. He also prepared an English version of this work, but this was not published during his lifetime. As *The Pilgrim: a dialogue of the life and actions of King Henry VIII.*, it was edited with notes by J. A. Froude and appeared in 1861. It had previously been edited by A. D'Aubant, who had added to it the six treatises written for Edward VI. and had called the whole *The Works of William Thomas* (1774). Of his other writings perhaps the most important is *The Historie of Italie* (1549), and his *Principal Rules of the Italian Grammar with a Dictionarie for the better understanding of Boccace, Petrarcha and Dante* (1550, 1560, 1562 and 1567) may also be mentioned. This was the first work of its kind in English. Thomas made an English translation of Josafat Barbaro's account of his voyages, Barbaro being a Venetian traveller who died in 1494. With an introduction by Lord Stanley of Alderley this was published by the Hakluyt Society in a volume of *Travels to Tana and Persia* (London, 1873). See John Strype, *Ecclesiastical Memorials* (Oxford, 1822).

Thomas has a namesake, William Thomas (1613–1689), bishop of St David's from 1677 to 1683 and bishop of Worcester from 1683 to 1689. He was one of the bishops who refused to take the oaths of allegiance to William and Mary in 1689 and was suspended, but in the midst of the dispute he died on the 25th of June 1689 (see NONJURORS). The bishop's grandson was William Thomas (1670–1738), the Worcestershire antiquary.

THOMASIUS, CHRISTIAN (1655–1728), German jurist and publicist, was born at Leipzig on the 1st of January 1655, and was educated by his father, Jakob Thomasius (1622–1684), at that time head master of the Thomasschule. Through his father's lectures Christian came under the influence of the political philosophy of Hugo Grotius and Samuel Pufendorf, and continued the study of law at Frankfort-on-Oder. In 1684 he commenced the career of professor of natural law at Leipzig, and soon attracted attention by his abilities, but particularly by his daring attack upon traditional prejudices, in theology and jurisprudence. In 1687 he made the daring innovation of lecturing in German instead of Latin, and in the following year published a monthly periodical (*Scherzhafte und ernsthafte, vernünftige und einfällige Gedanken über allerhand lustige und nützliche Bücher und Fragen*) in which he ridiculed the pedantic weaknesses of the learned, taking the side of the Pietists in their controversy with the orthodox, and defending mixed marriages of Lutherans and Calvinists. In consequence of these and other views, he was denounced from the pulpits, forbidden to lecture or to write (May 10, 1690), and his arrest was ordered. The latter he escaped by flight to Berlin, and the elector Frederick III. offered him a refuge in Halle, with a salary of 500 talers and the permission to lecture. He took part in founding the university of Halle (1694), where he became second and then first professor of law and rector of the university. He was one of the most esteemed university teachers and influential writers of his day. He died, after a successful and honourable career, on the 23rd of September 1728.

Though not a profound and systematic philosophical thinker, Thomasius prepared the way for great reforms in philosophy, and, above all, in law, literature, social life and theology. It was his mission to introduce a rational, common-sense point of view, and to bring the high matters of divine and human sciences into close and living contact with the everyday world. He thus created an epoch in German literature, philosophy and law, and Spittler opens with him the modern period of ecclesiastical history. He made it one of the aims of his life to free politics and jurisprudence from the control of theology, and fought bravely and consistently for freedom of thought and speech on religious matters. He is often spoken of in German works as the author of the "territorial system," or Erastian theory of ecclesiastical government. But he taught that the state may interfere with legal or public duties only, and not with moral or private ones. He would not have even atheists punished, though they should be expelled the country, and he came forward as an earnest opponent of the prosecution of witches and of the use of torture. In theology he was not a naturalist or a deist, but a believer in the necessity of revealed religion for salvation. He came strongly under the influence of the pietists, particularly of Spener, and there was a mystic vein in his thought; but other elements of his nature were too powerful to allow him to attach himself wholly to that party.

Thomasius's most popular and influential German publications were his periodical already referred to (1688–1689); *Einleitung zur Vernunftlehre* (1691, 5th ed. 1719); *Vernünftige Gedanken über allerhand auserlesene und juristische Händel* (1720–1721); *Historie der Weisheit und Torheit* (3 vols., 1693); *Kurze Lehrsätze von dem Laster der Zauberei mit dem Hexenprozess* (1704); *Weitere Erläuterungen der neueren Wissenschaft anderer Gedanken kennen zu lernen* (1711).

See Luden, *Christian Thomasius nach seinen Schicksalen und Schriften* (1805); H. Dernburg, *Thomasius und die Stiftung der Universität Halle* (1865); B. A. Wagner, *Thomasius, ein Beitrag zur Würdigung seiner Verdienste* (1872); Nicoladoni, *Christian Thomasius. Ein Beitrag zur Geschichte der Aufklärung* (Berlin, 1888); and E. Landsberg, *Zur Biographie von Christian Thomasius* (1894).

THOMASON, GEORGE (d. 1666), English book and tract collector, was a London bookseller, whose life contains few items of interest save the fact that he was concerned in a royalist plot in 1651. He is famous, however, as the man who brought together the great collection of books and tracts published during the time of the Civil War and the Commonwealth; this was formerly called the "King's Pamphlets," but is now known as the "Thomason Collection." During the years just before the outbreak of war a great number of writings covering every phase of the questions in dispute between king and people were issued, and in 1641 Thomason began to collect these. Working diligently at his task for about twenty years, he possessed nearly 23,000 separate publications in 1662, and having arranged these in chronological order he had them bound in 1983 volumes. After many vicissitudes the collection was bought in 1761 from his descendants by George III., who presented it to the British Museum, where it now is (see NEWSPAPERS). Thomason died in London in April (1666).

THOMASVILLE, a city and the county-seat of Thomas county, Georgia, U.S.A., about 200 m. S.W. of Savannah. Pop. (1900), 5322, of whom 3296 were negroes; (1910), 6727. Thomasville is served by the Atlanta, Birmingham & Atlantic, the Atlantic Coast Line and the Florida Central railways. The city is attractively situated (about 250 ft. above the sea) on a high plateau, is surrounded by pine forests, and is a well-known winter resort. There are fine drives in the vicinity. Thomasville has a city hospital, a public library (1876) and a good public school system, and is the seat of Young's College (for girls), which was founded by E. Remer Young, a wealthy planter of Thomas county, was incorporated in 1869 and was opened in 1871, and of the Vashti industrial school (1903) for girls, maintained by the Women's home mission society of the Methodist Episcopal Church, South. The city has a large trade in lumber, especially yellow pine; other products of the region are cotton, sugar-cane, tobacco, melons, fruits and vegetables. The municipality owns and operates the water-works and electric-lighting plant; the water supply is obtained in part from artesian wells 1900 ft.

deep. Thomasville was settled about 1825, was incorporated as a town in 1831, and was chartered as a city in 1889.

THOMOND, EARL AND MARQUESS OF, Irish titles borne by the great family of O'Brien, the earldom from 1543 to 1741 and the marquessate from 1800 to 1855. Thomond, or Tuaidh-Muin, was one of the three principalities of Munster, forming the northern part of the province. Its earls were descended from Turlough O'Brien (*c.* 1009–1086), king of Munster, and through him from the celebrated king of Ireland, Brian Boroimhe. Turlough's descendants, Conchobhar O'Brien (d. 1267) and Brian Ruadh O'Brien (d. 1276), kings of Thomond, were both typical Irish chieftains. Conchobhar's tomb and effigy with a crown are still to be seen in the ruined abbey of Corcomroe, Co. Clare. His descendant Conor O'Brien (d. 1539), prince of Thomond, took part in the feud between the great families of Fitzgerald and Butler and was the last independent prince of Thomond. It is interesting to learn that in 1534, when he was in some straits, he wrote to the emperor Charles V. offering to submit to his authority. Conor's brother, Murrough O'Brien (d. 1551), prince of Thomond, the succeeding chief of the race, gave up his "captainship, title, superiority and country" to Henry VIII. in 1543, when he was created earl of Thomond. By special arrangement the earldom descended, not to his son Dermod, but to his nephew, Donough, who became the 2nd earl. Dermod, however, inherited the barony of Inchiquin, which was conferred upon his father at the same time as the earldom.

Conor O'Brien, the 3rd earl (*c.* 1534–*c.* 1582), was for some years at the outset of his career, harassed by the attacks of his discontented kinsmen. Then in his turn he rose against the English, but was defeated and fled to France; in 1571, however, he was pardoned and formally surrendered his lands to Elizabeth. One of his younger sons was Daniel O'Brien (*c.* 1577–*c.* 1664) who, after loyally serving Charles I. and Charles II., was created Viscount Clare in 1663. His grandson Daniel, the 3rd viscount (d. 1691) served James II. in Ireland, being outlawed and deprived of his estates by the English parliament. The three succeeding viscounts Clare all distinguished themselves in the service of France. Daniel, the 4th viscount, was mortally wounded at the battle of Marsaglia in 1693; his brother Charles, the 5th viscount (d. 1706), was killed at the battle of Ramillies; and the latter's son Charles, the 6th viscount (1699–1761) after a brilliant military career, was made a marshal of France in 1757. When Charles, the 7th viscount, died in 1774 the title became extinct.

Donough O'Brien, the 4th earl (d. 1624), called the "great earl," was the son and successor of the 3rd earl. He served England well in her warfare with the rebellious Irish during the closing year of Elizabeth's reign and was made president of Munster in 1605. He had two sons, Henry, the 5th earl, (d. 1639) and Barnabas, the 6th earl (d. 1657). During the Irish rebellion of 1640–41 Barnabas showed a prudent neutrality, and then joined Charles I. at Oxford, where in 1645 he was created marquess of Billing, but the patent never passed the great seal and the title was never assumed. The succeeding earls were Barnabas's son Henry (*c.* 1621–1691) and Henry's grandson Henry (1688–1741) who was created an English peer as Viscount Tadcaster. When he died the earldom of Thomond became extinct.

The estates of the earldom descended to the last earl's nephew, Percy Wyndham (*c.* 1713–1774), a younger son of Sir William Wyndham, Bart. He took the additional name of O'Brien and was created earl of Thomond in 1756. When he died unmarried the title again became extinct.

In 1800 Murrough O'Brien, 5th earl of Inchiquin (*c.* 1724–1808), was created marquess of Thomond. He was succeeded by his nephew William (*c.* 1765–1846) who was created a British peer as Baron Tadcaster in 1826. His brother James, the 3rd marquess (*c.* 1768–1855), was an officer in the navy and became an admiral in 1853. When he died the marquessate became extinct.

See John O'Donoghue, *Historical Memoirs of the O'Briens* (Dublin, 1860).

THOMPSON, FRANCIS (1860–1907), English poet, was born at Ashton, Lancashire, in 1860. His father, a doctor, became a convert to Roman Catholicism, following his brother Edward Healy Thompson, a friend of Manning. The boy was accordingly educated at Ushaw College, near Durham, and subsequently studied medicine at Owens College, Manchester; but he took no real interest in the profession of a doctor and was bent on literary production. A period of friendlessness and failure (from the point of view of "practical life") followed, in which he became a solitary creature who yet turned his visions of beauty into unrecognized verse. It was not till 1893 that, after some five obscure years, in which he was brought to the lowest depths of destitution and ill health, his poetic genius became known to the public. Through his sending a poem to the magazine *Merrie England*, he was sought out by Mr and Mrs Wilfrid Meynell and rescued from the verge of starvation and self-destruction, and these friends of his own communion, recognizing the value of his work, gave him a home and procured the publication of his first volume of *Poems* (1893). His debt to Mrs Meynell was repaid by some of his finest verse. The volume quickly attracted the attention of sympathetic critics, in the *St James's Gazette* and other quarters, and Coventry Patmore wrote a eulogistic notice in the *Fortnightly Review* (Jan. 1894). An ardent Roman Catholic, much of Francis Thompson's verse reminded the critics of Crashaw, but the beauty and splendid though often strange inventiveness of his diction were immediately recognized as giving him a place by himself among contemporary poets, recalling Keats and Shelley rather than any of his own day. Persistent ill health limited his literary output, but *Sister Songs* (1895) and *New Poems* (1897) confirmed the opinion formed of his remarkable gifts. But his health was hopelessly broken down by tuberculosis. Cared for by the friends already mentioned, he lived a frail existence, chiefly at the Capuchin monastery at Tanlasapt, and later at Storrington; and on the 13th of November 1907 he died in London. He had done a little prose journalism, and in 1905 published a treatise on *Health and Holiness*, dealing with the ascetic life; but it is with his three volumes of poems that his name will be connected. Among his work there is a certain amount which can justly be called eccentric or unusual, especially in his usage of poetically compounded neologisms; but nothing can be purer or more simply beautiful than "The Daisy," nothing more intimate and reverent than his poems about children, or more magnificent than "The Hound of Heaven." For glory of inspiration and natural magnificence of utterance he is unique among the poets of his time. (H. Ch.)

THOMPSON, SIR HENRY, Bart. (1820–1904), English surgeon, was born at Framlingham, Suffolk, on the 6th of August 1820. His father wished him to enter business, but circumstances ultimately enabled him to follow his own desire of becoming a physician, and in 1848 he entered the medical school of University College, London. There he had a brilliant career, and obtained his degree at London University in 1851 with the highest honours in anatomy and surgery. In 1851 he married Miss Kate Loder, a talented pianist, who, though stricken with paralysis soon afterwards, was always a devoted helpmate to him. In 1853 he was appointed assistant surgeon at University College Hospital, becoming full surgeon in 1863, professor of clinical surgery in 1866, and consulting surgeon in 1874. In 1884 he became professor of surgery and pathology in the Royal College of Surgeons, which in 1852 had awarded him the Jacksonian prize for an essay on the *Pathology and Treatment of Stricture of the Urethra*, and again in 1860 for another on the *Health and Morbid Anatomy of the Prostate Gland*. These two memoirs indicate the department of medical practice to which he devoted his main attention. Specializing in the surgery of the genito-urinary tract, and in particular in that of the bladder, he went to Paris to study under Civiale, who in the first quarter of the 19th century proved that it is possible to crush a stone within the human bladder, and after his return he soon acquired a high reputation as a skilful operator in that class of disease. In 1863, when the king of the Belgians was suffering from stone, he was called to Brussels to consult in the case, and after some difficulties was allowed to perform the operation of lithotrity: this was quite successful, and in recognition of his skill Thompson was appointed surgeon-extraordinary to the king, an appointment which was continued by Leopold II. Nearly ten years later he carried out a similar operation on the emperor Napoleon, who, however, died four days after the second crushing, not from the surgical interference, as was proved by the post-mortem examination, but from uraemic poisoning. Besides devising various operative improvements in the treatment of the disorders which were his speciality, Sir Henry Thompson wrote various books and papers dealing with them, including *Clinical Lectures on Diseases of the Urinary Organs*, *Practical Lithotomy and Lithotrity*, *Tumours of the Bladder*, *Suprapubic Lothotomy*, and *Preventive Treatment of Calculous Disease*. Among other books of a medical character that came from his pen were *Food and Feeding*, and *Diet in Relation to Age and Activity*, both of which passed through a number of editions. In 1874 he took a foremost part in founding the Cremation Society of England, of which he was the first president; and not only was he active in urging the advantages of cremation as a means of disposing of the body after death, but also did much towards the removal of the legal restrictions by which it was at first sought to prevent its practice in England. On various occasions he denounced the slackness and inefficiency of the methods of death-certification prevalent in Great Britain, and in 1892 his agitation was instrumental in procuring the appointment of a select committee to inquire into the matter; its report, published in the following year, in great measure confirmed his criticisms and approved the remedies he suggested. But medicine and hygiene by no means exhaust the list of Sir Henry Thompson's activities. In art he was an accomplished sketcher and, moreover, an amateur of painting whose pictures were hung at the Royal Academy and the Paris Salon. About 1870 he began to get together his famous collection of china, in particular of old blue and white Nanking; this in time became so large that he could no longer find room for it, and most of it was sold. A catalogue of it, illustrated by himself and Mr James Whistler, was published in 1878. In his famous "octaves" he may be said to have elevated the giving of dinner parties into a fine art. The number of courses and of guests was alike eight, and both were selected with the utmost care and discrimination to promote the "feast of reason and the flow of soul." In literature, in addition to more serious works, he produced two novels—*Charley Kingston's Aunt* (1885) and *All But* (1886)—which met with considerable success. In science he became a devotee of astronomy, and for a time maintained a private observatory in his house at Molesey. He further did much to promote astronomical study in Great Britain by presenting Greenwich Observatory with some of the finest instruments now among its equipment, his gifts including a photoheliograph of 9-in. aperture; a 30-in. reflecting telescope, and a large refracting telescope having an object-glass of 26-in. diameter and a focal length of 22½ ft. The offer of the last instrument was made in 1894. Its manufacture was undertaken by Sir Howard Grubb of Dublin, and its erection was completed in 1897. It added greatly to the instrumental resources of Greenwich, especially for photographic work, and its importance may be gauged from the fact that both in aperture and focal length it is double the size of any instrument possessed by the observatory at the time it was put in place. That Sir Henry Thompson, who was knighted in 1867, received a baronetcy in 1899 was probably not unconnected with the presentation of this telescope to the national observatory. Thompson died on the 18th of April 1904. His family consisted of an only son, Herbert, a barrister and well-known egyptologist, who succeeded to the baronetcy, and two daughters, of whom the elder (author of a valuable *Handbook to the Public Picture Galleries of Europe*, first published in 1877), married Archdeacon Watkins of Durham, and the younger married the Rev. H. de Candole.

THOMPSON, SIR JOHN SPARROW (1844–1894), Canadian jurist and statesman, was born at Halifax, Nova Scotia, on the 10th of November 1844, of Irish descent. At fifteen he entered a lawyer's office, and in 1865 was called to the provincial bar. In 1871 he incurred much odium by leaving the Methodist Church, in which he had been prominent, and becoming a Roman Catholic, a change dictated solely by religious motives. In 1877 he was elected to the local legislature for Antigonish as a Conservative, and in 1878 became attorney-general. In May 1882 he became premier, but in June was defeated at the general election, though retaining his own seat, and in July was made a judge of the provincial Supreme Court. In September 1885, he was appointed minister of justice in the Federal cabinet, and soon after was elected member for Antigonish. In 1886 he successfully defended in the Federal parliament the hanging of Louis Riel (*q.v.*), which had greatly angered the French Roman Catholics; in 1887–1888, together with Mr Joseph Chamberlain and Sir Charles Tupper, he arranged a Fisheries Treaty with the American commissioners, which was afterwards thrown out by the United States Senate. During the following years he defended the government with great skill in various politico-religious disputes, and in November 1892 succeeded Sir John Abbott as premier of Canada. The length of time during which the Conservatives had held office had gathered around many parasites, and Thompson was compelled to face charges, some of them true, against prominent Conservatives. He promptly announced his intention to "lop the mouldering branches away," and would probably have reorganized his party, but on the 12th of December 1894 he dropped dead at Windsor Castle, a few minutes after having been sworn in by Queen Victoria as a member of the privy council.

Though a quiet man who did not advertise, few Canadian statesmen have done so much honest and solid work. In 1892 he finished the codification of the Canadian criminal code; in 1893 his firmness and knowledge as British arbitrator at Paris on the Bering Sea dispute between Great Britain and the United States were of great service.

His *Life* has been written by J. C. Hopkins (Toronto, 1895).

THOMPSON, LAUNT (1833–1894), American sculptor, was born at Abbeyleix, Ireland, on the 8th of February 1833. In 1847 he emigrated to the United States, and settled with his mother at Albany, New York. After studying anatomy in the office of a physician, Dr Armsby, he spent nine years in the studio of the sculptor, E. D. Palmer. In 1857 he opened a studio in New York, and in 1862 became a National Academician. He visited Rome in 1868–1869, and from 1875 to 1887 was again in Italy, living for most of the time at Florence. He died at Middletown, New York, on the 26th of September 1894. Among his important works are: "Napoleon the First," at the Metropolitan Museum, New York; "Abraham Pierson," first president of Yale University, New Haven, Connecticut; an equestrian statue of General A. E. Burnside, Providence, Rhode Island; "General Winfield Scott," Soldiers' Home, Washington, D.C.; "Admiral S. F. Du Pont" (Washington, D.C.); "General John Sedgwick" (West Point, N.Y.); a medallion portrait of General John A. Dix; and portrait busts of James Gordon Bennett, William Cullen Bryant, S. F. B. Morse, Edwin Booth as Hamlet, Stephen H. Tyng and Robert B. Minturn.

THOMPSON, THOMAS PERONNET (1783–1869), English political writer and mathematician, was born at Hull in 1783. He was educated at the Hull grammar school, and in October (1798) entered Queens' College, Cambridge. He entered the navy as midshipman in the "Isis" in 1803, but in 1806 exchanged to the army. Through his acquaintance with William Wilberforce, he was appointed governor of Sierra Leone in 1808, but was recalled on account of his hostility to the slave trade. In 1812 he returned to his military duties, and, after serving in the south of France, was in 1815 attached as Arabic interpreter to an expedition against the Wahabees of the Persian Gulf, with whom he negotiated a treaty (dated Jan. 1820) in which the slave trade was for the first time declared piracy. He was promoted major in 1825, lieutenant-colonel in 1829 and major-general in

1854. He entered parliament as member for Hull (1835–1837), and afterwards sat for Bradford (1847–1852, 1857–1859). He took a prominent part in the corn-law agitation, his *Catechism of the Corn Laws* (1827) being by far the most effective pamphlet published on the subject. In 1829 he became the proprietor of the *Westminster Review*, to which he contributed a large number of articles, republished in 1842 in six volumes, under the title *Exercises, Political and Others*. His mathematical publications were of a somewhat eccentric kind. He published a *Theory of Parallels* (1844), and was also the author of *Geometry without Axioms*, in which he endeavoured to "get rid" of axioms and postulates. His new *Theory of Just Intonation* (1850) was, however, a contribution of great value to the science of musical acoustics, and went through many editions. It may be said to have formed the basis of the tonic sol-fa system of music. He died at Blackheath, near London, on the 7th of September 1869.

See Colonel C. W. Thompson's memoir in the *Proc. Roy. Soc.* (1869).

THOMPSON, WILLIAM HEPWORTH (1810–1886), English classical scholar and master of Trinity College, Cambridge, was born at York on the 27th of March 1810. He was privately educated before entering the university. In 1834 he became a fellow of Trinity, in 1853 professor of Greek (to which a canonry in Ely Cathedral was then for the first time attached), and in 1866 master of his college. With the exception of the year 1836, when he acted as headmaster of a newly established school in Leicester, his life was divided between Cambridge and Ely. He died at the master's lodge on the 1st of October 1886. Thompson proved a worthy successor to Whewell; the twenty years of his mastership were years of progress, and he himself took an active part in the abolition of tests and the reform of university studies and of the college statutes. As a scholar he devoted his attention almost entirely to Plato; and his *Phaedrus* (1868) and *Gorgias* (1871), with especially valuable introductions, still remain the standard English editions of these two dialogues. He also edited (1856) from the author's MSS. *Lectures on the History of Ancient Philosophy* by William Archer Butler (1814–1848; lecturer on moral philosophy at Trinity College, Dublin), the value of which was greatly enhanced by Thompson's notes.

See article by J. W. Clark in *Dict. Nat. Biog.*; and J. E. Sandys, *History of Classical Scholarship* (1908), vol. iii.
